Now, then, what is the obvious and scientific way of solving this problem? We solved it by taking a standard motor and equipping it first with a set of pistons which we felt sure, because of their great clearance, would slap. A hard road test showed that they did. These pistons were then removed and

larger ones by a couple of thousandths substituted and the same routine gone through. This process was continued until the slap disappeared. We then had found our upper limit of clearance. From here the process was continued, until finally the clearance became so small that there was a perceptible drag in the motor and then seizure occurred. We had thus found the lower limit of clearance. Observations taken all during these tests gave indisputable evidence as to what was the best clearance to use, or, to be more exact, what was the proper size piston for that size cylinder. Could anything be simpler or more accurate?

A. L. A. M. STANDARDIZATION ACCOMPLISHMENTS

FROM COKER F. CLARKSON ON THE SUBJECT.

Editor THE AUTOMOBILE:

It is hard to account for the reply given to H. A. Morris, on page 583 of the April 8 issue, in answer to the inquiry as to what the Association of Licensed Automobile Manufacturers has done in the way of standardization of parts.

It is well known that during recent years the A. L. A. M. has annually compiled for its members new specifications for the various materials used in automobile parts, resulting in the use by its members of stronger and more elastic metals. The result of this is seen in what the association cars have done in ordinary touring service and in contests.

The engineers and master mechanics of the association members have been quick to draw their accurate and logical conclusion from the data on various engineering subjects, jointly and severally submitted and discussed at their periodical meetings during recent years. These men are as able and progressive as any body of men in the world, and any statement tending to belittle their work can only reflect on the man who makes it. The generously given and effective co-operative work of these men has probably never been surpassed. At any rate, it has been characterized by many well qualified to judge as unique and without parallel.

As to standardization, it must be remembered that, fundamentally, standards are not spontaneous products, but what is indicated as best in long practice, and it is reasonable to assume can be used by the average manufacturer, both in the line of suitability primarily and as related to best practice. The adoption and promulgation three years ago of the A. L. A. M. screw standard was an event which indicates as well as anything else the competency of the association engineers to take the responsibility of passing alone and unaided upon a broad engineering subject. There has been a demand for at least forty years for a fine pitch screw standard. The matter not only lay dormant but was becoming more complicated every day because various kinds of machinery subject in use to great vibration demanded a thread of relatively fine pitch compared to that laid down in the old United States standard, and various more or less used fine pitch screw threads sprang up. There was also a long-continued unsatisfied demand for a properly designed castle nut. Incidentally the progress of automobile construction required stronger and tougher material, allowing less weight and neater appearance of screw for a given piece of work.

The A. L. A. M. has been absolutely the protagonist of this standard. It issues the only official edition of it and has carried on the mass of consequent communications with people in various lines of business throughout the world as to the details of it—such as matters of master gages, source of supply of both raw and finished material, taps and dies, and the best practice in drill sizes, etc. This screw standard met a crying want and has been an unqualified success. The propriety of its increasingly occupying its field must be more and more recognized.

The statement that the A. L. A. M. standard spark plug shell is different from all previous sizes is absolutely wrong. The A. L. A. M. standard spark plug has been as successful as the screw standard. Primarily it is what has been for some years known in the trade—since the start of the industry practically—as the Autocar plug.

Standardization is a word which carries a note of joy to the heart of every mechanic and every engineer; has been a long-cherished dream of the motoring fraternity; expounded as a doctrine; taught as a theory; discussed as a possibility, and advertised as an accomplishment ever since the automobile industry began to take shape as such. It is obvious that in this sense standardization may be a hobby. It is equally obvious that the A. L. A. M. engineers deserve credit for what they have had the sense not to standardize, as well as for the positive creative standards brought about.

It is easy to say, and it has been said for years, that control should be standardized, but it is not easy and it has not yet been considered feasible to do so, owing to the viewpoint of the different manufacturers as each in his light sees the demands of the public. To-day some people believe that for the high gear the change speed lever should be in one position; others are confident that it should be in another. Such features of construction as spark and throttle levers, axles and wheels, must of necessity be boiled down by time to the best practice. They are purely matters of design and preference, and distinct from the subject matter of a standard dealing with ratios or measurements after one design or form of a part has been practically universally accepted.

The function of standardization is in reducing the cost of and facilitating production, which is made possible by the fact that standardized parts, or tools with which they are made, are kept in stock at low prices relatively; and in the less cost and time involved in the replacement of parts by repairmen and users.

ASS'N OF LICENSED AUTOMOBILE MFRS.,
New York City. COKER F. CLARKSON.

E. T. BIRDSALL ON STANDARDIZING.

Editor THE AUTOMOBILE:

I desire to take issue with you on the answer to letter No. 1,820, April 8. In that answer it is stated that the mechanical branch of the A. L. A. M. has only made a small start towards standardization of automobile parts. If all the screws, bolts, nuts, yoke and rod ends, levers, spark plugs, and Q. D. rims on a car constitute a small part, then my idea of proportion and that of your writer's are far apart.

The yoke and rod ends were not standardized for the purpose of getting lower prices on forgings, but to get parts that were correctly designed for their work, and of such sizes as were needed in automobile construction. If I remember rightly, the price of these improved forgings is slightly higher than the old ones. They are designed with correct proportions as to bearing surfaces, wearing surfaces and range of adjustment, and are the result of months of work on the part of most of the best designers in the country, as well as parts manufacturers. The new standard screw threads which your writer passes over so airily were necessary, as there was no standard that was consistent or suited to the requirements. The new standard is the result of many conferences between the automobile engineers and such firms as Brown & Sharpe, Pratt & Whitney and several large screw and tap and die-making firms. That the standard is good, is right, and is used by many of the best car-building concerns would seem to refute the printed statement that "this is really a complication."

The standard spark plug did not create any trouble that the writer is aware of, as he has had no difficulty in getting them from any maker of plugs. It did not differ from all others, as the Autocar Company has been using this size of plug and pitch of thread for the entire term of its existence. If it is not good, what other size is better? What other size is standard? Who else has done anything to establish a standard? The other association and the S. A. E. have not been heard from.

After over two years' work in reconciling the various trade interests involved and many costly experiments, a standard Q. D. rim was adopted which will be much in evidence in 1910, as the rolls and other tools could not be made ready for the 1909 cars. A very complete set of levers has been designed by the engineers of the mechanical branch with the help and advice of the principal makers of drop forgings. These will also be out in 1910.

If you think it is an easy matter to standardize wheels and axles, just write to all the makers and see what they think of it. One hundred answers will produce one hundred designs that one hundred designers know to be the only design fit to be used under a car. The same applies to frames, springs, control parts, size of seats, etc., ad infinitum. Where is the standard carbureter? It will arrive on the same train as the standard axles and wheels, et al.

When all men look alike and act alike, then all cars will have the same method of control and not before. The mechanical branch attempted to standardize some other parts, but the difficulties to be surmounted and the conflicting opinions of what was right or wrong were so diverse that the task was abandoned as hopeless, at least for the present. The engine rating formula which you approve the branch considers as its poorest work, as it is admittedly an arbitrary makeshift.

At the time, the standardization of the bolts and nuts seemed like a "real big problem," but I see now that we are making a mountain out of a mole hill and should have started on something "real big" like the body or the engine. I am no longer connected in any way with the A. L. A. M., but like to see credit given for useful and conscientious work. E. T. BIRDSALL, M.E.

New York City.

Auto-Making Within a Hundred Miles of Philadelphia

By W. McKean White

PHILADELPHIA, April 19.—Southeastern Pennsylvania, famous as the location of many great industries, is now one of the busiest automobile manufacturing sections of the country. Within a radius of 100 miles of Philadelphia there are seven concerns of note working up to capacity to produce cars to supply orders received from all over the country. The estimated aggregate output of these concerns will be between 3,500 and 4,000 automobiles; and the hum of the machine shops and the erecting departments is indicative of the prosperous conditions generally throughout the automobile making and selling world.

Night and day work has been found necessary in some instances to keep the output approximately at the point of the demand. All types of cars are being constructed, from two to six cylinders, both for pleasure and for business purposes, and in addition to those companies confining their attention to the building of automobiles, there are numerous factories with products allied to those of the automobile, which have shared generously in the general improvement of business.

The York Motor Car Company and the Hart-Kraft Motor Company, at York; the Autocar Company, at Ardmore; the Chadwick Engineering Works, at Pottstown; the Acme Motor Car Company and the Middleby Auto Company, at Reading; and the Pennsylvania Auto Motor Works, at Bryn Mawr, are the ones which contribute to the welfare of the industry at large from the southeastern part of the Keystone State.

An important situation in Pennsylvania in connection with the building of cars which has given the manufacturers much satisfaction is the urgent demand for automobiles among farmers of that wealthy agricultural section of the State. It is no longer a strange sight to see a family of quaint-clad Mennonites, Dunkards or Ammish going to church or to town in a high-priced touring car.

With the 1909 output generally allotted, and under way through the factories, several of the Pennsylvania firms are actively laying plans for the 1910 season. One firm hopes to have its entire 1909 product completed by the middle of July, another by the middle of August, still another will have two new models for sale within the present month, while a fourth is making no plans for changing its present style and will continue to build the same cars throughout fall and winter.

THE PULLMANS PRODUCED IN YORK.

YORK, PA., April 19.—Working 22 1-2 hours of the 24, the York Motor Car Company, under the immediate direction of James A. Kline, general manager, is intent on the production of between 550 and 600 automobiles for the 1909 season. With nearly five hundred employees, an enlarged factory, new machine tools and everything favorable to securing maximum productive conditions, the firm is still behind its orders, and is at present endeavoring to overhaul the demand with an immediate supply. There are four sizes of Pullman chassis built, and these are equipped with seven types of open bodies. Only one model now can be delivered as soon as ordered, and that is the smallest one, a car of 20-horsepower. Mr. Kline, in going through the big plant, speaking of the circumstances which have required the use of the factory by night as well as day, said:

"We have greatly enlarged the plant through the addition of new buildings and the renovation of ones which were formerly occupied by the carriage works, so that we now have over 90,000 square feet of floor space. Our machine shops have been given increased facilities through the purchasing of new tools and we absolutely manufacture every part of the Pullman car, buying only the engines, aluminum and other castings and forgings, and the frames. Bodies, wheels, gears, nuts, bolts, shafts and the thousand parts that are necessary to make up a high-grade car are machined right in our own shops and nothing is bought assembled. At present we are shipping from 16 to 18 cars each week, from 45 to 50 a month being the average, so that with those already sent away, our production will total 550 or 600.

"We hope to be through with the 1909 material by the middle of July, and perhaps a little earlier, so that we can start in on cars for the following year. In fact, we expect to start on 1910 work within two weeks, and will begin to take orders for September delivery. I can assure you that there will be very little change, but there will be some few details which will be altered.

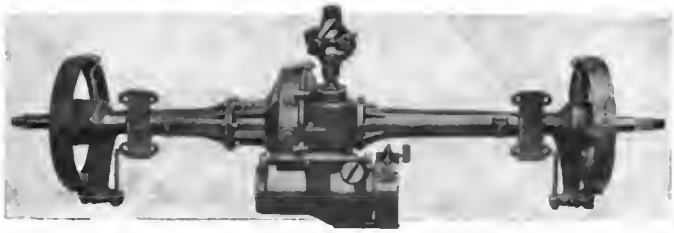
"As to contests, it is pretty hard to say just what we will do for we have been too busy to consider the matter very thoroughly. We will enter two cars in the annual endurance run of the Motor Club of Harrisburg, and I presume that we will have Pullmans in more or less track racing."

Of the four models, the medium-priced touring car with the 30-horsepower engine has proven the most popular of the line, and already 202 of the 300 to be built have been shipped. Of the 150 small cars of 20 horsepower, 70 have been sent away and on this model alone can immediate deliveries be made. About 50 four-cylinder cars of 40 horsepower will constitute the output of that size, and 36 of them are in use, while there are still 44 of the 50 six-cylinder cars to be built. Thus of the entire 550 planned in 1908, 314 have been sent away to the 37 agents.

Hart-Kraft Building Commercial Vehicles.

Under the supervision of Granville Hartman, the Hart-Kraft Motor Company is aiding in the solution of the commercial vehicle business by the production of six commercial automobiles a week, and with a standard car, a unit power plant, and

York Motor Car Company Introduces a Toy Tonneau Body for Its Four-Cylinder 40-Horsepower Chassis.



Individuality in Autocar Rear Construction.

simplified control, has found a ready market. The great difficulty of educating users of heavy horse-drawn trucks and delivery wagons has thus been obviated. A large factory has been built by the concern, and with increased facilities the rate of construction will soon be that of from 500 to 700 cars a year.

The Hart-Kraft car is equipped with a two-cylinder, double-opposed engine, developing about 12 horsepower, with a planetary transmission, giving two forward speeds and one reverse, and a double side-chain drive. The engine, transmission, differential casing and countershaft are all in a single unit, and one complete set can be substituted for another in 25 minutes. This is an important detail in commercial work where a delivery service may be handicapped if a car has to stop for a period. The testing of Hart-Kraft cars embodies some interesting features. The power unit, after being machined and assembled in the factory, is put upon a testing stand where it is first "run in" for a day with one sprocket secured so that the differential will be operated. Then it is run under its own power for a day, with its own carbureter, magneto and coil, and connected by its double side chains to a dynamo, where its power and fuel consumption is measured.

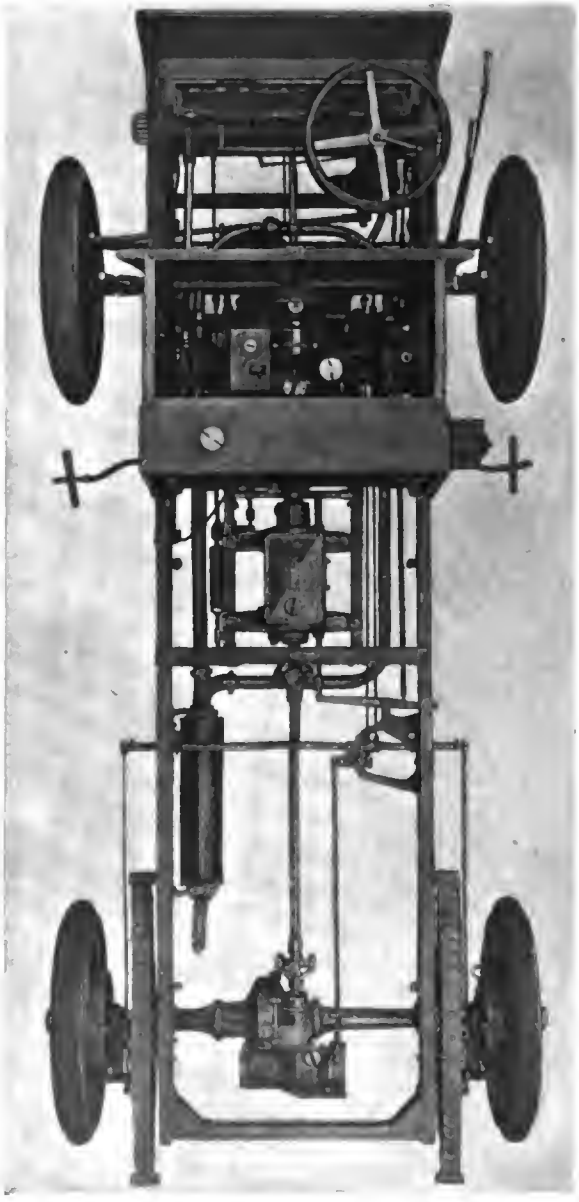
From the testing-room the power plant is moved into its chassis and the latter loaded with 600 pounds of sand. As soon as the car is taken out on the country roads it is first limbered up and then is made to climb backward up a steep hill, three-quarters of a mile long. Inasmuch as a commercial vehicle must do a great deal of reverse work in service, this test is altogether practical.

COMMERCIAL AND PLEASURE AUTOCARS.

ARDMORE, PA., April 20.—By combining the features of a commercial vehicle so that with the simple exchange of bodies it can be used as a pleasure car, the Autocar Company this year has had more business than it could accomplish with only day work in its large plant. In addition to this type of utility car, the company now has a line of four-cylinder, medium-priced touring cars which has proven equally popular. According to the president, David S. Ludlam, the outlook for the Autocar Company is one of the brightest in the life of the 12-year-old concern.

The plans for this year had called for the manufacture of 175 utility car chassis, which can be used for commercial work entirely, as delivery vehicles, taxicabs, town cars, or cabs, or with special bodies for any use, with two-cylinder engines of standard Autocar design. The reception accorded used up the first shop order, and 400 more of these machines will be started in July. This will carry the factory to the first of next year. In the meantime the entire force is concentrating its attention on the building of the four-cylinder car which made its début at the Garden show. Eighteen are constructed every week, and the entire number will be 400. It is expected that by working day and night the 475 men employed will finish these touring cars by the time the raw material for the second shop order is ready.

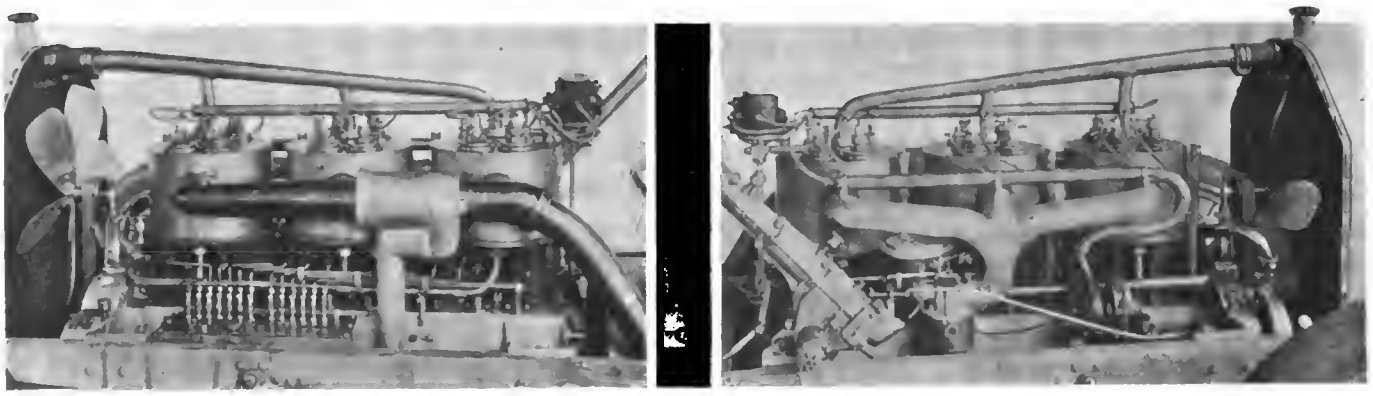
The factory of the Autocar Company has always been one of the largest in the country, but it is taxed to its utmost now. Its



Autocar Company Features a Utility Chassis.

570 machine tools are all in use, and every part of the cars is manufactured in the plant, only castings and forgings being purchased. A great deal of material for the four-cylinder cars is at present being machined, an indication of the number of cars which are constantly being sent away. The two-cylinder chassis is built in two wheelbase sizes, 85 and 97 inches, both with a carrying capacity of 2,000 pounds. The motor is more powerful than that used in the little runabouts which made the Autocar famous, 18 horsepower being developed from the 4 3-4 by 4 1-2 cylinders. Five cars with these motors were built, using surrey bodies, for experimental purposes and may at some time be added to the general line. At present only the officials of the company have them. The touring car has a motor which is rated by the A. L. A. M. at 25.6 horsepower, a three-speed transmis-

Two-Cylinder Autocar with Victoria Body.



Symmetrical Exhaust and Straightaway Intake Manifolds of the Great Chadwick Six Motor.

sion, a wheelbase of 102 inches and a five-passenger body.

That the Autocar will be well represented in racing and contests this season was shown by the statements of H. M. Coale, the sales manager, who said: "We are going into all contests in our class this summer, and perhaps in some we will compete with larger and more powerful cars. It is our expectation to put a four-cylinder touring car in the endurance run of the Motor Club of Harrisburg, one in the roadability run of the Quaker City Motor Club to Atlantic City, and perhaps we will be able to take part in the run of the latter club to Pittsburg and return. We will have two of the four-cylinder cars in the 24-hour race at Point Breeze or wherever the Quaker City Club decides to hold that event, and will try to repeat our success of last year when the Autocar won."

GREAT CHADWICK SIX BUILT AT POTTSTOWN.

POTTSTOWN, PA., April 20.—In its new, well-lighted and airy factory building the Chadwick Engineering Works is now finishing its first lot of 50 Great Chadwick Six touring cars and roadsters. With a small output of high-priced cars it can afford to send them through at a slower rate than can the makers of the lower-priced product, so that the energy of the entire force will be employed in making and erecting 115 automobiles, 90 of which will be touring cars. The remaining 25 will be roadsters of the type which attracted a great deal of attention at the shows last winter, with the gasoline tank at the rear and exhaust ports at the side, protruding through the hood.

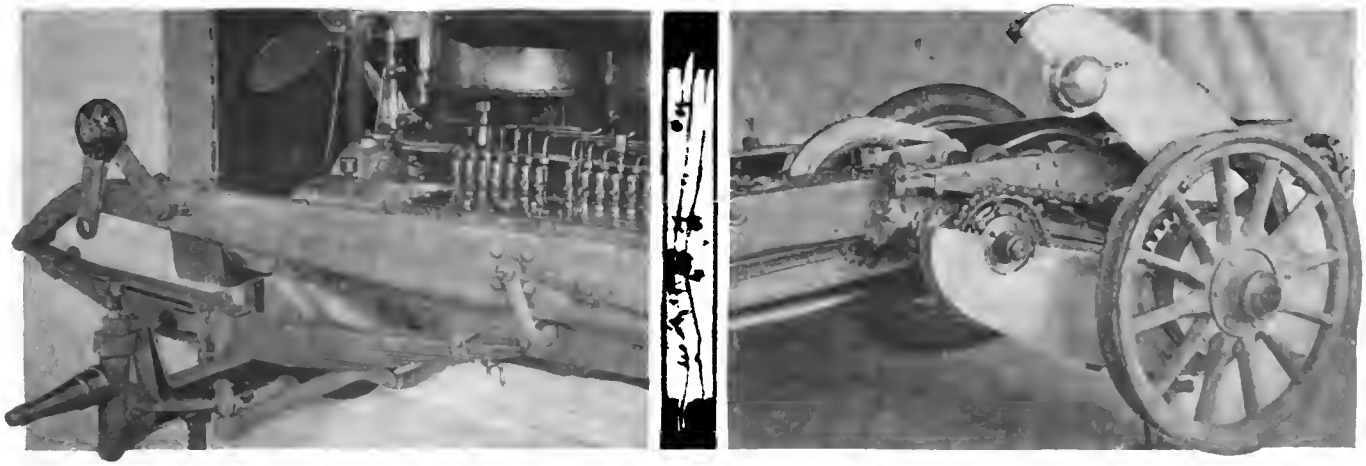
The factory building is just about a year old, and is such as to bring maximum results from the men and machines. The machine shops have already started upon the second order of another 50 cars, as the first order is finished and the last ones will have their bodies placed upon the chassis within two or three weeks. As an evidence of the number of cars which will be manufactured during the spring, L. S. Chadwick, vice-president, general manager and superintendent, points out the amount of raw material being machined or waiting to go through the finishing processes. Cylinders, crankcases, transmissions, chain cases and smaller parts are taken in the unfinished state.

Four cars a week are being finished, using both a day and night shift of employees, and this rate can be increased when necessary. At present the concern can promise deliveries in three weeks at Pottstown, and has found the spring season opening up with a bound. Within a couple of weeks the output will be pushed up to one a day, six a week, so that the output can be completed by the first of August. There has been little change contemplated for a 1910 product, inasmuch as those which have been embodied in the present car give it about 35 per cent. more power than formerly, a higher-speed motor, valves held open longer and lifted higher, and a new carbureter contributing toward this. Both Mr. Chadwick and H. B. Larzalere, the sales manager, impress upon those who talk of the Chadwick that the present stock car is a duplicate of the car which won hill-climbs so generally and made fame for itself in the Vanderbilt race last year.

Mr. Larzalere summed up the plans for the selling season and the contesting by saying: "Our agencies have been keeping us busy in trying to give them cars for early delivery, and we fully expect that the orders now in hand for spring delivery and those which will continue to come will make us work as hard as possible. We have 20 cars now waiting for their bodies, and these will all be shipped within a few days.

"Len Zengle, who has been with the Pennsylvania Auto Motor Works, will join our forces on Monday and will probably handle our cars in hill-climbs and speed contests. Just what we will enter, however, has not been decided, for we have been waiting for the various rules to be thoroughly discussed and decided upon. We would like to enter the Cobe stock-car race if the conditions are favorable, and this is true also of the Fairmount Park, the 24-hour races in New York, for we believe in racing. We will, of course, defend our record on Giant's Despair, at Wilkes-Barre, and if Chattanooga were not so far away it is probable that we would take a trial on Lookout Mountain.

"The progress in the factory has been especially pleasing to us, for we have been rushed and still able to turn out cars under



Chadwick Constructive Details Seen in Front Spring and Axle, and Chain Case Assembly.

high pressure. We are using the whole factory building: the first floor for offices and assembling, the upper ones for machining, and motor and transmission assembling, and chassis erecting, and in the basement we have our stockroom and inspectors. Every part that goes into the car is inspected by three different men before it is allowed to pass, and very often Mr. Chadwick himself takes part in this on the most essential parts."

ACME AND MIDDLEBY REPRESENT READING.

READING, PA., April 21.—This city is represented in automobile manufacturing circles by two concerns, the Acme Motor Car Company and the Middleby Auto Company, building two entirely different types of cars, the former water- and the latter air-cooled. The Acme company is engaged in turning out from two to three cars a week, its estimated product for the year, according to President H. M. Sternberg, being 125 cars. These will be divided among four chassis types, the best known of which is the six-cylinder car and a four-cylinder one of 40 horsepower. The two other models are a four-cylinder touring car or roadster of 32 horsepower and a larger "Sextuplet" of 60 horsepower.

The Acme factory, which is a large one, four stories in height, is utilized in making the cars completely under one roof, nearly the whole operation, from receiving the rough castings and other materials, to the shipping of the handsome automobiles being done by the Acme mechanics. Machine work, assembling, erecting, upholstering, radiator making, and many other details of construction being attended to by the factory itself. It is but another instance of complete manufacture and the trend away from the former practice of buying parts from various concerns and then putting them together.

As to racing, a subject in which all of the manufacturers are more than ordinarily interested, Mr. Sternberg said: "We now have 120 men working in our factory, with a shift on in the evenings, and if we keep as busy throughout the spring we will have little or no time to think about racing. We have had our racing car, the one used in the Vanderbilt and Grand Prize races, overhauled and will assemble it in about 10 days. We would like to take part in some of the events on the Indianapolis speedway and perhaps at Philadelphia, in the Fairmount Park race, for we won second place in that last year. If the conditions are such that we can enter at Chicago for the Cobe race, it is possible that our sextuplet may be purchased by a Chicago autoist and entered by him. We do not expect to take any part in endurance contests, but we may be in the 24-hour races in New York."

The Middleby company, presided over by J. Middleby, Jr., has taken hold of the old Duryea plant, and with new machine tools and certain improvements has established one of the busiest small automobile factories in the country. The history of it is interesting, as showing the public demand for a car of the type which it is producing, at the rate of six or seven a week. Mr. Middleby took hold of the buildings, equipped them with the latest machinery, turret lathes, shapers, grinders, drill presses, etc., and put the first car, a four-cylinder, air-cooled one of 25 horsepower, on the roads on August 2, 1908. No agencies were established until November, and chassis No. 213 was put upon its erecting frame to-day, with the cars turned out in numerical order. A seasonal output of about 400 automobiles has been predicted.

PENNSYLVANIA ACTIVE AT BRYN MAWR.

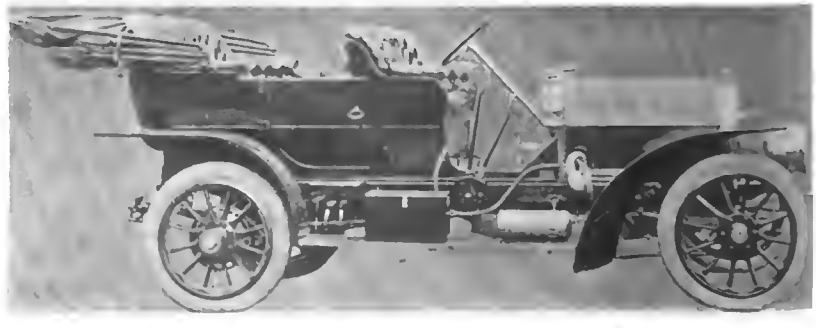
BRYN MAWR, PA., April 21.—Concrete construction in automobile factories, tending to lessen vibration and noise, is exemplified by that of the Pennsylvania Auto Motor Works, which builds the Pennsylvania cars. The quietness of the factory, while the regular work progresses, is a feature that instantly attracts attention, for as the machine tools do their work and the assemblying and finishing of cars go on, there is not the great amount of deafening noise common in other plants. The Pennsylvania company has but recently completed its new factory, and it now has about 85,000 square feet of floor space. A production of from 750 to 800 cars is planned as the total for the present season, although it is distinctly understood, by those connected with the firm, that the seasons and years are not recognized in the working of the factory. New models may be introduced at any time.

Three models are at present being constructed: a six-cylinder car of 75 horsepower; a four-cylinder car of 50 horsepower, and a four-cylinder car of 25 horsepower. The first and third are new models, while the second is the type which has been made for two years. Two new models will be turned out in about three weeks or a month, and these five constitute the complete line for the present. The new cars will be known as Models B and D6. The former will be a seven-passenger touring car with a four-cylinder engine, 4 7-8 by 5 1-4-inch cylinders, and a wheelbase of 122 inches, to sell for $3,200; while the six-cylinder car will have cylinders 4 1-4 by 4 1-4 inches in size and a wheelbase of 131 inches, to sell for $3,500.

R. Harry Croninger, the general manager, speaking of the general conditions at the plant, stated: "It is probable that by June 1 we shall have built 200 of the smallest cars, those selling for $2,100, with baby-tonneau bodies; 150 of the 50-horsepower cars, which sell for $3,000, and about 50 of the six-cylinder machines. We build our cars only to order, but the orders have recently been arriving faster than we can ship, and so at present we are 15 cars behind on our six-cylinder type and 30 on the small cars, while on the '50' we are holding our own. We have no piecework, every one of our 250 employees being on salary.

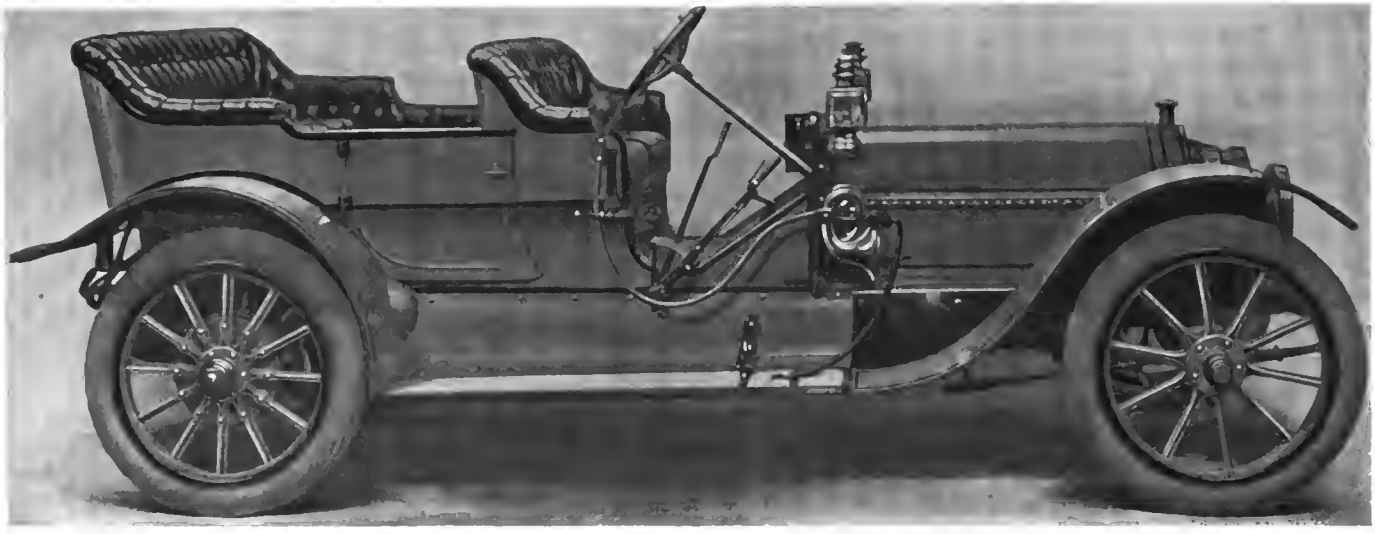
"We intend to go into all of the contests in our class, with three cars: a six and both sizes of fours. It is not planned to use either of the new models for we shall be busy constructing them to order. Gabriel, who is the foreman of the Quinby factory, and who has taken part in a number of European races, will probably handle the 75-horsepower car, but we have not decided who will drive the other two. We will not compete on circular tracks nor enter endurance runs under the present rules, but we will go into speed trials and hill-climbs. What I would like to see is a type of contest which would prove dependability, power and speed and put an end to 'axle fakirs.' I would suggest that there should be an endurance run to Wilkes-Barre, via Reading, with time schedules, intermediate controls, but not a technical examination which would penalize for little things that might happen in touring. At Wilkes-Barre I would have the cars locked up and then on the following day enter the machines in the hill-climb on Giants' Despair according to their various classes and make them climb with the same load carried on the run from Philadelphia. On the third day, the machines would be run to Canandensis, in the Pocono Mountains, where there would be a speed trial, again entering the cars in their classes.

The Smallest Pennsylvania, 25-Horsepower.



Another of the Pennsylvania Family—50-Horsepower.

About the Matheson Six-Cylinder



Latest Creation of the Matheson Automobile Company—A Light Six-Cylinder Touring Car of 50-Horsepower.

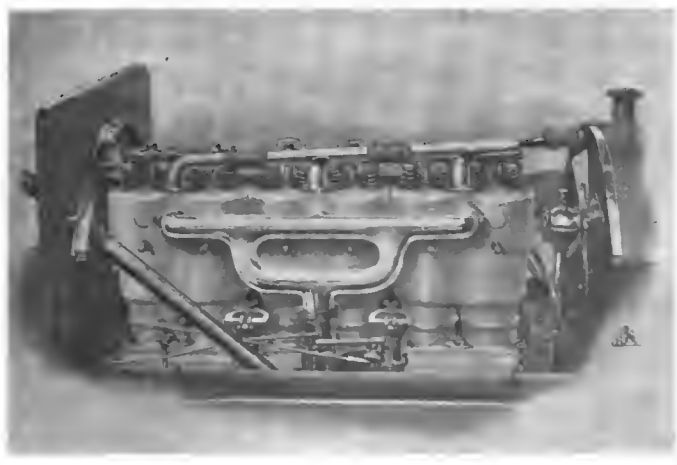
NEW YORK, April 19.—Matheson "Light Six" is here, with the consequent result that the selling headquarters of the Matheson Automobile Company, 1886-1888 Broadway, has been one of the busiest places in the automobile district during the past few days. The car which has arrived is the first to be delivered since the type made its début at the shows. Two models were then announced to come from the Wilkes-Barre factory for the 1909 season. The "fours" were then deliverable, and now the "sixes" are being made and shipped in considerable numbers.

A feature construction has been assiduously avoided in the design of the six, although it differs materially from the type of the present four, or of the six-cylinder car which was made two years ago. The changes have been made chiefly in motor- and transmission-gear construction, with their various appliances, but the workmanship is of the same standard and the experimental cars so thoroughly tried on the northeastern Pennsylvania mountains that the deep confidence of the Matheson company is reposed in the latest production of their factory.

Description of the Engine.—The notable feature of the six-cylinder engine is in its valve action, which has been materially changed from previous practice, although in nowise detracting from the latter. The valves, all in the head and at the right side, are operated through depression from overhead beams, which, in turn, are raised by lifters from a single camshaft in the crankcase on the left side. The valves, 2 3-8 inches in diameter, are all interchangeable, electrically welded to their stems, and have flat faces. The lifter rods have screw adjustments.

The six cylinders are cast in sets, three dual units to each engine, with a bore of 4 1-2 inches and a stroke of 5, rated by the Matheson company at 50 horsepower. They are enameled to give the same clean appearance, as are all cylinders of this make, with the intake manifold on the right side and exhaust on the left. The carbureter is of special design, of the multiple-jet type, which has proven successful on previous models, with a control both from the top of the steering column and from a foot throttle. The crankshaft is offset 3-4 of an inch, running on four bearings, the front one being an annular Hess-Bright ball bearing and the others of plain phosphor bronze.

Lubrication System.—Special attention has been given to the lubrication system for the motor, the rear construction, of course, taking care of itself. Splash in the crankcase is supplemented by a three-lead Lavigne mechanical oiler, situated on the left side, just behind the first crankcase arm, and driven from enclosed gears. The oiler, water pump and magneto are placed in the order named on the left side, and a single shaft with intermediate couplings drives them 1 1-2 times the motor speed. Each



Intake Side of New Motor Showing Carbureter.

Rear Construction with Transmission Uncovered.

of the oiler-leads branch into pipes to the various cylinders or bearings; one lead forcing lubricant to the three plain crankshaft bearings; one branching into six, to supply oil to grooves in each of the cylinders, and the third has six oil pipes arranged to drip upon the lower ends of the connecting rods as they move.

High-Tension Ignition Used.—An innovation for Matheson cars is the use of high-tension, jump-spark ignition, with plugs placed in the right side of the cylinder castings and obtaining current from a Bosch magneto.

A standard water-cooling system is embodied, with a centrifugal pump, cellular radiator and gear-driven aluminum fan. The radiator is the same shape as that characteristic of the Matheson, of ample size, with large piping to the tops of the cylinders and to the pump. The latter has an aluminum casing, bronze impeller and steel shaft, driven, as stated above, from the oiler-pump-magneto shaft, and forcing its water into the jackets on the left side at the bottom. The fan, which consists of six aluminum arms riveted to the hub casting, is 16 inches in diameter, and is driven through bevel gears from the crankshaft with a 2 to 1 reduction. To take up any sudden motion on the part of the engine a spiral-jaw clutch is interposed.

An 18-inch flywheel, mounted on the rear of the crankshaft, contains the multiple-disk clutch in an oil-tight casing. There are 51 flat steel disks in the assembly, the rings have alternately eight notches and eight lugs, forced together by a spring which gives a load of 140 pounds. A tubular rocker sleeve is used to connect with the clutch-foot-pedal, and the arms are long enough to give an easy and delicate action. The entire front of the chassis, from the radiator to the flywheel, is protected from road dirt by the extension of the motor base to the side of the frame.

Transmission Integral with Rear Construction.—Shaft drive, with a three-forward and one reverse speed, selective sliding-gear transmission, located in a crucible-steel casting together with the bevel driving gear and the differential, and a full floating rear axle constitute the transmission construction. Thus there is nothing between the clutch and the rear axle, except the propeller shaft, which is of solid steel, 1 5-8 inches in diameter, squared at both ends. This shaft runs in a casting, which is at once the strut and the torsion tube, performing the functions of the latter through a globe-end fastened to frame cross-girt. Deflections are compensated for by a suitable device. The transmission shafts run on sets of ball bearings, with thrust bearings located advantageously. The two sliding gears are made of chrome nickel steel and all other gears are of nickel steel, oil tempered, with 7-8 of an inch face. On high speed the drive is direct to the bevel pinion and gear, the whole construction of which can be readily reached for inspection by removing the cover. The differential is of the bevel-gear type. The drive from the bevel-gear housing to the wheels is through floating live axles, made of nickel steel, of 1 1-4 inch diameter, with squared ends, and oil tempered. Six-tooth nickel-steel clutches form the connection between the shafts and the wheel hubs. The whole rear construction of the new cars is of special Matheson make—no means was spared to test it in preliminary work and it showed its worth and was adopted.

The front axle is by Timken, I-section, a single drop-forging without welds, with adjustable roller bearings. Half-elliptic springs are employed in front and three-quarter-elliptic in the rear, the former being 34 inches long, with seven leaves, joined to the sideframe eyes in front and linked at the rear; the latter springs are extra long and strong, to insure ease in riding, the lower member having eight leaves and is 40 inches long, linked to the chassis frame, and the upper member also has eight leaves, 21 1-2 inches long, from the scroll-spring eye at the rear to a chassis bracket in front. Oil holes and oil screws are provided.

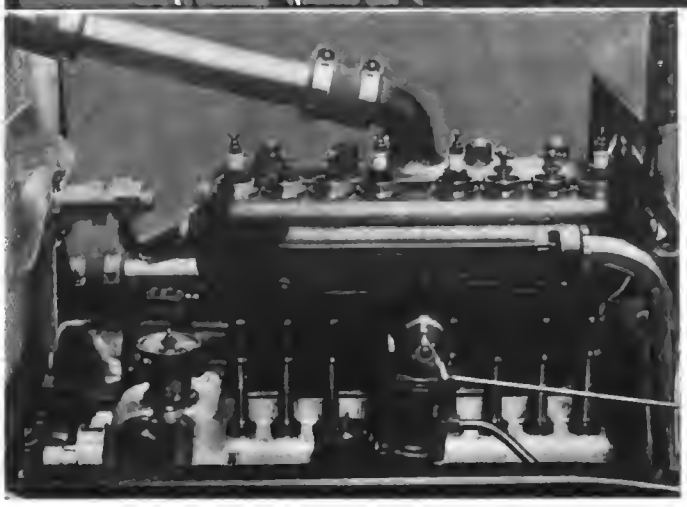
Minute Attention to Important Details.—Brakes, control mechanism, steering and the other parts of automobiles which must be given the most accurate consideration in designing and building have been thoroughly attended to in the Matheson cars in general and in this model in particular. There are two sets of brakes, both operating on the rear wheels, one set being expanding and the other contracting. The drum is 2 inches wide and 14 inches in outside diameter. The internal set is applied by the the right foot-pedal and the other by a side lever, but between these and the brakes themselves are interposed brake-eveners. Within the drums are located the hold-back pawl and ratchet controlled by a foot-pedal on the toe-board.

An irreversible steering action, through a hardened worm and sector, is obtained and the steering cross-rod placed behind the front axle. The knuckles are all drop forgings, fitted with grease and oil cups. The spark and throttle levers are situated upon the top of the steering post and are stationary.

The new "six" is fitted with a five-passenger body which much resembles the toy tonneau type, because of its low, rakish appearance, and in color and general lines follows standard Matheson practice. The upholstering is of high-grade leather, with tufted seats and backs; the fenders and running board are enclosed; the gasoline tank is fastened to the pressed-steel frame at the rear, and the wheels are 36 inches in diameter, using 4-inch tires.

Control Mechanism and Unobstructed Dash.

A Franco-British Newcomer



The Motor Shows Clean and Natty Proportions.

LONDON, April 10.—At the Manchester show a number of cars were shown for the first time, and none attracted more attention than the F. L., which, although the product of a famous French house and built complete in the shops across the Channel, R. M. Wright & Co. have taken the exclusive rights to it, and they propose to sell only in England. This makes the car practically a British product.

Placed alongside of other cars, the feature which is most apparent is the neat yet extremely simple lines of the whole chassis. Beginning with the motor and carrying right through to the back axle and rear construction, every piece shows this tendency toward simplification. Moreover, ease of adjustment and facility of dismantling have been most carefully kept in view, so that for such service as taxicabs, the whole construction is ideal, as the removal of any part is a matter of minutes.

Engine Has a Straightforward Appearance.—As the view of the left or valve side of the motor shows, the cylinders are cast *en bloc*. The exhaust is not cast integral, but is a simple ribbed casting attached by three bolts to the machined face of the cylinder. The valves are grouped on the one side, with the carbureter placed low down on that side. The inlet pipe is integral with the exhaust, and so carefully worked out that at first glance, there does not appear to be any inlet. The carbureter is attached to this in such a manner that it can be removed in a minute or can be rotated out of the way without disconnecting it. Double ignition is fitted with the timer located at the left, forward, and driven from the camshaft. The high-tension magneto is placed on the other side, at right angles to the motor, and is driven from the crankshaft. It is very accessible, and may be removed in less than a minute without disturbing anything.

The engine is of the four-cylinder type, with 80 mm. (3.15") bore and 100 mm. (3.94") stroke. The rating is 12-16, the latter being the R. A. C. rating for this bore. The under portion of the crank chamber, flywheel pit and lower half of the gearbox is in one aluminum casting, which forms its own underpan, and is carried directly on the main frame side members. Cooling is by thermosiphon, the outlet from engine to the top of the radiator being a single straight pipe of large diameter. The return is lower down on the other side, and is also of large diameter and free from bends, only one being necessary. The cooling is assisted by a large sized fan, belt driven from the crankshaft, and hung from the cylinder block on an I-section bracket.

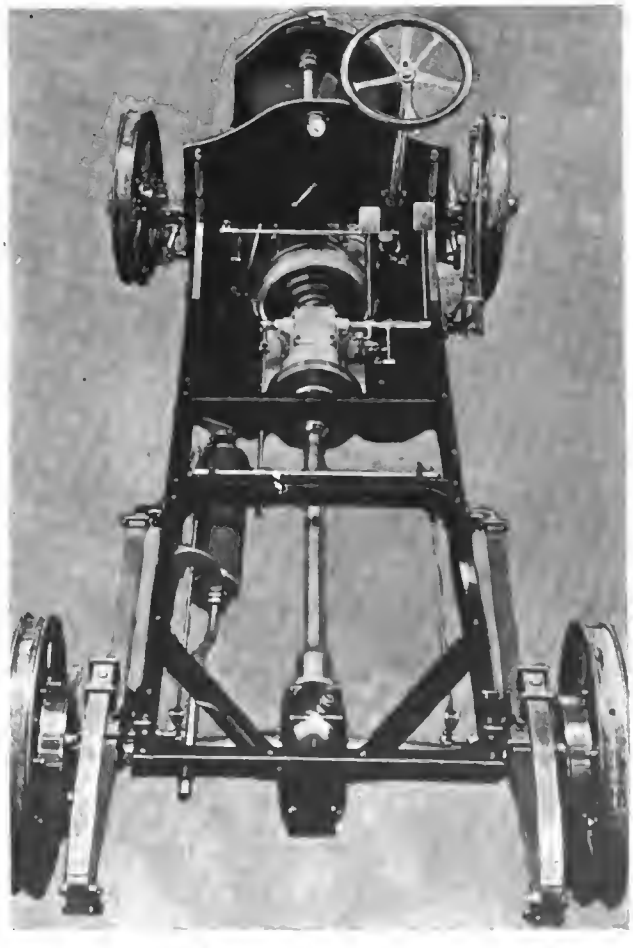
Lubrication Well Cared For.—The engine is lubricated by the pressure system, the oil being forced by a gear-driven pump through the drilled shaft and to the reservoir on the dash, from whence it flows by gravity to all other places. This reservoir is placed on the engine side of the dash, so as to conform to the modern desire for a clean dash on the driver's side. A dial indicator shows the amount of lubricant on hand.

The transmission gives three speeds and reverse, with the usual direct drive on the high. From this the drive is by means of a cardan shaft enclosed in a very large tube and turning on ball bearings. The rear wheels carry a pair of brakes, enclosed and of the internal expanding type. These and the footbrake on the mainshaft are operated by adjustable means, all of the pedals being quickly changed, while the hand levers can also be changed to suit the operator's physique.

One-Lever Control Is Featured.—The steering-post control of the engine follows the practice inaugurated by Renault in the use of one lever. The spark advance is fixed and the single lever provided works the throttle. The steering wheel is of the four-segment design, with an original method of assembling.

The frame is of pressed steel, and has a liberal section. There are two bends, one at the dash to allow of a large steering lock and to dispense with a sub-frame. The other is just forward of the rear axle, and is designed to lower the center of gravity. The springs follow usual practice, with three-quarter elliptics in the rear. The wheels are large and fitted with good-sized tires.

The chassis form, the F. L. sells at £285 ($1,400), and with the body fitted the price is £350 ($1,700), so that it comes in the so-called popular class of four-cylinder cars.



View of the Chassis and Rear Construction.

HOW STEVENS-DURYEA USES TEST-BLOCK ENGINES

By JOHN W. FEW, Jr.

CHICOPEE FALLS, MASS., April 19.—Most interesting is the practical and economical use of the engines placed on the testing block at the Stevens-Duryea plant, and it also illustrates how the cost of a car can be reduced through improved equipment and factory organization. The well-equipped factory to-day cannot only do better work than formerly, but it can do the same work at much less cost.

Two years ago the writer was much interested in seeing the engines on the testing block churn up great quantities of water in a huge tank to show "what they could do." The power was there; but it was all wasted. The water was simply being used as a resistance. Now all is changed. There is the same roar of turning machinery as the fifteen or more engines strain at their blocks, but the energy, instead of being dissipated uselessly in water, is conserved by dynamos and used to drive the machinery in the building. Each engine is placed on a separate frame and attached to a Westinghouse direct-current motor of 17 kilowatts capacity, but capable of a considerable overload. When the engine is first put on the stand it is run in by the motor. After a complete limbering up the engine under test is required to drive the motor for a number of hours, developing about 38 horsepower. The engine is then taken down; that is, the main bearings are all taken apart and examined to see if any wear has developed, and every moving part is minutely examined before reassembling. After this the engine must make a continuous run of 10 hours, driving the motor and must produce 38 horsepower or over all the time. Located above the testing frames is a large switchboard, the gauges of which are numbered to correspond to the numbers on each frame. At a glance the output of each machine can be seen.

Great care has been exercised that in the operation of the engines conditions shall approximate those obtained in actual usage. Gasoline, which is stored in a 400-gallon tank, is delivered to the engine with the same flow and pressure that exists in the complete machine. This is secured by the use of an auxiliary tank containing two gallons. By the use of a ball valve the flow is regulated and the carbureter works under the same condition as in actual service. The cooling system has been worked out with the same care. While the radiator is missing, a large tank is connected up to the engine and insures a sufficient cooling medium. An auxiliary pump is interposed in the system to insure that the head of water and pressure is the same as when the motor is on the road. The current generated by the engine is used in the factory and the output of the fifteen or more engines, each producing 38 horsepower, is no small item of economy. A 75-horsepower generator, with suitable governor, is also connected up in series, so that when a number of engines are being changed at the same time and the output consequently diminished it can take up the load and the work goes merrily on. The efficiency of the system in furnishing power was put to a test not long ago. The large generator broke down and for several days was out of commission. By extra efforts on the part of the testing force to keep the 18 stands full, the machines under test furnished sufficient power to run the plant without one instant of stoppage or the secession of one machine unnecessarily. Thus, the utility of this apparently useless work was proved to the satisfaction of every one concerned.

Although the engines get such a careful test on the blocks they are further tested on the road. After being fitted to a chassis they are driven for three or four hours, then taken apart and once more examined for wear, valves again ground and then once more are taken on the road and tuned up by the tester. If the engine performs to his satisfaction he turns it over to the head tester, who once again takes the car on the road and makes it do "stunts." It must throttle down to a snail's pace on the high, pick up on the spark, and take certain hills on direct drive. Out of respect to the law in Massachusetts, nothing will be said as to the speed required. After this the car receives the regular body and equipment and is again taken on the road for a short run. This is to determine that everything is right. While some of these tests appear to be useless, it is only an indication of the painstaking care practised at the factory to insure a perfect car.

Stevens-Duryea Testing Room—Six-Cylinder Engines in Foreground, Fours in Rear—Electrical Gauges and Testing Apparatus Overhead.

What One Pennsylvania Club is Doing for Roads

LANCASTER, PA., April 19.—Depending upon the newspapers of the county and the spirited enthusiasm of its members, the Lancaster Automobile Club has inaugurated a system of good roads improvement that bids fair to eclipse the efforts of any other automobile club up to date. The most striking thing about the whole movement is that it is so practical and is meeting with the hearty cooperation of the farmer element. Lancaster county has over 1,000 miles of public highway and is divided into 40 townships and nearly that many cities and boroughs. Each of these localities is presided over by its road officials. Scattered throughout the county are 30 newspapers and the club's plan is carried out as follows:

The consent of each of the road officials is gained to permit a one-mile stretch of dirt roadway to be dragged by a King Split-Log road drag for a period of 20 hours of labor all told, the dragging being done after each rain by farmers who live at convenient localities. The club supplies the drag, pays the farmer who drags the road and agrees to make good by a $500 bond if necessary that no damage will be done to the roadway. At each section of the county a newspaper is given the credit of conducting the experiment and the news columns of the nearest paper are kept alive with frequent reports regarding the condition of the road from time to time, demonstrations held upon it, officials present, comparisons with stretches of road not dragged, etc.

Newspaper correspondence is solicited from the farmers living in the neighborhood of the demonstration and they are afforded every opportunity to drive over the newly dragged road and examine its condition.

One board of supervisors from the township of East Lampeter were so set against this method of road improvement at first that they put the matter into the hands of their lawyers, who notified the club that if any such means of working their township roadways was adopted they would prosecute those who might do the work. By dint of tact and perseverance on the part of the good-roads committee and the club's solicitor, this board of objecting supervisors finally permitted the club to carry on its work. Over 2,000 four-page pamphlets describing in detail the method of constructing a road drag have been distributed to the farmers. The county of Lancaster is becoming a beehive of good-roads industry, and the progressive plan of the automobile club gives every evidence of being the right remedy for *"Good Roads Now,"* which is the campaign slogan of the autoists.

GOOD ROADS TALK FREQUENT NOWADAYS IN CONGRESS

WASHINGTON, D. C., April 19.—The good roads movement has no greater advocate in Congress than Representative William Sulzer, of New York. During the past week he delivered a strong speech on the subject, stating among other things that national aid for good roads is demanded by the people, and the question will grow more and more important as the seasons come and go until the demands of the people are granted by the national government. The following excerpts from Mr. Sulzer's able address are of pertinent interest:

"Good roads mean progress and prosperity, a benefit to the people who live in the cities, an advantage to the people who live in the country, and it will help every section of our vast domain. Good roads, like good streets, make habitation among them most desirable; they enhance the value of farm lands, facilitate transportation, and add untold wealth to the country. Good roads have a money value far beyond our ordinary conception. Bad roads constitute our greatest drawback to internal development.

"The direct connection between good roads and the value of farm lands is shown in a striking manner by the United States Department of Agriculture. The returns received by the department from various States show that in nearly every case the States having the highest percentage of improved roads have the largest population per mile of road, thus showing that better roads are a powerful factor in encouraging the settlement of unused lands, especially in sparsely populated sections of the country. A comparison of the percentage of the improved roads of the various States shows that the average percentage of the improved roads in all States where farm land is worth less than $20 an acre is only 1.8 per cent.; whereas in the States where the acreage value is more than $20, improved roads constitute an average of 9 per cent. of the total mileage.

"The farsighted wisdom of Julius Cæsar built from the Imperial exchequer the magnificent roads that led in all directions to eternal Rome. The great Napoleon—Cæsar like—built the roads of France that center in Paris from the general funds of the government; and these French roads have done more than any other single agency to encourage the thrift and increase the industry of the people of France. Cæsar and Napoleon were the great road builders of ancient and modern times, and their foresight and their judgment and their work demonstrated the beneficient results that follow like the night the day the building of great governmental highways."

TOLL ROAD'S CONDITION PROTESTED.

WILMINGTON, DEL., April 19.—Alleging that the Philadelphia and Wilmington turnpike is in bad condition, some of the users of the road have taken steps to try to have it improved or the taking of toll thereon stopped. A petition has been drawn up by Robert L. Baldwin, who uses the road, and it has been signed by a number of others. An inquiry will follow, and that will determine the petitioners' rights.

What the Clubs are Doing These Days

MARYLAND WILL WELCOME PENNSYLVANIANS.

BALTIMORE, April 19.—These are busy days for the members of the Automobile Club of Maryland. Their request to Secretary of State Winslow Williams that the members of the Harrisburg Automobile Club who are to participate in the endurance run from Harrisburg to Scranton, through sections of Maryland, be permitted to operate their machines in this State without having to procure a Maryland license, has been granted The certificate of concession issued by the Secretary of State stipulates, however, that the visiting autoists will be subjected to all other State laws and regulations.

Members of the local club are planning to entertain the visitors during their stay in Baltimore. A delegation will meet the Harrisburg motorists at Relay, on their way from Washington to Baltimore, and escort both the pilot and chairman cars to this city. The checking station will be at the Automobile Club of Maryland quarters.

Two more councils of the State Association of Motorists, the organization which intends to look after proper and just legislation for Maryland owners, were organized during the week. These were the Salisbury and Elkton councils, the latter being in the home city of Governor Crothers, who favors the Swann Bill, which caused such a stir among owners until some of its original provisions were modified.

A. C. OF HARTFORD ELECTS NEW OFFICERS.

HARTFORD, CONN., April 19.—At the annual meeting of the Automobile Club of Hartford, held last Wednesday evening at the headquarters in the Allyn House, General Wallace T. Fenn was elected president; Thomas W. Russell, vice-president; C. D. Alton, Jr., was re-elected treasurer, and Arthur G. Hinckley was elected secretary. The election of the new officers puts into effect the recommendation of the committee on the expansion of the club at the meeting on March 26, that the officers be automobile owners, and not allied with the trade or industry in any professional capacity.

The committee on new quarters recommended a location on the ground floor of the Allyn House, to take the place of the present quarters on the second floor. The membership report showed a present membership of 318, one member having been dismissed for violation of the automobile law. The annual dues for old members have been increased from $5 to $10, and for new members to $15. Following the close of the regular order of business, former President J. Howard Morse, who has just returned from a two years' stay abroad, gave an interesting talk on his automobiling experiences in Africa.

WORCESTER'S DEAD HORSE CLIMB JUNE 17.

WORCESTER, MASS., April 17.—The board of governors of the Worcester Automobile Club has decided to hold the annual hill climb on Dead Horse Hill, Saturday, June 17. This comes on a date when there is no other event of similar character scheduled in New England, and it is expected that the entries will be exceptionally large, as last year's event was an unqualified success. The committee consists of President John P. Coghlin, Daniel F. Gay and Albert H. Inman.

For several weeks the club has been considering an independent hill for the climb. It is realized that with the high-power cars this year Dead Horse is not as stiff a proposition as is desired, and it was thought that if a private hill could be secured it could be used as a recognized hill on which to hold tests, there being no place in New England where a car can be tested without violation of the speed laws. To build a hill a mile in length would cost about $15,000. and the club could not get such a proposition under way in time for a climb this year. It was finally decided to utilize Dead Horse Hill for this year's contest.

MINNEAPOLIS CLUB HAS 804 MEMBERS.

MINNEAPOLIS, MINN., April 19.—Horace Lowry was unanimously re-elected president of the Minneapolis Automobile Club at the annual meeting. The other officers named were: First vice-president, C. F. Haglin; second vice-president, S. M. Colburn; secretary (re-elected), G. H. Seeley; treasurer (re-elected), J. H. Riheldaffer. Of 14 candidates for the board of directors, Dr. C. E. Dutton, G. H. Seeley, H. E. Pence and Frank Cook were elected. President Lowry announced the appointment of the chairmen of committees as: House, H. E. Pence; good roads, G. A. Will; sign posting, Harold Vorce; legislation, Dr. C. H. Kohler; membership, E. L. Brown; tours and contests, Dr. C. E. Dutton.

During the past year 326 new members have been received into the organization, bringing the total to 804; and in other lines the club has been similarly successful.

LOUISVILLE CLUB HAS DOUBLED MEMBERSHIP.

LOUISVILLE, KY., April 19.—Improvement in country roads and the generous erection of signposts in Jefferson county were advocated at the annual banquet and meeting of the Louisville Automobile Club. The new officers are: President, J. T. Ross; first vice-president, H. E. Tuley; second vice-president, R. E. Morris; secretary, E. J. Straus; treasurer, W. I. Kohn; directors to the State association, G. S. Barnett, Prince Wells, Lee Miles, Dr. R. L. Ireland, J. M. Chatterson.

The willingness of the municipal park board to an increase of the speed limit from 12 to 15 miles an hour was signified, and also its intention to construct stone bridges in Cherokee Park. Committees were appointed by the newly elected president to take up the matter of road improvement and signposting. The club now has a total membership of 205, double the number on the lists a year ago.

GENEVA (N. Y.) CLUB WILL HAVE SUMMER RUN.

GENEVA, N. Y., April 19.—At a meeting of the Geneva Automobile Club, held recently, the resignation of President Herendeen, who is going to Europe, was accepted, and the following members elected to office for the ensuing year: President, W. L. Fay; vice-president, E. S. Sigler; secretary and treasurer, C. W. Fairfax; executive committee, G. M. B. Hawley, Dr. W. H. Jordan, H. L. Rose. Good roads and the regulations of speed were subjects which were discussed and plans for the summer run were also taken under consideration.

SPRING ACTIVITY OF CANADIAN AUTOISTS.

MONTREAL, CAN., April 19.—With the opening of the spring touring season, the Automobile Club of Canada has outlined a number of lines of activity. One of these deals with the dust nuisance, and together with the municipalities between this city and St. Anne's on the lake shore, it has arranged to oil roads most used by autoists. In connection with road work, it has

been planned to post signs between Montreal and Rouse's Point, thus forming marked touring routes with those coming from the United States. Arrangements have not been fully completed for the three days' race meet to be held on the Blue Bonnets track. It is expected, however, that this will be made a very important event and will be entered by a number of prominent drivers.

JAMESTOWN (N. Y.) CLUB PLANS MANY EVENTS.

JAMESTOWN, N. Y., April 19.—These officers for the coming year were chosen by the Jamestown Automobile Club at its annual meeting: President, W. J. Maddox; vice-president, Fletcher Goodwill; secretary, Louis C. Breed; treasurer, B. D. Phillips; trustees, Peter H. Hoyt, S. B. Broadhead, Oscar Stranburg, Dr. W. E. Goucher, H. W. Fenton, W. A. Marson, J. H. Wright, F. O. Anderson, C. O. Pickard, D. H. Grandin, F. P. Hall, W. W. Hunt.

An effort is being made to increase the membership, and plans have been made for a series of events for the summer, including a parade at an early date, races in July, club runs to places of interest and improvements in the neighboring roads.

FIRST ANNUAL MEETING OF NEW HAVEN CLUB.

NEW HAVEN, CONN., April 19.—The New Haven Automobile Club celebrated its first annual meeting and birthday at Savin Rock, last Wednesday evening, combining the election of officers with a smoker and Dutch supper. Nearly all of the 200 members attended. The officers chosen are: President, Thomas G. Bennett, re-elected; vice-president, J. P. Goodhart; secretary, W. T. Dill; treasurer, C. E. Thompson; board of governors: T. G. Bennett, J. P. Goodhart, W. T. Dill, F. G. P. Barnes, C. M. Robinson, P. S. Thompson, A. L. Chamberlain. Chairman of committees: Legal, C. M. Robinson; membership, P. S. Thompson; contest, W. A. Maynard; good roads, F. G. P. Barnes; sign posts, A. L. Chamberlain.

A PICTURESQUE PENNSYLVANIA ROUTE.

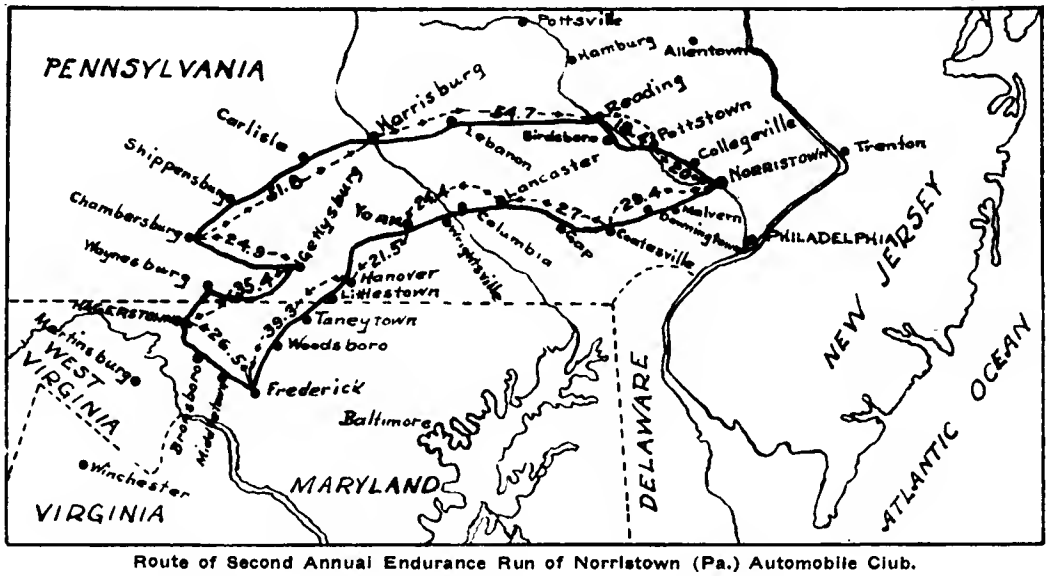
NORRISTOWN, PA., April 19.—Passing through the most prosperous, as well as the most historic, part of the State of Pennsylvania, the route chosen for the second annual endurance run of the Norristown Automobile Club has elicited a widespread interest. Members of the local organization and automobilists from many parts of the surrounding country have decided to join with the contest simply because of the pictorial nature of the country to be covered, as aside from the contesting spirit. Four hundred miles of highway will be traveled in the run of two days' duration to Hagerstown, Md., and return, on May 18 and 19.

Starting from this city, the tourists will cross the Schuylkill River, to the Lancaster pike, and turn westward toward Downingtown, a portion of the Chester valley which is bordered on the south by the Hundred-Mile Woods, and on the north by the Valley Forge hills. The famous old road is followed through Coatesville, skirting the Welsh mountains, in which some beautiful views of the prosperous Lancaster county will be gained. The general direction of the proposed State highway from Philadelphia to Pittsburg is taken, and most of the distance is over some of the roads which are included in the plans. At Lancaster the contestants will continue due west to Columbia, where they will cross the mile-and-a-quarter-long bridge over the Susquehanna River. A rich farming country is traversed to and beyond York, and the Blue Ridge mountains will be seen in the distance. The first reminders of the historical ground will be seen at Hanover, in the center of which place is a large monument to the soldiers who fell at Gettysburg, and shortly after passing through Littlestown the Mason and Dixon line is crossed, into Frederick county, Maryland.

In Frederick, the site of Barbara Frietchie's house will be passed, and the route takes a slight northerly turn, crossing the Catoctin mountains at Braddock Heights. The views will be well worth the trip, for a descent is made, into the fertile Middletown valley, over a natural switchback road, with the Blue mountains but a few miles away. A climb of three and a half miles to the top of Bolivar mountain, close to the battlefield of South Mountain, will furnish a real test for the automobiles. Historic spots are everywhere made known by the Government signs, Harper's Ferry to the south, and Antietam to the west. Hagerstown, the night stop, has ample facilities.

The homeward-bound trip is commenced in a northeastern direction, soon the Mason and Dixon line is re-crossed, and Waynesboro is the first place of size entered. Another climb of three and a half miles to the summit of the Blue Ridge, through Penn Mawr, by the Blue Ridge Mountain House and Chariman, will reveal to those who have never taken the trip some of the most splendid views in the East, the valleys on both sides being easily seen just at the summit. The descent will be made through Monterey Gap, over the road which General Lee used in retreating after the battle of Gettysburg. Still proceeding in an easterly direction, Jack's mountain, a spur of the general system, is crossed, and Gettysburg reached. This will, of course, be exceedingly interesting, and perhaps more so when it is considered that the road taken toward Chambersburg, crossing the mountains north of Cashtown, is the same one which General Lee took in approaching the crucial encounter with Meade. As a contrast to mountain climbing, the run up the Cumberland valley will be a particularly pleasing one, as it always is to autoists who have just come across the Alleghanies.

At Harrisburg the turn to the East is made, via Reading, over Mount Neversink, and through Birdsboro and Pottstown, to the finish at Norristown. The distance on the first day is 190 miles, and on the second 210, so that even though going through a picturesque and interesting country, the event is not without its qualifications as a competition and an endurance tournament. Already a large number of entries have been assured of the Philadelphia automobile trade. The Oldsmobile "six" with its 42-inch wheels, and the American Traveller with 40-inch wheels will be among the contestants.



Route of Second Annual Endurance Run of Norristown (Pa.) Automobile Club.

NEW YORK PREPARES FOR WEEK OF FESTIVITIES

ENTHUSIASM for the second annual carnival of the New York Automobile Trade Association has been bubbling forth from the concerns in the automobile business of the metropolis during the present week, in preparation for the festivities of the next. Banners, bunting, and other decorative ornaments have begun to appear on the buildings along and just off of Broadway, while the interiors have been appropriately arranged for the celebration of the opening of the spring touring and selling season. A hill climb, a series of speed trials, an efficiency contest, a demonstration of the feasibility of automobiles in conveying troops, and a mammoth parade are the features in which the automobiles will be the centers of interest. A dinner dance and a smoker will furnish evening social entertainment and a souvenir day will supply some surprise in novelties which will be given to customers and friends of the dealers. So successful was the carnival last year that this one has been anticipated and some elaborate preliminary work done for it.

Opening on next Monday, there will be a hill climb on the Fort George hill which, in point of entries assured, will surpass any yet held. Price classification by the A. A. A. standard has been adopted, and there will be eleven events, seven for gasoline cars only, one for steam and one for electric cars only, and free-for-alls. Entry blanks for these have been issued.

Tuesday straightaway speed trials on Hillside avenue, Jamaica, L. I., will be run, over the same course used in races last Spring.

Souvenir day will hold the attention on Wednesday, with a dinner dance in the evening at the Hotel Marseille.

Inability to get a track in good condition has prevented the original plan of a track race and games for Thursday, and instead it has been decided to call this "Military" day. The remarkable demonstration held recently in England of the manner in which soldiers can be quickly mobilized and transported some distance will be duplicated here, four or five hundred members of the ninth regiment of the militia, fully equipped for service, being the soldiers in the case. They will be picked up at their armory and carried to some suburban place for luncheon, and brought back late in the afternoon.

One of the most interesting events announced will be the feature of Friday, that of a one gallon efficiency contest, planned on much the same lines as the one held several years ago. The contestants will not know the route to be taken until just before the start; they will be given a single gallon of gasoline, and will run as far as possible, using special tanks if desired, in order to get every drop of gasoline before stopping. To put all upon an equal basis regarding size and power, it has been decided that the score of the cars shall be obtained by multiplying the distance traveled by the weight of the car and its occupants. The price classification will also be in effect and there will be an observer on each car. Distance will be measured by odometers, unless a specially measured suburban course can be obtained.

Decorative effects may be given full reign in the carnival parade, an event in which hundreds of automobiles are expected to take part, held this year in the afternoon instead of the evening. There will be sections for beautifully hedecked cars, for grotesquely finished ones, for commercial cars, floats, and for regularly equipped cars, so that all kinds, types, and sizes may take part. Generous prizes, both cash and plate, have been announced for all the competitive events of the week. Manufacturers, dealers and branch managers have entered heartily into the spirit of the affair, and the size of the parade may be surmised from the fact that the Maxwell Company alone has made arrangements for 150 cars; another concern that had previously entered 30 raised this to 50, and others are expecting to do likewise. Added to the trade division will be the great number of private owners who have made extensive preparations.

The following is the list of events scheduled:

Monday, April 26.—Fort George hill climb. Eleven events.

Tuesday, April 27.—Straightaway speed trials, Hillside avenue, Jamaica, L. I.

Wednesday, April 28.—Souvenir day on Automobile Row. Dinner dance at Hotel Marseille, Broadway and One Hundred and Third street.

Thursday, April 29.—Military day.

Friday, April 30.—One gallon efficiency contest.

Saturday, May 1.—Carnival parade. Smoker, and award of prizes at Automobile Club of America.

INTERESTING STATISTICS OF THE MAXWELL NON-STOP RUN

BOSTON, April 19.—Complete data, showing the effect of the 10,000-mile non-stop motor run, have not yet been compiled by the technical committee, in whose charge the Maxwell car was placed at the finish of the test last Monday afternoon. The car is now in the laboratory of Professor Charles F. Park, of the Institute of Technology, and his examination is so minute that he has not yet completed it. When the report of Professor Park is drafted, it is expected that figures will be given showing just what was the result on every part of the mechanism of more than twenty-five days' continuous running of the motor, and the journey of 10,074 miles, which is what the register showed when the car was finally stopped by President Speare, of the A. A. A.

From the log-book carried on the car during the test, however, some interesting facts have been compiled. In this book was entered a complete account of the car's performance, the mileage per day and per trip, the amount of supplies taken on, and the repairs that were necessary. The motor was run exactly 606 hours and 21 minutes, never stopping from the time it was cranked at 10 o'clock on the morning of March 18, until it stopped in Copley Square at 4:21 o'clock April 12. During that period there were used, according to the log-book figures, 758 gallons of gasoline, making the average mileage per gallon about 13.3. This, however, included time when the car was standing still, but the motor was eating up fuel. There were used 119 gallons of oil and 17 pounds of grease for lubricating purposes. The consumption of oil was much greater than on an ordinary touring car, because a very light oil was used in large quantities.

In the total duration of the test, 606 hours and 21 minutes, the car itself was standing still with the motor running 39 hours and 40 minutes. In that time the car would have covered, had it been in motion, approximately 600 miles. The time during which the car stood still was consumed in taking on gasoline and oil, changing drivers and observers, changing tires and making repairs. There were eight tire punctures, the rear axle was changed, a spark plug and a push rod replaced. Several spring leaves had to be replaced. In all the car made 156 round trips from Boston to Worcester, Providence, Newburyport, Nashau, Marlboro and Framingham, making an average of 65 miles per trip.

Members of the technical committee, who are the only persons that have ridden in the car since the end of the test, were surprised at the smooth manner in which the motor was running.

Splitdorf Gives Dinner to Maxwell Drivers.—In recognition of the good work of the drivers who handled the Maxwell car in its 10,000-mile test, Charles F. Splitdorf, maker of the Splitdorf magneto and coil, with which the Maxwell was equipped, on Tuesday evening gave a dinner to the drivers and the members of the Maxwell Company at the Hotel Thorndike. Through the run the Splitdorf magneto gave the best of service.

Atlanta's Big Auditorium, Nearing Completion, Where "National Automobile Show of the South" Will Be Held in November Next.

CANDIDATES FOR WESTERN CUP RACES.

CHICAGO, April 20.—Frank H. Trego, general executive in charge of the two races of the Chicago Automobile Club—light car event, June 18, and Cobe cup, June 19—started out Monday night on a canvassing trip to Western factories for the purpose of getting a correct line on the probable entries for the two big Western road races. He has mapped out a circuit, taking in Flint, Pontiac, Jackson, Detroit, Indianapolis, and Cleveland.

The first stop at Pontiac resulted in the positive assurance that the Buick will have three cars in both events, with Strang, Burman, and Chevrolet as drivers. A visit to the Oakland factory at Pontiac unearthed a possible condidate which hitherto had not been figured upon for the Cobe cup.

While Trego has been away home folks have been busy, and yesterday it was announced as almost certain that a Renault will compete in the light car event, with the driver probably George Schoeneck. Another candidate for the light car race which had been overlooked by the census takers is the Corbin, and the Bird-Sykes Company has opened negotiations with the factory with a view to making an entry. Louis Geyler, Stevens-Duryea agent, also announced yesterday that his company is likely to nominate one of the four-cylinder models.

ANOTHER TAXICAB COMPANY LAUNCHED.

New York wisely has the taxicab habit beyond all hope of recovery. The latest applicant for a share of the public favor is the W. C. P. Taxicab Company, which has been organized by C. F. Wyckoff and E. S. Partridge, of Church, Wyckoff & Partridge; and A. R. Rockwell, F. E. Moscovics and De Witt Page, of the Bristol Engineering Company, Bristol, Conn. The vehicles of the new company will be popularly known as the "yellow taxi," from their coloring; the chassis and lower portion of the body is painted orange yellow, striped with black, and the hood and upper part of the body black.

The cabs, which are to be built by the Bristol Engineering Company, will embody several new features. The driver will sit on the left-hand side, with the levers in the middle. The taximeters will be driven from the front wheels, so that their measurements may be as accurate as possible, especially in slippery weather. The first "yellow taxis" are already on the streets. They will be operated from the garage of Wyckoff, Church & Partridge, at 232 West Fifty-sixth street.

ACCESSORY CONCERNS FORM COMBINE.

Announcement was made Tuesday of a selling plan involving five of the best known concerns in the trade, to be backed and managed by men who have been eminently successful in the marketing of accessories during the past few years.

The new corporation, with a capital of $100,000, will be known as the United Manufacturers. It will act as a co-operative selling and distributing organization, handling the business of the Jones Speedometer, Inc., Weed Chain Tire Grip Co., C. A. Mezger, Inc., Connecticut Telephone & Eelectric Co., and N. Y. & N. J. Lubricant Co.

Jones speedometers, Weed chains, Soot-Proof spark plugs, Automatic windshields, Connecticut coils, and Non-fluid oils are the products that will be handled.

The organization will be owned and personally managed by the individual manufacturers who compose it. Plans at present include New York headquarters at Broadway and Seventy-sixth street, and branches in Detroit, Boston, Chicago, and Cleveland, with other branches to be opened later.

The president of the new organization will be W. B. Lasher, of the Weed Chain Tire Grip Co., while the other officers are R. M. Owen of C. A. Mezger, Inc., vice-president; Robert H. Montgomery, New York, secretary; George L. Holmes, of Jones Speedometer, Inc., treasurer.

As might be expected, the objects of the new organization are to concentrate the selling efforts of the interested companies and to reduce the expense of selling and distributing. On account of the branch house system, it will bring the selling company in closer touch with its customers. The new corporation will do no retail business, concerning itself solely with the jobber and dealer.

AUTOISTS USE THE WIRELESS "C. Q. D."

Two Newark, N. J., automobilists, Will H. Linkroum and A. Frederick Collins, have perfected a wireless telephone which can be carried in a suit case. One day last week they took the apparatus with them in Linkroum's Lozier car, and Collins, the inventor, held wireless conversations with the Newark office, one being from the Morristown Pike road, twenty miles away. Mr. Linkroum believes that the wireless 'phone will be of great assistance to automobilists in obtaining help in case of accident. The only difficulty is the necessity of having the garages previously equipped with similar instruments.

FOR THE MAN BUYING HIS FIRST CAR.

As the first days of warm weather appear and the roads begin to dry into passable condition, it is customary to give forth a word of advice and exhortation to those about to make their first plunge into automobiling. Never before have the cars been so good or so cheap; never before have there been so many profits and pleasures to be realized from their use—does this sound familiar? Yet, even at the risk of bromidism, we must repeat it. Perhaps some new reasons can be brought out to show that this, above all others, is the year; so that the stragglers, as of old, will fall into line and dim longings will be aroused in minds heretofore unmoved by the demonstrator and his seductive efforts.

Those to whom this preachment is especially addressed we may divide into two classes: the doubtful, who are not persuaded of the advantages of being an automobilist, and the timid, who, although persuaded, must count the cost. The former we can only advise to secure as many rides, runs, and demonstrations as possible; for their hesitation can only come through lack of experience. So let them pester the expectant agent and the complaisant friend; may these long-suffering teachers be rewarded hereafter, if not on this mundane sphere.

To the timid, fortunately, we can give facts and figures. This year for the first time the possibilities of the light, low-priced car are beginning to be realized. At $1,500 and less there are a dozen different makes, any one of which can be depended upon to give satisfaction; they will run twenty miles on the gallon of gasoline, and their tires will stand the wear of five thousand miles. The useful life of one of these machines can only be guessed at. There are cars of the vintages of 1904 and 1905 which will be in active service again this Summer, albeit a trifle antiquated in appearance; and allowing for the improvements in construction since those days, these new cars should last nearer ten than five years. As for the chauffeur, the light car knows him not; the owner drives, and doubles his enjoyment thereby.

So snap the whip once more, and round the stragglers into line; delivery dates are going fast, and now is the time to buy!

* * *

LAW MAKING IS IMPROVING.

Common sense treatment of the automobile is evident as one State legislature after another concludes its annual session. Pennsylvania has improved its law in many ways, and it will now welcome the automobilists of other States, providing the other States similarly welcome the autoists from the Keystone commonwealth. New Jersey has also become quite liberal, though its reluctant politicians would insist upon a measly dollar fee for visitors. New York now has in mind the abolishing of all automobile speed limits and the making of drivers responsible under the same law which covers other users of the road. The fee is to be an annual one, as in many other States, but the abolishment of the miles-per-hour iniquity and consequent "trapping" will be considered by most automobilists as a good trade under the circumstances. Other legislatures are still busy, but the grist that has already come from the law-making mill is indicative of the changed attitude of public and politicians generally. Connecticut still bears the palm for the most liberal and sensible treatment of motor-driven vehicles, and this despite the fact that its legislature is composed in great part of farmers and men from small towns. And the "Nutmeg State" has roads worthy of the name.

* * *

"WE SHOULD WAIT AND WATCH."

Here is some editorial comment from the New York *Times* which supplies material worthy of fair-minded consideration by the man who has yet to become an automobilist in one form or another:

Automobile accidents are undoubtedly numerous, and too numerous, but it is doubtful if their number increases in anything like the same proportion as does the number of automobiles, and it would be only fair, in making up the account, to cross off a good many of them as only taking the place of accidents which, if it were not for the new vehicles, would be happening to users of the vehicles they replace.

Another thing to remember is that for innumerable centuries humanity has been learning how to keep out of the way of horses and the carriages they draw, while its experience with automobiles began less than twenty years ago, and evasion of them has not yet become instinctive and automatic. All of us can remember when "the murderous trolley car" claimed its daily victims, and motormen were the constant objects of just such denunciation as the chauffeurs are now receiving. The cars are run to-day much as they always were—only faster—but, considering their enormous number, they do little harm.

Of course, there is in all this no excuse for the doings of reckless, drunken, or incompetent chauffeurs, and the problem of their proper control or abolition must be studied till a solution of it is reached, but there is some reason for viewing the situation as it is. We may be happy yet, even with the automobiles steadily increasing in numbers daily.

NEW YORK TO PAY ANNUALLY AND ABOLISH SPEED LIMITS

ALBANY, N. Y., April 19.—As the result of the conference held between legislators and representatives of the automobilists, an agreement last week was reached on the provision of a new motor vehicle law, which was quickly introduced in the form of an amendment to the State highway law. The measure is now in the hands of the Finance Committee of the Senate.

The agreement included the taking of the Allds-Hamn bill of last year; which was reintroduced early this session, and the making over of it where it did not coincide with the plan and scope of the conference.

Horsepower to Be the Basis.—By the proposed new law horsepower is to be the basis of the registration fee whereby automobile owners are to pay their share toward the repair and maintenance of the highways of the State.

The provision settled upon was that of the uniform laws commission of last Summer, with a slight increase over its rates. It is provided in the new bill that each owner shall pay an annual fee to the Secretary of State of $4 for each car he owns of 20-horsepower or less; $6 for each car of between 20 and 30-horsepower, and $10 for all machines of over 30-horsepower. This is expected to raise an annual revenue of over half a million, which shall be turned over to the State treasury to be used for the repair and maintenance of highways.

All Speed Limit Laws Are to Be Repealed.—There will be no speed prescribed as lawful, and therefore there will be no auto-traps and no graft for the country or other justices. The motor vehicle driver will be placed on the same equality with the driver of a horse-drawn vehicle in that neither may drive recklessly so as to endanger life and property at any rate of speed. This will make it possible to **arrest a reckless driver on a congested street** who may be driving at a speed of not more than five miles an hour and yet may be endangering the lives of pedestrians. The same vehicle may be driven 20 miles an hour early in the morning without endangering anyone.

The penalties prescribed are a fine of $50 for the first offense; a fine of $50 or thirty days' **imprisonment for the second offense**; and a fine of $50 and thirty days or possibly six months' imprisonment for the third offense, and a clause for the suspension of the driver who thrice offends may be put in. These penalty clauses may be worked out somewhat differently before the bill is passed.

Professional chauffeurs are to pay $10 for their first license and $5 a year for its renewal; the Secretary of State shall furnish an official badge, the design and color of which he shall determine, and the color shall change each year.

The common rules of the road, which seem to have been left out of the highway law, will be reinserted **to cover all vehicles** using the highways, and fixing by statute that vehicles meeting shall turn to the right and shall pass to the left, etc.

Among those present at the conference were: Senators Allds and Heacock and Assemblyman Hamn; H. A. Meldrum, president of the New York State Automobile Association, and Oliver A. Quayle, chairman of its legislative committee; Superintendent of Insurance William H. Hotchkiss, ex-president of the A. A. A.; F. H. Elliott, secretary of the A. A. A.; Charles T. Terry, representing the National Association of Automobile Manufacturers; Alfred Ely, representing the Automobile Club of America; Giles Stillwell, of Syracuse, and several others.

The wording of the new law, which is to obviate the present speed limit provision is this:

> Every person operating a motor vehicle on the public highways of this State shall drive the same in a careful manner and at a rate of speed so as not to endanger the life or limb or property of any person.

The anti-joy ride and anti-tampering provision is as follows:

> Any person using or operating, driving, injuring, or tampering with a motor vehicle without the permission of the owner is punishable by a fine of not exceeding $100, or imprisonment of not more than six months, or the suspension of the right to operate a motor vehicle as a registered chauffeur for not more than six months, or all of such penalties.

Automobiles used solely for commercial purposes, or which are propelled by electric battery power, or are used or to be used solely within the confines of a city, are to pay only a nominal license fee of $2, without regard to their horsepower, as they would not use the good roads.

The registration fees imposed shall be **in lieu of all of the taxes**, general or local, to which motor vehicles might be subsubject as personal property.

PENNSYLVANIA, LAW IMPROVED, GRANTS RECIPROCITY

HARRISBURG, PA., April 19.—Reciprocity for automobilists from other States; an increased speed limit; uniform speed and license regulations; a new rate of fees; and the provision that all fines shall be reported to the State Treasurer, are the subjects which have been accorded special treatment in the Keystone State's new automobile law. These features are embodied in the Townsend Senate bill, which after an intermingling with the Grim House bill, has finally passed the Legislature and but awaits the signature of the State's autoing executive, Governor Stuart, to make it a law in immediate effect. The Pennsylvania Motor Federation figured much in the passage of the measure.

Broad-minded in its provisions, and superseding other statutes with which general fault has been found, the enactment is a pleasing one to automobilists, representing the result of a great deal of hard labor against a few legislators who would have had narrow policies enforced. Of premier importance is the clause which allows tourists from other commonwealths to enter the borders of this one without having to make extensive arrangements for being licensed beforehand. A limit of ten days is set, however, during which the license tags of **States which similarly recognize** those of Pennsylvania, will permit the use of the roads. There is no statement in the law preventing a visitor from being within the State for more than one period during a year.

The licensing of resident cars and owners will hereafter be carried out along different lines from those now in effect. A fee of $5 is required for cars of less than 20-horsepower; $10 for those of more than 20 and less than 50; and $15 for those of 50-horsepower or more. Motorcyclists are required to pay $2, but do not have to carry tags.

Dealers and manufacturers will be allowed to have five sets of licenses and tags, and each set will be sold for $5. In addition, the operators of these company cars must be licensed, at $2 each, and must wear badges.

Uniformity was a prime requisite asked by automobilists, and their desires have been heeded, in at least two particulars: that the State law should be the only one, that municipalities should not be allowed to issue city licenses, and that all such regulations in effect now shall be declared void. This was mainly a hit at the Quaker City, which has required operators to take out local licenses. The other consideration is that of speed, for by the new law 24 miles per hour is set as the maximum legal limit, with 15 as that required in built-up sections of towns and cities. The only qualifications placed upon this are those of recklessness, and that when approaching a street car which has stopped to dis-

charge passengers, the automobilists must stop or not endeavor to pass on the side from which persons are alighting. The speed law cannot be altered by localities, except in the case of public parks, which may restrict the speed, but not to a lower degree than that of other vehicles.

In the matter of fines there was a determined effort on the part of automobile owners, through the clubs, to have some regulations which would stop the petty graft known to have been carried on by a number of township officials, justices and constables. Opinions were divided as to whether the fines should be turned into the State treasury, to be used in road construction, along with the license fees, or whether they should be allowed to remain in the townships, but with requirements as to reports which would prevent misappropriation. It was finally decided that the fines for speeding shall be used by the townships authorities, but the collectors who receive these fees are now required to give a sworn detailed statement quarterly. All penalties imposed for other acts than fast traveling must be sent at once to the general State fund.

Prevalence of joy-riding and flagrant use of cars influenced those who framed the act to aim directly at the atrocious custom, especially in the matter of fines, and they are now exceptionally heavy: $100 to $300 for the operation of a car by an intoxicated person, with the probability of a year in jail, or both, and a suspension of the license. A sum of $100 is the cost of using a car without the knowledge of its owner, and perhaps a year.

For speeding, however, the penalties are not so large, ranging from $10 to $25 for a first offense; a send offense within a year may cost between $25 and $50, or 20 days in the county prison; and a third dereliction is rated at from $50 to $200, or 30 days. Jury trials may be obtained, if desired.

Constables and officers may arrest upon sight without a warrant, but must file with a magistrate an affidavit setting forth the reasons, and furnish the autoist with a copy. If a car is seen violating the provisions of the law, the license is taken as prima facie evidence that the owner is in it, and he will be held responsible unless he can show who was really the operator.

The Townsend bill will go into effect as soon as signed, except as relating to the licensing of Pennsylvania residents, who shall be governed by the present statute until December 31, 1909.

NEW JERSEY LAW BROUGHT FAIRLY UP-TO-DATE

TRENTON, N. J., April 19.—Governor Fort today signed three of the six automobile bills passed by the legislature, and announced that he will sign the remaining three on Wednesday. Automobilists all over the State are elated at their success in obtaining the passage of these measures, which at least eliminate all the medieval features of the former statutes and in some respects are an advance upon those of some other States. Complete reciprocity in the licensing of non-residents has not yet been granted, but they are permitted to remain in the State for eight consecutive days, or for four periods of two days each, on the payment of a fee of one dollar. Offsetting this is the provision that all vehicles must carry a light at night—a feature which automobilists have always advocated.

The three bills which are now law provide as follows: First, that it be a misdemeanor to drive an automobile without the consent of the owner, or while in an intoxicated condition, or for a bet or wager, or to break a record, or after license has been revoked, or to fail to display a registration number or to display a false registration number; second, that the funds already collected from licenses, registration fees, and fines, amounting to about $300,000, be released for immediate use in road repairing; third, that the Commissioner of Roads be given two competent engineers as assistants.

Of the measures which will be signed Wednesday, the first is that providing for the lighting of all vehicles at night, on penalty of a fine of one dollar for each offense. Non-residents are permitted to use their machines in the State for a limited time, as explained above; the licenses may be obtained on written application, inclosing the fee of one dollar, and in case the applicant is properly registered in his home state, he need not take out a driver's license in New Jersey. The last and, at least to the native automobilists, the most important bill does away with the absurd requirement of numbers on the front lamps, fixes twenty-five miles an hour as the maximum speed limit in open country where the houses are more than 100 feet apart, and reduces the fees allowed justices of the peace, constables, and witnesses to such a low figure that there will no longer be any incentive to make wholesale arrests.

The passage of these bills is an example of the power which can be wielded by a firm organization of clubs. The automobilists carried on their campaign in a businesslike way, obtaining the aid of boards of trade and other influential associations all over the State. Much credit is due Joseph H. Wood, chairman of the legislative committee of the Associated Automobile Clubs of New Jersey, for his constant and fruitful activity. As a result of their efforts the automobilists have obtained a reasonable and consistent law, which grants freedom from petty annoyances in the guise of "Jersey justice," and which will no longer drive away their visitors.

In the past New Jersey's reputation has kept away thousands of tourists who otherwise would have spent weeks at the beaches and summer hotels. The greater prosperity of these resorts should serve as an example to other States of the advantages of an equitable automobile law.

CONNECTICUT TO HAVE COMMISSIONER OF MOTOR VEHICLES

HARTFORD, Conn., April 19.—The automobile bill drawn up by the committee on roads, rivers and bridges, as well as the bill providing for the establishment of the office of commissioner of motor vehicles, was reported to the Senate and is due to be taken from the table this week. The commissioner ot motor vehicles measure is not regarded with any great enthusiasm by the automobilists of the State, but they believe that if it is rejected they may expect the enactment of a law giving justices' courts the power of revocation of licenses. That, of course, would mean chaos, and the former bill seems the lesser of the two evils. It is possible to secure a fair-minded commissioner who will be reasonable in the execution of the automobile laws, whereas if the rural courts should have the power to keep an owner from using the roads, because of the revocation of the license, this State will not be the most pleasant one for automobilists. The hotel men have joined the auto people in the demand for proper consideration of tourists.

The chief objection to the bill drawn up by the committee on roads, rivers, and bridges is the provision calling for a speed of ten miles per hour at intersecting streets. It is pointed out that this would give the country constables a fine opportunity to re-establish their speed traps, which have been decidedly in the background under the present law. Considerable opposition in both houses is expected from the representatives of the rural districts, as there is still much feeling against out-of-State automobilists who habitually drive at express-train speed.

PITTSBURGH GAINS SOME NEW FACTORIES.

PITTSBURGH, April 20.—Greater Pittsburgh is soon to get three automobile manufacturing plants, if present prospects count for anything. This city has turned out to be one of the best automobile buying centers in the country, and this has encouraged manufacturers to seek locations near Pittsburgh for their new plants. The new plants which will be located in this district are those of the Belden Motor Car Company, the Perfection Magneto & Commonsense Auto Company, and a new concern headed by C. P. Munch, general manager of the Buffalo & Susquehanna Coal Company, of DuBois.

The Belden Company has been located in this city for several years, with offices in the Bessemer building. Its new car, the invention of Edward H. Belden, elicited much comment at the recent local show. The company has practically decided to locate the plant at Ambridge, the new industrial town, 30 miles down the Ohio river, where the great plants of the American Bridge Company were located five years ago. The plant for which plans are now being prepared will employ at least 2,000 hands, and definite announcements regarding it will be made within the next 60 days.

The Perfection Magneto and Commonsense Automobile Company last week bought the property of the Ambridge Lumber Company, also at Ambridge, and will move its factory there from Anderson, Ind. Just as soon as improvements are made to the plant the company will start work with 50 men to manufacture specially designed automobiles and magnetos. The company later expects to employ 150 men. F. C. Borden, president of the company, has been in the Pittsburgh district for several weeks negotiating for a site. He is also secretary of the Sanitary Manufacturing Company, of Salem, Ohio, and the Pittsburgh manager of the Russell Engine Company, which has a capital of $1,500,000. T. K. Bevington will be general manager of the Commonsense Company.

C. P. Munch is promoting the third concern which proposes to manufacture automobiles in this district, and it will complete its organization probably this week. The company will have ample capital. The car which it will manufacture will be known as the "Pennsylvania No. Six." It has been manufactured hitherto at Massillon, O., by the W. S. Reed Co., and was there known as the "Massillon Six." Orders for 30 cars have been placed with the Howard Motor Company, of Yonkers, which will manufacture the new machine until a plant can be erected. W. S. Howard is identified with the new company. The "Pennsylvania No. Six" will sell for $2,250, and the plant proposed will employ at least 500 men.

"Pittsburg Six."—For more than a year another car has been manufactured very successfully at New Kensington, Pa., twenty miles up the Allegheny river. This has been known as the "Pittsburgh Six," and is a good seller in this district. Commercial vehicles have also been manufactured in Pittsburgh on a small scale, and it is possible that a plant may be built soon.

A. C. A. HAS TALK ON TIRES.

NEW YORK, April 20.—Demountable rims and other improvements in tire construction and application were thoroughly discussed this evening before members of the Automobile Club of America. Representatives of several large manufacturers explained the merits of their particular goods, with opportunities given for the deflation of their arguments. The new demountable rims were given the most time, for there were several shown and demonstrated which have but recently been exploited. Those who spoke were: P. W. Litchfield, superintendent of the Goodyear Tire & Rubber Company; Alexander Dow, Dow rims; F. G. Hill, Republic; J. B. Cothran, Continental; Orrel A. Parker, Newmastic; C. B. Whittelsey, Hartford Rubber Works factory; Marcus Allen, Empire; Dr. Doolittle, Doolittle rims; and A. Harris, Kempshall. Previous to the tire talk the Snell method of storing and supplying gasoline to garages was explained, illustrated with a working model. About 200 club members and friends attended.

TOLEDO SALE AND POPE COMPANY PLANS.

HARTFORD, CONN., April 19.—In the event of the sale of the Toledo plant of the Pope Manufacturing Company, it is the intention to retire the issue of $266,000 of the six per cent. notes due August 1, 1910, and by appropriation of about $50,000 from the current earnings the company will be able to take up the issue of $267,000 which matures August 1, 1909. Such action would leave earnings of about $350,000 applicable to the two classes of stock in the event of the consummation of the sale of the Toledo plant to the Overland company, which is now regarded in this section as a foregone conclusion. It is assumed that through the reorganization of the Pope Company, the operation of the two plants at Hartford and Westfield would net an annual income of about $400,000. With these earnings the company could pay 6 per cent. on the $2,500,000 of preferred stock, and then have a remainder of $250,000 for the $4,000,000 of common stock. Whether these sums will be distributed will depend on the financial situation and the policy adopted by the board regarding the accumulation of a surplus and a working capital. It is expected here that the sale to the Overland interests will net the Pope Company about $500,000.

TRANS-PENNSYLVANIA ROAD ASSURED.

HARRISBURG, PA., April 19.—Pennsylvania will have a trans-State highway, from Philadelphia to the Ohio State line, including Harrisburg en route. Such has been provided for in the highway bill which was passed last week just as the Legislature was about to adjourn, and which had a stormy voyage between the two houses before it was adopted. The movement was started toward finality by Governor Stuart, who has fostered the matter since it was first suggested, even to touring over proposed routes, and the dream of a fine road across the commonwealth will probably be realized before long.

Within six weeks, funds aggregating $3,000,000 will be available for the commencement of the undertaking, to be spread over two years from May 31, with an additional million in each of the two following years, the entire sum set aside being $5,000,000.

SELDEN FACTORY NOT DAMAGED BY FIRE.

ROCHESTER, N. Y., April 19.—Since the recent disastrous fire in this city the Selden Motor Vehicle Company has been busily engaged denying reports that its factory was destroyed. The factory which was burned was one built by Judge H. R. Selden, the father of George B. Selden, president of the present company, and was sold to the Palmer Company. The conflagration did not injure the plant of the Selden Company, and the Selden cars are being produced as regularly as before.

NORTH JERSEY AUTOISTS HAVE ELECTION.

PATERSON, N. J., April 19.—The annual meeting of the North Jersey Automobile Club resulted as follows: President, W. G. Norwood; vice-president, J. N. Faulkner, M.D.; second vice-president, B. Eastwood; secretary and treasurer, James Madden; captain, Harry McGinley; first lieutenant, Charles Frost; second lieutenant, W. M. Jacobus; counsel, Jacob Vanderclock. George A. Post, who has been a most conscientious president for several years, declined a continuance in office.

PETREL WILL MOVE TO MILWAUKEE.

KENOSHA, WIS., April 19.—The Petrel Motor Car Company, of this city, has secured a new factory at 470-480 Virginia street, Milwaukee, where it will be enabled to multiply its present output four or five times. The removal will take place May 1.

GILLETTE TO REPRESENT CONTEST BOARD.

HARTFORD, CONN., April 19.—C. H. Gillette has been appointed official representative of the contest board of the A. A. A. and will have entire control of all automobile contests in this locality.

New Headquarters of Herz & Company, New York City.

THE AMERICAN HOUSE OF HERZ.

Coincident with the enormous increase in the business of automobile manufacturers there has been a parallel one for the makers of automobile parts and supplies, necessitating enlarged facilities for production, a maximum output of high-grade goods and often a change of headquarters. This has been the recent experience of Herz & Company, of New York, Vienna and Stuttgart, which has moved northward along Lafayette street, in New York, to the corner of Houston, where it has found factory space for the extension of its trade. Under the direction of G. L. Herz, who spends half of each year in this country and half in Europe, the new plant is now working day and night to fill its orders for ignition and other specialties, all but a small part of which are used by automobile factories.

The New York factory is used in making timers, distributors, air pumps, spark plugs and shock-absorbers. The Herz magnetos are all made in Germany and imported complete for American use. Wire cables and copper gaskets are also products of the Herz European plants, the reason for this, according to Mr. Herz, being that the more skilful workmen do not leave their home towns and cannot be induced to go away to other countries. Much of the manufacture of these devices requires handwork. At the same time much of the material, such as compressed fiber and rubber, can be secured of higher quality abroad.

By its change in location the metropolitan house is now fully equipped to manufacture the parts which the firm markets; 30 machine tools, many of them special in design and construction to meet the needs, operated by experienced workmen, are in constant use. Castings for the pumps are machined; platinum alloy electrodes for spark plugs are stamped from ribbons of the expensive material; timer cams, ball races and contacts are hardened, and many of the lines are assembled under the direction of the head of the firm. One of the feature machines of the shop is that which grinds the interior of the roller-contact timers.

Six different styles of magnetos are now built by the Herz company and imported into this country. One which is receiving the attention of the makers at present is a light one for aerial ignition, where high-speed work is necessary and high efficiency required. This is one of the lightest devices of its kind ever made, and it gives a very hot spark at low speeds, such as when the armature is revolved by the fingers, being then of such intensity as to jump an eighth-of-an-inch gap. The growth of the motorcycle business in America can be appreciated from the fact that over 4,500 Herz magnetos for this type of machine have been received during the past fiscal year. Of the 12 types of timers made, two have just been put upon the market, of special design and embodying improved features, such as tool-steel contacts, ball bearings, fiber insulation and absolute rigidity. These devices are made in the New York factory, as are also the air pumps, which are used for pumping tires, blowing whistles on motor boats, or for securing air pressure for other uses. A feature of the Herz pumps is that there is no leather about them, the gray iron pistons having two rings of the same material. They are friction driven.

Bougie Mercedes plugs, with double stone insulation, are claimed to be self-cleaning and not open to short-circuiting or fouling. The electrode has six points, instead of one, set eccentrically so that the spark-gaps vary from 1-4 to 1-2 of a millimeter, the idea being to take advantage of the varying intensity of the magneto spark as the speed of the engine changes. These changes are accommodated in the plug. The cleaning property is secured by the construction, which allows the gas compressed in the plug chamber to blow out around the electrode, blowing any oil or carbon deposits away from the electrode.

The business of the accessory manufacturers is a good barometer of conditions of the general automobile business, and of this Mr. Herz says: "The factory business must be enormous, as indicated by the pressure brought to bear upon us for faster delivery of our products. Our orders on file would require us to double our capacity, and we have had to take on night work. The trade this year is utterly beyond comparison with that of a year ago. Then it was not good. I will go to Germany very shortly to hurry affairs there and try to get more material."

One of the Work Rooms in the New York Plant Where the Herz Specialties are Made.

Testing Horsepower of Franklin Engine in Completed Car.
In testing the horsepower of engines at the Franklin factory, Syracuse, N. Y., the engine shaft of the car is connected with a fan dynamometer, by which any desired load can be put on. The revolutions per minute, gasoline and oil consumption, and the horsepower are noted. Ordinarily only the engine is tested, but the testing room is so arranged that a completed car can be admitted, the engine shaft extended out through the rear of the running gear, and complete readings made with the dynamometer.

Rambler Fined for Beating Interurban Car.—An unusual result came of a fast brush between a Rambler touring car and a limited express interurban car on the Louisville and Eastern Railroad, according to Prince Wells, the Louisville, Ky., representative of the Rambler cars. It seems that W. W. Liter of that city, was driving his model 45 Rambler touring car on the Shelbyville pike, which is parallel with the electric railroad, and in a four or five mile race with the fast trolley car, beat it to a crossing on the main pike, the speedometer showing 60 miles an hour. The vanquished motorman and conductor deliberately went into court, and testified against the automobilist, causing him to be fined for fast driving. The judge fined Mr. Liter 1 cent and costs.

Another Pierce for the White House.—A second Pierce-Arrow car for the use of President Taft and his family has been shipped by the Pierce-Arrow Motor Company, of Buffalo, to Washington. The new car is a six-cylinder, 36-horsepower landaulet, and is upholstered in gray whipcord, with the national coat of arms emblazoned upon the door panels. The first Pierce purchased was ordered last February, and is a six-cylinder suburban of 48-horsepower. An extra touring body for this car has been ordered, so that the new landaulet will be used in inclement weather in the summer and fall. All of the bodies are painted a dark blue, with a russet stripe following the lines of the moulding.

The "Diamond" Girl.—The latest and by far the prettiest girl to make her appearance is the "Diamond" girl. This is a large poster sent out by the Diamond Rubber Company and shows a young lady in clown's attire apparently having a fine time at a masked ball. It seems to be unmasking time, for she holds her mask in her hand. The costume of white, with longitudinal blue stripes, contrasts well with the red background, and the effectivencss of the whole is increased by the absence of advertising matter. The only reference to the publishers is the two words, "Diamond Tires," on the buttons of the costume.

Renault Wins New Zealand Trials.—Paul Lacroix, manager of the Renault Freres selling branch, New York City, has received word that a 14-20-horsepower Renault car was the successful contender in the New Zealand Automobile Club's reliability trials which extended over four days. The prize was the Star trophy. There were five competitors, and the Renault and a Star of 12-horsepower furnished most of the interest. Both made perfect non-stop scores on the first three days and on the fourth the Renault lost one point and the Star five, with the result that the Renault won.

Large Increase in Sale of Bakers.—"1909 is unquestionably an electric year," according to F. R. White, general manager of the Baker Motor Vehicle Company, who tells of the remarkable increase in the demand for electric automobiles. Of the business in Baker cars, he says: "Our sales for the month of March showed an increase of 300 per cent. over the best month in the history of our company, and even though we have largely increased our factory force we are running day and night endeavoring to turn out cars fast enough to supply the demand for Baker Electrics."

KisselKar Climbs Steep Texas Bluff.—An incline of 43 per cent., the steepest bluff in the State of Texas, has been successfully negotiated by a 30-horsepower KisselKar, according to advices from Dallas. Carrying four passengers, the car twice made the climb, over a dry bed of a stream filled with crumpled lime stone, shale and ridges. After making the first climb, and reporting it, the feat was challenged, so to prove the veracity of those interested the test was accomplished a second time. It is said that nine other cars tried the hill, but the KisselKar was the first to reach the summit.

Spring Meeting of Mechanical Engineers.—The American Society of Mechanical Engineers will hold its Spring meeting in Washington, D. C., May 4 to 7. Professional sessions will be held at which papers on the conveying of materials, gas power engineering, steam turbines, the specific volume of saturated steam, oil well pumping and other subjects will be considered. The members will be received by President Taft and will be given a special exhibition drill of troops by the War Department.

College Men Plan 3,200 Mile Tour.—Boston has been made the starting point of a 3,200-mile automobile tour through Europe, from Glasgow to Naples, by the Motor Touring Club of Syracuse University. The college men will sail on June 25, with their cars, and expect to be home by September 12, making a tour of 81 days. They calculate their expenses at about $650 per man.

Sells Motor Boats to Autoists.—Among the recent arrivals in New York's automobile row is the Atlantic Company, of Amesbury, Mass., manufacturers of motor boats and engines. Under the management of R. C. R. Binder, a branch has been opened at 1619 Broadway. A temporary branch was opened last Spring and a number of boats sold to men prominent in the automobile trade.

HAPPENINGS AT THE FACTORIES.

Mitchell, Racine, Wis.—Work on the new buildings for the Mitchell Motor Car Company, is rapidly progressing. The new $80,000 office building is well under way, and the masons in charge of laying the foundations for the concrete factory additions have commenced operations. The company is contemplating the building of a circular race course on a tract recently purchased south of the city. This will give a testing ground aside from the public streets and country roads.

Stoddard-Dayton, Dayton, O.—Permits for the erection of a six-story concrete building have been issued to the Dayton Motor Car Company, the manufacturer of Stoddard-Dayton cars. It will be located at the corner of McDonough and Bacon streets, on the site of the present power plant. The latter will be razed, and in the meantime power will be supplied from outside sources.

Peerless, Cleveland.—The Peerless Motor Car Company has increased its capitalization from $600,000 to $3,000,000, under the laws of Ohio. It was formerly a West Virginia corporation. The incorporators were: G. B. Siddall, L. H. Kittridge, F. I. Harding, E. H. Parkhurst, John F. Demsey.

Speedwell, Dayton, O.—The erection of several new buildings is now being planned by the Speedwell Motor Car Company of Dayton, O. An increase of business has required enlarged manufacturing facilities.

Union, Albany, Ind.—The Union Auto Car Company of Albany, Ind., will shortly move to Seymour, Ind., where a new building will be used in the manufacture of touring cars and runabouts. New capital has been invested in the concern.

Lyman, Buffalo.—The Lyman Manufacturing Company of Buffalo, has purchased a brick factory, 46 by 150 feet

in size, which will be equipped for the manufacture of Austin-Lyman automobiles, and for general machine work.

Frisbie, Middletown, Conn.—The Frisbie Motor Company has filed with the Secretary of State a certificate of its action in changing its name to the Frisbie-Heft Motor Company.

Babcock, Buffalo.—The Babcock Electric Carriage Company has arranged for the building of an addition 40 by 100 for constructing electric automobiles.

IN AND ABOUT THE AGENCIES.

Neustadt & De Prez Form Company.—A new selling company for the Pacific Coast has been organized by J. H. Neustadt and Eugene De Prez under the name of the Pacific Sales Corporation, with main offices at 50-56 Van Ness avenue, San Francisco, Cal., which will act as factory sales agent, covering the territory from Los Angeles, Cal., to Vancouver, B. C., west of the Rockies, and doing exclusively a wholesale business—selling manufacturers and jobbers only. Mr. Neustadt and Mr. De Prez are well known to the trade, having formerly conducted an exceedingly successful business in St. Louis, Mo.—that of the Neustadt Auto & Supply Company, and which they sold some six months ago.

Splitdorf Opens European Agencies.—The success of the Splitdorf ignition apparatus at the Paris show, and demands for these goods by European manufacturers, has led to the establishment of Splitdorf agencies in the principal cities. They are: Paris, 88 Avenue des Ternes; London, 139 Long Acre; Turin, Italy, 64 Via Santa Chiara; Brussels, Belgium, 33 Square Guttenberg; and Barcelona, Spain, 433 Consejo de Ciente.

Royal Tourist Branches.—The Royal Tourist Car Company has opened branches in New York and Chicago, the former at the corner of Broadway and 62d street, and the latter at 1253 Michigan avenue. Both of these have excellent locations, and equipped with factory facilities. These houses, as well as the agencies in other large cities, Boston, Philadelphia, Baltimore and elsewhere, have been meeting with great success in selling the new Royal Tourist cars.

RECENT BUSINESS CHANGES.

National Sales Corporation Will Move.—An entire building at 232 West Fifty-eighth street, New York City, has been taken jointly by the National Sales Corporation and the Emil Grossman Company, and will be occupied on May 1. There are three floors, 20 by 100 feet in size, in the structure and, being right in the heart of the automobile district. will give the concerns an additional advantage in the trade. A complete stock of hydraulic and spring-action wind shields, Red Head spark plugs, Peugeot chains and rims and Pirelli tires will be carried.

Henry W. Price Company Changes Name.—The firm name of the Henry W. Price Company, of Rockford, Ill., makers of the "Price" line of gloves, has been changed to the Fried-Ostermann Company, and a radical change made in the policies. E. C. Ostermann states that, "The watchwords of this concern will in the future be 'quality, progression, and aggression.' Both Mr. Fried and myself have been connected with the Price concern for years, and have long. contemplated this change."

Loring Auto Appliance Company Moves.—Having outgrown both its present offices and factory at 1777 Broadway, New York City, the Loring Auto Appliance Company. Inc., has leased the entire building at 42 West 43d street, and will take possession on May 1. A number of new accessories have been taken on, and the concern will be prepared to branch out in these.

PERSONAL TRADE MENTION.

Arthur N. Jervis, one of the pioneer writers on automobile subjects, has been engaged by the Contest Board of the American Automobile Association to send out the official news and other information concerning the "Sixth Annual Reliability Touring Contest" of the A. A. A. This means that the work will be exceptionally well done, and the material which reaches editorial desks will be practically ready for the printer.

Charles C. Craig has been appointed manager of the Chicago branch of the Haynes Automobile Company, to take effect at once, succeeding J. B. Seibler. Mr. Craig is well known in the trade, having been identified with the industry for some years, principally in the capacity of traveling salesman for the Haynes and other companies.

Montague Roberts, the racing driver, has been appointed to the engineering boards of the Herreshoff Motor Company, of Detroit, and the Bristol Engineering Corporation, of Bristol, Conn. Since December he has been testing out the Herreshoff cars at Detroit, and he will do the same work with the new Houpt cars at Bristol.

Otis R. Cook has joined the forces of the Federal Rubber Company of Cudahy, near Milwaukee, Wis., as manager of the tire departments. James W. Devine accompanies Mr. Cook as his assistant. The company has established general offices in Milwaukee, with a branch at Milwaukee and Oneida streets.

Joseph B. Deibler has resigned as manager of the Chicago branch of the Haynes Automobile Company, which he has held for six years. He has not announced his intentions for the present, but in May will take a tour in a Haynes to a Dakota ranch for a vacation.

James Joyce, manager of the automobile department of the American Locomotive Company; C. B. Denney. treasurer of the company, and Leigh Best. vice-president of the company, are rusticating at Farmington. Conn.. making their headquarters at the Country Club.

Gilbert U. Burdette, who has been in charge of Packard interests in Newark, N. J., has retired from the Packard agency, and joined the forces of the Atlantic Motor Car Company. in the management with C. J. McShane.

E. W. McGookin, sales manager of the Stewart & Clark Manufacturing Company of Chicago, has assumed the management of the Detroit branch, at 697 Woodward avenue.

David Landau, of the Palmer & Singer Manufacturing Company, has been appointed chief engineer, in the place of Oscar Stegeman who recently resigned.

Geo. H. Brown, secretary and treasurer of the Winton Company, and Mrs. Brown have returned to Cleveland from a visit to Atlantic coast points.

Charles A. Singer, Jr., has been appointed general sales manager of the Palmer & Singer Mfg. Co.

RECENT INCORPORATIONS.

Gilbert Manufacturing Company, New Haven, Conn.—Capital $12,000. To manufacture motorcycles and motorcycle parts. Incorporators: F. E. Bowers, E. B. Spalding, Louis F. Meyer.

Sterling Gas Machine and Manufacturing Company, Camden, N. J.—Capital $25,000. To manufacture carbureters and gas machines. Incorporators: L. C. Simpson, J. W. Mills, G. A. Darlington.

Barrell Pneumatic Tire Protector Company, Boston.—Capital $50,000. To manufacture and sell auto tires. President, H. A. Crossman; treasurer, R. H. Kammeler; clerk, A. E. Carson.

Commercial Motor Car and Engine Company, Chicago.—Capital $20,000. General mercantile and manufacturing business. Incorporators: W. S. Mills, F. M. Olson, P. W. Kerr.

W. & R. Motor Truck Company, Taunton, Mass.—Capital $50,000. General express business. President, F. S. Hall; treasurer and clerk, F. E. Wellman; attorney, Louis Swig.

Victor Tire Traction Company, Boston.—Capital $50,000. To manufacture and sell tires. President, H. A. Crossman; treasurer, R. H. Kammeler; clerk, A. E. Carson.

Auto Lock Company, Chicago.—Capital $50,000. To manufacture and deal in automobiles and accessories. Incorporators: R. W. Dunn, C. J. Monohan, L. A. Wisner.

American Body Company, Buffalo, N. Y.—Capital $10,000. To manufacture motor and other vehicles. Incorporators: Edward W. Selkirk, E. J. Freitas, J. W. Kelly.

C. N. Cady Company, Canastota, N. Y.—Capital $60,000. To manufacture motors, engines, machines, etc. Incorporators: C. N. Cady, G. B. Cady Jr., Minnie A. Cady.

Omnium Tire Import Company, New York.—Capital $10,000. To deal in automobile tires, sundries and supplies. Incorporators: Simon and Bourchard Haas, Edgar Block.

North Jersey Garage, Morristown, N. J.—Capital $25,000. To manufacture automobiles. Incorporators: R. H. Nevins, R. S. Foster, Joseph Van Dyke, Harvey Archer.

Hilton Manufacturing Company, Boston.—Capital $100,000. To manufacture and sell automobile supplies. President, R. W. Sawyer, Jr.; treasurer, J. S. Stone.

Fulton Livery Company, Fulton, N. Y.—Capital $20,000. To run an auto livery and rent cars. Incorporators: M. A. Thomason, C. A. Reynolds, G. S. Piper.

Sloane Motor Company, Chicago.—Capital $35,000. To manufacture motors and accessories. Incorporators: A. W. Baer, W. W. Sloane, D. M. Carter.

Virginia Garage Corporation, Roanoke, Va.—Capital from $1,000 to $25,000. To do a garage business.

Cotta Transmission Company, Rockford, Ill.—Capital $40,000. To manufacture automobiles and acessoriecs.

NEW AGENCIES ESTABLISHED.

Middleby: New York City.—Audobon Garage & Machine Works, 415 West 150th street, for New York City, except Brooklyn. D. L. Ormsby, proprietor.

Selden, Atlanta, Ga.—Selden Car Company, Columbia Garage, Edgewood avenue and Ivy street, G. G. Reid, sales manager.

Rambler: Lawrence, N. J.—Frank W. Thatcher.

Maxwell, Elmira, N. Y.—Jennison & Shea.

End of a Joy Ride.

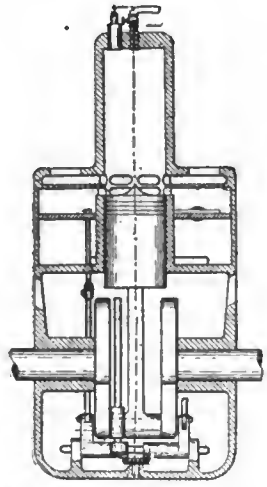
A borrowed touring car dashed down Michigan avenue, Chicago, and into the window of the Firestone Rubber Co.'s branch as if in search of the non-skids which it lacked.

SOME SELECTED AUTOMOBILE PATENTS

Issue of April 6, 1909.

916,972. Explosive Engine.—Linton T. Bassett, Salem, Mass. Filed Jan. 3, 1908.

The Bassett motor has an air cylinder concentrically placed around the lower extension of the cylinder walls. Within this is an auxiliary piston driven off of ths crankshaft, which automatically uncovers an air port at the bottom of its stroke. The air entering there passes through the auxiliary piston and on the up stroke is compressed and forced into the cylinder proper.



Bassett Two-Cycle Motor.

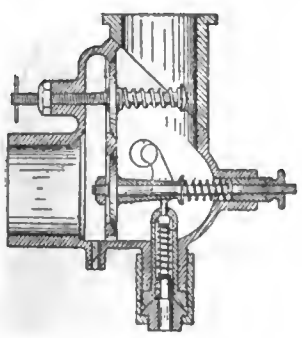
It is free to do this, as the main piston, at the bottom of its stroke, uncovers ports communicating with the concentric air chamber. Immediately above these, but separated from them and open to the atmosphere, are a series of exhaust ports. The engine is evidently intended to be run two-cycle with fuel injected at the proper point in the compression stroke so that the heat of compression will ignite the charge, as in ths Diesel engine.

916,999. Air-Heater for Gasoline Engines.—Charles B. Chambers, Milo, Mo. Filed Jan. 25, 1908.

917,001. Wheel.—Carlton B. Chase, Worcester, N. Y. Filed March 19, 1908.

917,125. Carbureter.—Burt N. Pierce, Indianapolis, Ind. Filed Jan. 24, 1907.

This is an ingenious attempt to have the suction of the engine, which operates the air valve, control through this medium the inflow of gasoline as well. The end of the



Pierce Floatless Carbureter.

air valve stem is made tapering and the increase in this taper operates to increase or decrease the flow past the needle valve. A plunger is spring held against this stem and its lower end is formed to a point and acts as the needle valve.

917,165. Rotary Explosive Engine.—Carlo Sella, Biella, Italy. Filed Oct. 12, 1906.

917,205. Power Transmission Device.—Edward P. Warner, Chicago, assignor to Warner Clutch Company, Chicago. Filed March 30, 1908.

917,220. Friction Device.—Lawrence Whitcomb, Brookline, Mass., assignor to National Brake & Clutch Company, Boston. Filed July 10, 1907.

917,232. Cooling System for Internal Combustion Engines.—C. C. Worthington, Dunnfield, N. J. Filed Sept. 10, 1904.

917,264. Carbureter.—F. W. De Tray, Aurora, Ill. Filed Dec. 30, 1907.

917,283. Internal Combustion Engine.—Warren H. Frost, Los Angeles, Cal. Filsd July 22, 1907.

917,353. Automobile Support.—Alfred J. Parker, Newark, N. J. Filed Aug. 3, 1908.

917,415. Automobile Alarm.—Edwin Copisston, Brooklyn, N. Y. Filed March 28, 1908.

917,422. Motor Vehicle.—Carson Durkee, Vicksburg, Mich. Filed Jan. 9, 1907.

917,463. Transmission Gearing.—E. E. Larson, Thompson, Ia. Filed June 26, 1908.

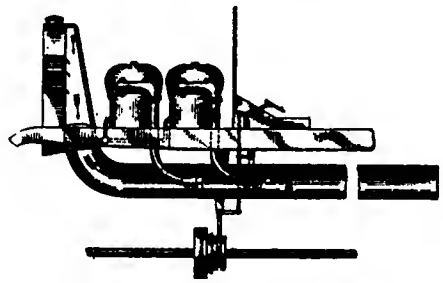
917,465. Motor Vehicle.—John N. Leach, Melrose, Mass. Filed Nov. 25, 1907.

917,493. Tire.—H. E. Schindler, Sisseton, S. D. Filed July 6, 1907.

917,560. Dry Battery Cell.—Walter S. Doe, Jersey City, N. J. Filed May 11, 1908.

917,572. Starting Apparatus for Automobiles and the Like.—Samuel J. Evans, Roanoke, Va. Filed Aug. 8, 1907.

917,598. Emergency Brake.—Jacob Hauser, Scottdale, Pa. Filed Oct. 10, 1908.



Worthington Cooling System.

917,612. Antiskidding Tire.—Eleazer Kempshall, London, Eng. Filed Apr. 20, 1908.

917,613. Non-skidding Tire.—Eleazer Kempshall, London, Eng. Filed April 20, 1908.

These are two American patents taken out by the English inventor whose product is already well known. The Kempshall tire as sold in this country is made with a series of deep depressions in the tread, these being circular with a slightly raised center. The tread portion of the tire is made extra heavy to allow of these depressions having quite a depth. The annular wall around the circular depressions forms a continuous surface at the edges of the tread portion. The circular holes constitute the non- or antiskid part, the idea being that as the holes are pressed to the ground by the weight and speed of the car, the air is gradually squeezed out, forming a series of small vacuums. These do the work of resisting sideways motion.

917,722. Internal Combustion Engine.—James F. Duryea and William Remington, Springfield, Mass., assignors to Stevens-Duryea Company, Chicopee Falls, Mass. Filed Feb. 12, 1908.

This is apparently the first step toward a starting device, consisting as it does of a pressure reservoir connected to the cylinders so that they may be connected.

917,723. Tire for Vehicle Wheels.—Eleazer Kempshall, London, Eng., assignor to Kempshall Tire Company of Europe. Filed July 8, 1907.

917,734. Tire.—Eleazer Kempshall, London, Eng., assignor to Kempshall Tire Company of Europe. Filed July 25, 1907.

Issue of April 13, 1909.

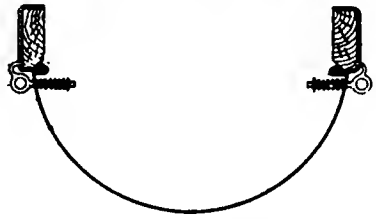
917,764. Friction Clutch.—Harold Horsfall, Pittsburg, Pa. Filed June 5, 1908.

917,845. Spring Wheel.—J. J. Collins, Clemo, Pa. Filed Nov. 1, 1906.

917,883. Vehicle Wheel.—George W. Morris, Racine, Wis. Filer Juns 17, 1907.

917,926. Dust Pan or Shield for Automobiles.—Howard E. Coffin, Detroit, Mich. Filed July 18, 1907.

This is the underpan used on the Chalmers-Detroit cars and as the cut shows, is formed in a semi-circular shape with a lip at the top which hooks over the lower flange of the



Coffin Form of Dust Pan.

main frame. It is held there by means of a clip which is fastened to the outside of the frame section. A spring on the inside of this holds the pan tightly against the frame, which spring may be compressed by the fingers and the pan freed for removal.

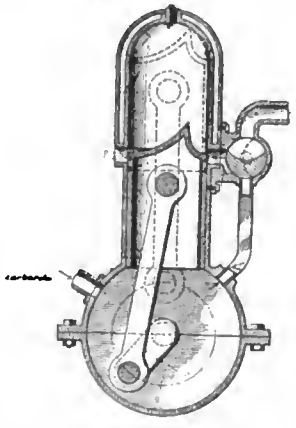
917,941. Valve Gear and Governing Mechanism for Explosion Engines.—Norman T. Harrington, Lansing, Mich. Filsd Jan. 20, 1908.

918,122. Steering Device.—Charles E. Brooks, St. Louis, assignor to Roth Tool Company, St. Louis. Filed Oct. 5, 1908.

918,140. Gasoline Fire Engine.—William F. Gibbs, Philadelphia. Filed Feb. 5, 1908.

918,211. Internal Combustion Engine.—Charles W. Snyder, Hudson, N. Y. Filed April 20, 1907.

This is a two-cycle motor with crankcase compression, but the gas is led from there to the cylinder by means of a bypass in which is working a rotary valve. The latter is so



Snyder Rotary Valve Engine.

proportioned and driven from the crankshaft as to allow fresh air to be drawn into the cylinder on the end of the exhaust stroke and just before the inlet opens. This air helps to clean the exhaust gases out of the cylinder, insuring a full charge of pure gas.

918,429. Shock Absorbing Device.—Claude H. Foster, Cleveland, O. Filed Dec. 4, 1908.

Information for Auto Users

Herz Improved Timers.—Two new types of timers have been produced recently by Herz & Company, of New York, one being a wipe contact and the other having a roller-bearing contact. The feature of the former is in the contact itself, which has been radically changed so as to do away absolutely with any wear. The highest grade of Styrian tool steel, hardened sufficiently

NEW HERZ CONTACT.

to cut glass, is used in the contacts in the rim, the surface of which is subject to wear. The tool steel rim is embedded with an alloy metal which is part of the terminal, and is absolutely rigid. This particular contact has been tested thoroughly, and for six weeks it was run day and night, without showing any perceptible wear. The body of the timer is of rubber, and the revolving center, with

IMPROVED HERZ ROLLER TIMER.

its tool-steel plunger, runs on two sets of ball bearings.

In the roller-bearing timer, the roller is mounted in a square frame, a spring pushed parallelogram, and one of its several features is its compactness. The revolving section is supplied with two roller bearings, and indeed, the roller itself is an annular bearing which is held in a slide, set off the center. This slide is pressed forward by a spring, and though held rigid, will permit of ready self-adjustment. The contacts are made of hardened tool steel, set in vulcan fibre, and ground to caliber on a special machine. The contacts are of the snap type. The workmanship on these specialties is of the same high grade as characterizes other Herz products.

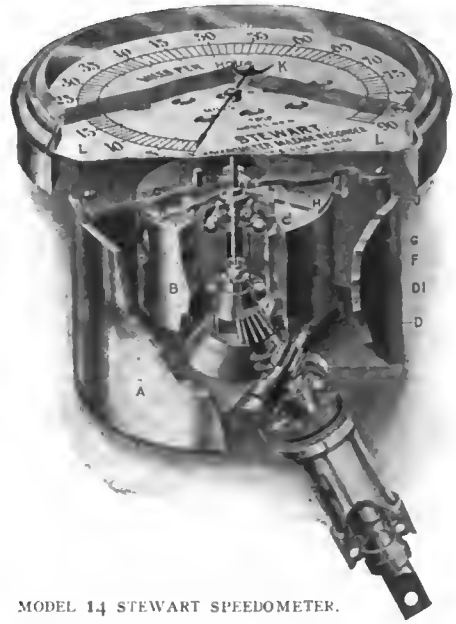
A Novelty in Radial Bearings.—While ball bearings as a rule do not give as much trouble as many other parts of a car, when they do wear and get out of true they are a source of great trouble. It is asserted by many authorities that the fault of most bearings lies in the design and construction of the device used to separate the balls, and breakage or distortion of this part invariably puts the entire bearing out of commission. With a view of overcoming this sort of thing, the makers of the R. I. V. bearing, whose works are at Villar-Perosa, Italy, hit upon an invention of an anti-friction ring of babbitt metal, cast around the balls after they had been placed in proper position in the bearing. The properties of this metal as a "self-lubri-

R. I. V. BALL BEARING.

cating" substance are well known, and by a special process the balls are loosened in this soft metal floating ring to such an extent that they revolve with perfect freedom, yet without the least noticeable play. It is through the fact that this ring is a floating arrangeemnt, and is absolutely free from strain in any direction, and by its very nature frictionless, that it is claimed to be an indestructible device that never gets out of true, at least, up to 30,000 miles.

The balls are made of highest grade carbon crucible steel, perfectly hardened and finished with great accuracy, and the rings into which the balls fit are of the same quality of steel and accurately ground. Among the American manufacturers who have given the R. I. V. bearing an exhaustive tryout, and then placed an order for more, is the Packard Motor Car Company, of Detroit, Mich.

Stewart Multipolar Speedometer, Model 14.—This speedometer makes a special bid for public favor because of its extreme simplicity and costly construction. The mechanism, as shown by the illustration, consists of but two moving parts, the rotor D and the disc H. The rotor, the acuating element, consists of a ring of non-ferrous material in which four permanent magnets are embedded. These magnets are accurately machined from imported Tungsten steel, made to special analysis—the costliest material obtainable for the purpose. The disc, the indicating means, is formed of an alloy



MODEL 14 STEWART SPEEDOMETER.

metal which is exceedingly light and has a low resistance. The rotor rides on hardened ball bearings, the disc on a diamond bearing. To the disc is attached a pointer which moves over an evenly graduated scale, very large in area. The standard or arm upon which Multipolar Model 14 is mounted with a clock is a distinct speedometer innovation, lifting the speedometer and clock away from the dash and making them both easily seen and read. The whole outfit is handsomely finished in brass and possesses unusual style and tone.

Walker's Tire Bands for Preventing Blow-outs.—A convenient form in which to have tire protectors is that of short individual covering strips that are independent of one another. This is the form in which the puncture and blow-out pre-

WALKER BLOW-OUT BAND.

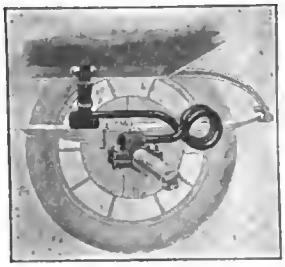
venters made by the Walker Auto Tire Band Company, Indianapolis, come to the autoist. They may be had with or without metal tread mountings, the latter being mounted with 1-8 inch rivets swedged in tapering holes.

Vanguard Spark Plug.—What is claimed to be a spark plug that cannot be fouled or short-circuited by water, oil or carbon, has been patented by the Vanguard Manufacturing Company, of Joliet, Ill. It is shown in the accompanying illustration, and its makers call it "the plug of uninterrupted service." An extended demonstration of the plug to prove that it possessed the qualities claimed for it was made before crowds

VANGUARD SPARK PLUG.

of visiting dealers at the Chicago automobile show last January, and the good record which it made at that time is now having its effect in the large blocks of orders which are keeping its manufacturers busy. The Vanguard Company guarantees the plug not to quit sparking on account of any kind of fouling matter, and it is sold to dealers and individuals under this guarantee. It has terminal caps of a new and special design, adaptable for any old style or quick detachable terminals.

A Simple Shock Absorber.—One of the simplest devices of its character on the market at the present day is the Thomas shock absorber, manufactured by the Buffalo Specialty Company, Buffalo, N. Y. It consists of a combination of a double coiled spring and lever of peculiar construction, built of one piece of special steel and possessing great resiliency. The Thomas has no working



THOMAS SHOCK ABSORBER.

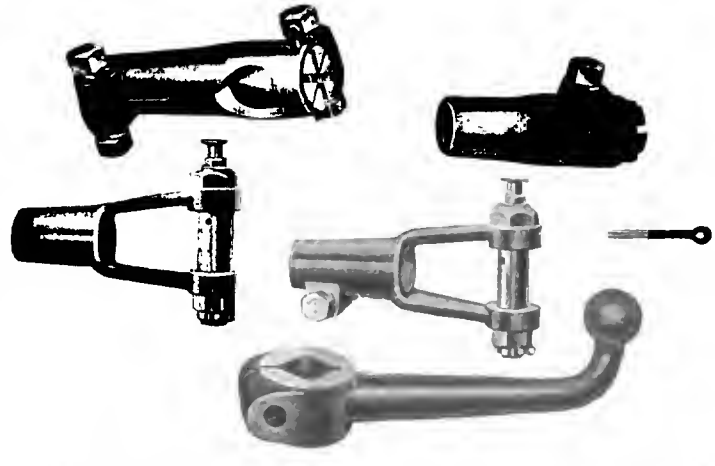
joints, frictions, pistons or plungers, and it is the claim of the makers that they eliminate the jolting and racking upthrow with absolute surety, and prevent the breakage of springs. The manufacturers are now making a special introductory offer embodying a free thirty-day trial, with return privileges if the user is not satisfied with the results.

Latest Thing in Tire Sleeves.—As a first aid to the injured tire the Wiles tire sleeve, a good illustration of which is shown herewith, appears to meet all requirements, for a quick and lasting repair. Although it is of comparatively recent invention, the manufacturers, the Diamond Rubber Company, of Akron, O., is pushed to the limit to satisfy the demands made upon this department of its business. It is claimed for the Wiles tire sleeve that it meets every requirement and has points of superiority in that it is quickly and easily applied, covers every portion of the tire exposed

WILES SLEEVE IN PLACE.

(fitting closely to the rim) and is equally as good for rim cut or blow-out as for tread puncture. It requires no lacing, cannot creep after it is applied, and the quality of rubber and sea island fabric used in its construction gives it the highest degree of wear resistance. A fabric blow-out patch is furnished with each sleeve, so that the same may be applied should the injury to the tire require it. E. H. Harris, of the Diamond Rubber Company, in speaking of the Wiles tire sleeve, says: "Every one who has seen or used it is astonished at its effectiveness and simplicity. More than one auto enthusiast has said to me: 'Why didn't I think of that myself?'"

B. & S. Steering Connections.—The Billings & Spencer improved steering connections consist of five pieces, separate views of each being shown in the illustration which accompanies. The parts consist of a ball-arm, attached to the steering post; two socket connections, with safety lugs for securely binding the adjusting plugs, and right- and left-hand steering arm connections. The two last-named pieces are of new design and are so made as to facilitate adjustment to various sizes of steering arms. Special oil cups are also added. Each connection is a drop forging, made with the customary care for which this house is noted, from the best steel obtainable for the purpose, properly machined and carefully assembled. They are marketed by the manufacturers, the Billings & Spencer Company, Hartford, Conn.



THE BILLINGS & SPENCER COMPANY'S IMPROVED STEERING CONNECTIONS.

Gobbo, God of Good Fortune.—A new idea in mascots, made in bronze and threaded at the bottom so as to fasten

GOBBO, MASCOT.

readily to radiator filling cap. Gobbo's rule of life is "Be cheerful and you will be rich in everything." These mascots are made by the S. M. Supplies Company, Boston.

How Flake Graphite Will Prevent Squeak in Springs.—To prevent springs from squeaking, flake graphite gives instant relief. The springs may be taken off or the leaves separated by jacking the body up so as to take the weight off the springs, then some graphite may be floated between the leaves with kerosene or oil. This will give lasting lubrication and at the same time will not catch dirt or dust as plain oil or grease will. In this connection if Dixon's Motor Graphite, manufactured by the Joseph Dixon Crucible Company, Jersey City, N. J., is used on the inside of tire shoes it will prevent the shoes from sticking and is better than talc or chalk. Rims may be also advantageously treated with flake graphite as a preservative of rust. The application of a thin coating of quick drying shellac varnish, to which some flake graphite has been added has been found to give good results, also if all threaded connections are made with graphite and oil, or, better yet, a specially prepared graphite joint compound, the joints may be taken apart at any time without trouble.

Save Your Radiator.—If you wish to preserve the water jackets of your engine or prolong the life of the radiator, an excellent preservative is that known as Nonkoroda. This is a compound which removes and prevents the formation of rust or scale, thus eliminating expensive repairs caused by leaky radiators. It is made by the Nonkoroda Company, New York City.

INDEX TO ADVERTISERS

VOL. XX NEW YORK—THURSDAY, APRIL 29, 1909—CHICAGO No. 17

THE AUTOMOBILE

"TO commemorate the eleventh anniversary of practical automobile construction in this country," is the reason given by the New York Automobile Trade Association for its second carnival week in the "Big Town" of the country. The affair has assumed stupendous proportions, and unquestionably the attention of the general metropolitan public has been focused on the motor-driven vehicle and its present foundation of permanent stability. With a hill climb Monday wherein the cars easily surmounted the steep grade, record-breaking straightaway performances in Queensboro on Tuesday, and Wednesday devoted to visiting the bunting and flag-decorated stores of "Automobile Row," the carnival is now in successful swing, with more spectacular events to come. To-day will include the transport of the military and a grand opera performance at the Majestic theatre. Friday will be punctuated with a one-gallon efficiency test, and Saturday is to have a big afternoon parade and a concluding evening of jollification in the form of a smoker at the A. C. A.

There has been work in plenty in the preparation and conduct of the carnival, the executive and finance committee of which consists of these leading workers: Gen. John T. Cutting, chairman; Percy Owen, president New York Automobile Trade Association; Frank Eveland, C. R. Teaboldt, Col. K. C. Pardee, C. W. Wurster, C. P. Skinner, Alexander Howell, R. G. Howell, A. J. Inderrieden, and Walter R. Lee, secretary.

When one brings to mind the now historic "run," promoted on Decoration Day, 1896, by John Brisbane Walker, in which two Duryea cars out of six contenders survived the trying journey of 26 miles from the City Hall to Irvington-on-the-Hudson and return, and compares it with the events of this week, he then comprehends the enormous strides accomplished in the making of the greatest industry of modern times. Then the automobile was more or less a subject of jest; now it is a pleasurable necessity.

At the Top of Fort George Hill the Scene Resembled an Outdoor Automobile Show.

National, Aitken Driving, Fastest of the Six-Cylinders.

P. & S. Winner, with Lescault at the Wheel.

Chalmers-Detroit, Star Performer, Knipper Driving.

STOCK CARS REAL FEATURE OF CLIMB.

Though the unthinking public was naturally attracted and enthused by the record-breaking Benz in the contests up Fort George Hill, those given to deduction in affairs of this kind saw more practical performances in the regular stock car events. Out of the field of 41 there were less than a handful of special built racers, and the times made by the stock models were very fast indeed. The 120-horsepower Benz and David Bruce Brown, the combination so successful in Florida recently, flashed up the 11 per cent. grade in 28 4-5 seconds, 3 2-5 seconds better than the best in the 1908 climb and 1-5 better than the record of 1907.

As in previous Fort George climbs the 1,900-foot Belgian-blocked hill, start was standing, with a short dash across the street, through a narrow passage-way, not more than eight feet wide, and then the contestants would be on the hill proper, with a steady rise to the top. Thousands scattered along the walks or the steeper higher ground, some even being in the trees, while at the summit there was a large representation in cars. Perfect weather, a clear course with ample police protection, and good management combined to begin the first actual celebration of the week in ship-shape order. Starter Wagner sent the 41 contestants off in exactly an hour. All sizes of autos were on the list, from the little Maxwell Juniors of 10 horsepower to the big "sixes" of 90 and the bigger fours of 120.

Price classification was used in dividing the stock cars, the free-for-all, of course, being open to all sizes and styles of motive power. Gasoline had full sway towards making records, for this was the only type of car entered, with the exception of the two electrics. The interest for many of the spectators centered in the big fellows entered in the free-for-all and the larger class events, for it was in these that the fastest ascents were made.

The speed averaged from 30 to 45 miles per hour, from the less than half a minute time of the Benz, whose speed was exactly 45 miles per hour average and greater than that on the hill proper, to the six scores of over a minute. Brown in the German racer was followed in :31 1-5 by Webb in a Panhard of 120 horsepower which took part in the 1908 Grand Prix. These two big ones were of special character, and the figures of the stock National "Six," 33 3-5, only 2 seconds less than the Panhard, was a tribute to stock construction, inasmuch as it was the fastest time of the day made by a regular model.

The medium-priced cars of present popularity showed up in fine style, in numbers and in time, there being eight starters in the class between $2,001 and $3,000. A Chalmers-Detroit "Forty" led in :40 4-5, with Bourque in the Knox 2-5 of a second away, and the frequently-competing National third. Buick and Oakland divided the class between the $1,301 and $2,000 marks, Burman winning in :40 2-5. The two Oakland cars with their off-set crankshafts both made the entire run, after the start, upon high speed, Bauer and Dennison taking the climb excellently.

Mrs. Joan Newton Cuneo desired to try the hill in the Knox, but the officials declined to allow her, inasmuch as the event was held under an A. A. A. sanction, and the national body has de

cided that only male drivers shall compete. Owing to the fact that Mrs. Cuneo's name was on the program for a special exhibition event many people expected to see her.

The officials of the day were as follows: Chairman, Col. K. C. Pardee; referee, Robert Lee Morrell; starter, Fred J. Wagner; judges, Alfred Reeves, S. A. Miles; technical committee, A. L. McMurtry, H. H. Law, A. H. Whiting; clerk of course, Alexander Howell; steward, J E. Goewey; announcer, C. T. Earl. The summary follows:

GASOLINE CARS SELLING FOR $850 OR LESS.

Car.	H.P.	Cyl.	Bore	Stroke	Gear Red.	Driver.	Time.

George Robertson, Vanderbilt Cup Winner, Winner of the Four-Cylinder Over $4,000 Class, with 90-Horsepower Simplex.

Knox, Driven by Bourque, Which Captured One Event and Tied First Place in Another.

GREAT SPEED IN JAMAICA STRAIGHTAWAYS.

Rough and dusty was the course on Hillside avenue, Jamaica, Long Island, Tuesday, when the entire attention of the "Big Town's" automobilists was moved across the East river and into Queens borough One and two mile distances had been laid out, electric timing arrangements made, and some 10,000 people gathered along the route to see an afternoon of real sport. Again David Bruce Brown made the feature runs of the day, with the big Benz, its time of 35 3-5 seconds, a rate of 101.69 miles per hour, lowered the world's record for the distance over a road. It was apparent to the spectators that the speed of the great machine was enormous, as it came down the stretch with a thick cloud of dust rolling back from it. The crowd was not highly disappointed when on its first trip on the longer course the timers were not as quick as the car, and no time was caught, necessitating another run. The second trial was probably equally as fast as the first, the time being 1:16 2-5, a rate of 94.24 miles per hour, for the two miles, 2 4-5 seconds better than the score of the Hotchkiss last year. Likewise, Brown's record of 35 2-5 broke that of last season for the mile by 3 1-5 seconds.

But fast as was the German, there were other cars blowing chips from the block of "Old Father Time" during the day, and some of them were real stock cars, with full equipment and only in a few cases stripped. The Knox team made a splendid showing, Dennison in the 48-horsepower car covering the mile in :41 3-5 in the last event of the day, run as dusk started in, at a rate of 86.53 miles per hour; and in the one-mile free-for-all his time was nearly as good, :42 2-5, a rate of 84.9 m.p.h.

The National "Six" took next honors among the stock cars, Merz taking it over the short distance in 44 seconds, an 81.8 miles an hour rate. George Robertson was at the wheel of the big Panhard, inasmuch as his Simplex had been ruled out as not being a stock car, and with the big French car he took second place in both free-for-alls.

It was a peculiar incident, and one which shows the evenness with which the modern stock car develops its power, that the classes were all won by the same cars in the two sets of events.

There were no untoward incidents or approaches to accidents, except in the one mile free-for-all, when Coffey, driving the light Columbia, swung too sharply in rounding the slight curve into the homestretch and appeared to run off the road into the grass. He straightened out, however, and his time was not materially affected, being 54 4-5 seconds. The roughness of the course caused a great deal of bouncing and the few larger holes sent the cars up into the air somewhat. The only event scheduled which was not run was that of running as slow as possible on high speed. It was decided that this would take too long, inasmuch as the Oakland, driven by Dennison, had averaged two miles an hour for the distance in the morning, taking about 30 minutes to go one mile. There were only two entries.

American, Driven by Redstar, Was a Fast Performer.

ONE MILE FREE-FOR-ALL.

WEDNESDAY SOUVENIR DAY—A DINNER-DANCE.

Wednesday's part in the festivities was that of "Souvenir Day," when the dealers in the local trade were given a particular chance to be hosts. "Automobile Row" fairly hummed, and some very pretty and valuable souvenirs were given to recognized customers and friends. A dinner-dance was held in the evening at the Hotel Marseille, 103d street and Broadway, dinner starting at 8:30 with the dance beginning at 11 o'clock.

Stark in E-M-F, Winner of Two Small Car Classes.

THURSDAY, FRIDAY AND SATURDAY.

A military demonstration, including transporting of the Ninth Regiment to Larchmont and a sham battle, is going on this afternoon. About 150 cars were marshaled this morning and taken to the Armory, where the troops were in readiness with full equipment. They were taken to the Heathcote Arms, on the Boston Post road for the active work on their part.

The Imperial Grand Opera Company this evening at the Majestic Theater will have a special performance as a part of the celebration, with "King Guy" and "Queen Annette" attending.

The one-gallon efficiency contest will be held to-morrow (Friday) and should be most interesting. Each car will be given a single gallon of gasoline and sent away on a route not to be announced until the start. The cars will be classed according to price and a basis for accurate comparison will be secured in multiplying the weight (including the passengers) by the distance covered. There will be an observer on each contesting car, and in his charge will be a two-gallon can of gasoline with which to make the return trip. Thos. J. Fay, ex-president of the Society of Automobile Engineers, will act in the capacity of chief inspector of the cars. A. C. Bergman, a member of the society, will assist Mr. Fay.

From the spirited voting for the king and queen of the carnival, interest has been aroused in the pageant which will pass through the upper part of the city on Saturday, starting from Broadway and Eighty-fourth street. Saturday evening the A. C. A. will give a smoker to the Trade Association.

Stearns "White Lines," Driven by Private Owners, Were Out in Force in Their Classes.

Quaker City Has Successful Amateur Roadability Run

By G. M. Schell

L. L. Brown's (Rambler), The Winner.

PHILADELPHIA, April 26.—The second annual roadability run of the Quaker City Motor Club last Saturday afternoon, to Atlantic City, demonstrated that it is quite possible to pull off a real automobile contest without the aid of the professional element and at the same time inject sufficient of the spirit of rivalry to keep the competitors on the *qui vive*—and incidentally refrain from fracturing the speed laws. Sixty-nine cars started from the Hotel Walton, J. C. Bartlett's Woods electric coupé taking the word at 1 o'clock sharp, the others following at one minute intervals. The route, via Egg Harbor and May's Landing, was 68.2 miles long, and the official secret time, set by Mayor Reyburn, of this city, was 3 hours 46 minutes 30 seconds.

George Proud's Rambler, driven by Ira Brown, was declared the winner of the "grand" prize, coming under the wire just 22 seconds before the official limit expired. The "place" prize went to "Dick" Sellers, who drove his Pennsylvania over the course within 1 minute 43 seconds of the mark set by the Mayor. E. C. Benson captured the "show" trophy with his Apperson, handing in his card but 2 minutes 17 seconds shy of the mark.

A unique feature of the contest was that every contestant participated in the winnings, even the last to finish coming in for something. Secretary Harbach evolved the scheme, and it worked out beautifully. Those cars which finished fourth to thirteenth, inclusive, captured series A prizes; from fourteenth to twenty-fifth, series B trophies; from twenty-sixth to fortieth, series C emblems; from forty-first to sixtieth, series D prizes, and from sixty-first on, series E awards. The farther away the car finished from the official figures the smaller the value of the prize. It was a decidedly novel scheme and made a marked hit.

The Mayor distributed the prizes on Saturday evening on Young's New Million-Dollar Pier, whither the cars were taken after the run and put on exhibition. The impromptu automobile show attracted thousands of the elect who flock to the City-by-the-Sea at this season of the year.

The performance of the day par excellence was that of the brace of Woods electric coupés, driven respectively by J. C. Bartlett and George Daley. Despite a 35-minute holdup at Hammonton to enter security for having scared a horse into smashing its rig, the former brought his car to the finish in 4:35:40 on one charge of "juice"—and with about 15 miles left in his batteries. Daley did the same trick in 5 hours 12 minutes. This double performance of the Woodses is said to be the first on record in a regularly sanctioned contest in which cars of all powers had entered. Mrs. Leslie Carter, the well known actress, had her yellow Thomas Flyer in the run, and the rig, with its uniformed crew and two pretty theatrical-looking ladies in the tonneau, made a hit. Countess Von Holstein's Oldsmobile was also a contestant. The following summary shows the order of finish, drivers and the time variation from the official figures:

Place.	Car.	Driver.	Penalties. h. m. s.
1	Rambler	Ira Brown	0:00:22
2	Pennsylvania	Richard Sellers	0:01:43
3	Apperson	E. C. Benson	0:02:17
4	Elmore	F. Hardart, Jr.	0:02:30
5	Elmore	R. E. Ross	0:02:35

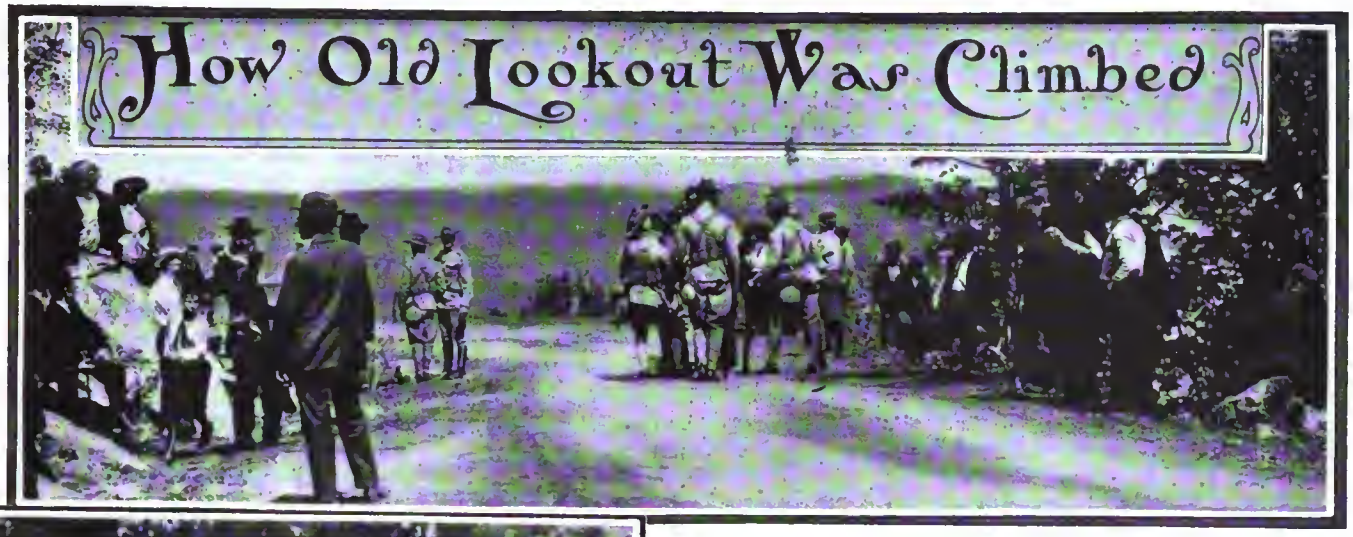
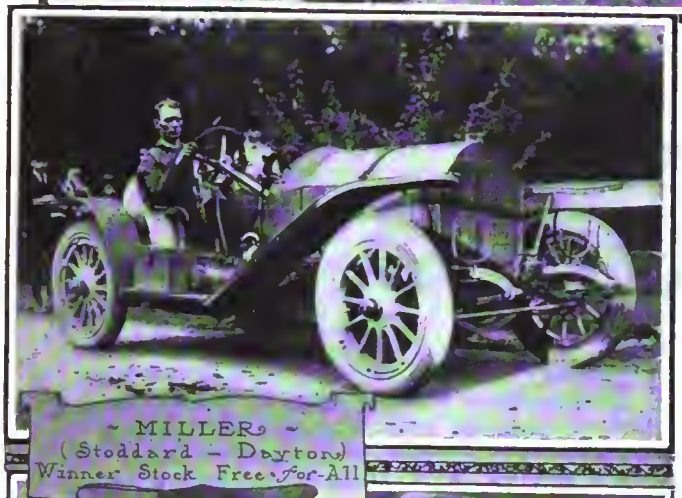
How Old Lookout Was Climbed





~ MILLER ~
(Stoddard - Dayton)
Winner Stock Free-for-All

STRANG and CHEVROLET
(Buick)
Fastest Performers

~ TUTTLE ~
(Stoddard - Dayton)

CHATTANOOGA, TENN., April 22.—Old Lookout Mountain, famous from Civil War days and known to the entire world, was conquered to-day by the men who drive automobiles and motorcycles. Yes, and more than conquered, for the cars ascended to the top of the mountain at a speed of from fifty to sixty miles per hour, rounding sixty-five turns throughout, and with grades that at times ran 30 per cent.

Fifty thousand people watched the climbing, watched for death round the "Flatiron," at the "Letter S," the "Double Letter S," the "W" turn, the "Serpentine" and the "Bridge of Fear." Some one made the trip earlier and named the points, and some one did the work well, for the names hardly convey the full meaning. The course is tortuous, the course is hard, the grades are steep, the road is none too wide at present, and none too safe.

Lookout came as a surprise to a lot of people who wanted to enter. Many came first, tried the course and backed out. Others came, saw and conquered in the end. Croakers said that deaths would result from the ordeal, but none occurred, and, therefore, the shouting of those who had the nerve to tackle the event and who won out.

To climb Lookout the start is made on the level at a point where the Southern Railroad is just constructing a road to go right through the mountain itself. The proposed bridge provides abutments that are excellent for sight-seeing. The road starts right up and goes past some splendid residences that are located at the foot. The grade is exacting and takes the wind from a few cars. Then come a lot of turns, serpentine in their way, and, suddenly, after passing along a bluff with Chattanooga in the distance, the car is driven to about as pretty a letter "S" as may be found. Many of the bluffs have been cut away to widen the road. One turn succeeds another, and each has new fears. No stretch is long and every turn has its problems. Suddenly the finish comes, also on a turn, and then the driver gives thanks that he has reached his destination; while the passenger: well, he just gets right down on his knees and talks of fate.

It all looked dangerous and had every one of the fifty thousand spectators who traveled up the hill to watch the cars go up taken a similar course of instruction, as did the writer as a passenger with Strang. the real drive would have aroused their interest to a greater extent. As it was these thousands picnicked along the course and waited patiently for each competitor to go by. The results had to be learned from the daily papers of the following morning. None on the hill learned the real time and each driver was cheered in turn, including the motorcycle men, who did the jumping-jack act as they drove their machines up the grades and over the rough going at from forty to fifty miles per hour, and at times faster.

Bert Miller and Harry Tuttle, with Stoddard-Dayton cars, were active competitors of the Buick, Locomobile and other entrants throughout the contest. Miller won out in the free-for-all stock car contest, and lost another event in all probability

for the reason that the timing tape was struck so hard when he made a flying start that it failed to record. This timing arrangement was a novelty. A white tape was stretched across the road about three feet from the ground. The cars struck the tape and released a gong which rang and was heard through the telephone at the top of the hill.

When Miller made his start in the seventh event he simply flew, and it was claimed made faster time to the bridge, about three miles up, than did any one else. From the start this bridge could be seen, and watching for the cars at this and other points as they could be seen in their ascent caused added interest at the start. Miller, after having started, could not be stopped, and so completed his daredevil effort without being timed. He demanded another trial and it was not given. His time for the eighth event, the stock car free-for-all, was doubled; in other words, being allowed for the seventh event. It brought him victory for that event, but in the free-for-all Strang and the Buick won out in 6:39 4-5.

Chevrolet negotiated the hill in 6:30 2-5 for the 4.9 miles, and this time was made at dusk. The honors for the fastest speed went to the daring French-American driver, whose daring was never to be questioned as he hurled himself at the turns, one after the other, in the fast gathering dusk, fairly pushing the returning populace off the course. The drive of the Frenchman was noteworthy, and drew admiration on all sides, especially as he had been up against the hardest sort of luck. Twice he had accidents, once a broken wheel, and another time a blowout.

The accident to Louis Doerhoeffer in his Locomobile proved a wonderful escape, as he shot into the ditch in making the "Hairpin" and he and his mechanic were thrown out in front of the large crowd. The car was uninjured.

Strang won three of the events. Daring always, he came to look at Lookout Mountain, and after several trips said that he would make the journey so often that every step would be familiar. He did so, and his nerve was good, although to the stranger "within the ranks" his daring seemed insane. No hard luck attended him throughout the races, although he gave "fate" every opportunity.

It is now the intention of the Lookout Mountain Automobile Club to apply for a national sanction and put on a great contest for next October, when the road will have been greatly widened, the rough spots taken out and danger spots protected. To every intent and purpose Chattanooga will aim to put forth the best hill climbing proposition in the country. Nor is it the intention of Chattanooga to do things half way. This was indicated at this meet, when the State soldiery was secured to guard the course. The soldiers used red flags for danger and white flags to announce the coming of the cars.

In Chattanooga the banks and business houses closed and it was made a local holiday. One of the local residents said that not one in four people kept away from the hill, and this is seemingly a fair statement. Nor did the people tire of the long waits for the cars, these waits being unavoidable owing to the inadequate timing arrangements.

The rain which came Thursday night, and proved a deluge, prevented any thought of the two days of track contests, and these were postponed until next week. It is improbable that many of the drivers will return, as the teams are scheduled elsewhere. The summary of the climb is herewith given:

FREE FOR ALL STOCK CARS.

1.	Stoddard-Dayton	Miller	6:58 3-5
2.	Buick	Strang	7:15 3-5
3.	Thomas	Duffy	7:20 1-5
4.	Locomobile	Doerhoeffer	Failed to finish.

STOCK CARS LISTING AT $3,000 AND UNDER.

1.	Buick	Strang	6:39 4-5

STOCK CARS LISTING AT $2,000 AND UNDER.

1.	Buick	Strang	6:48
2.	Stoddard-Dayton	Tuttle	7:49 4-5
3.	Chalmers-Detroit	James	10:42 2-5

STOCK CARS LISTING AT $1,000 AND UNDER.

2.	Curtiss	Green	7:25

700-MILE RUN OF HARRISBURG CLUB COMES NEXT

HARRISBURG, PA., April 26.—With arrangements en route completed, and the last detail attended to here, the final week before the start of the 700-mile run of the Motor Club of Harrisburg finds the club members and the officials in readiness for one of the most important events to be held in the East this year. Next Monday morning the contestants will leave the capital of the Keystone State for the national capital, crossing spurs of the mountains, through historic country, and over various conditions of Pennsylvania and Maryland roads. For four days next week they will be moving over the country under strict rules, and with experienced management, so that a remarkable endurance run is confidently expected.

Authorities all along the route have become interested in the affair, starting right here with the donation of the principal trophy by Governor Stuart, and by his starting the first car on its journey. The town and city authorities and automobile clubs along the way have been planning an enthusiastic reception, some of the places having dispensed with speed laws for the day, in case the tourists wish to show them how fast they can travel, and constables and police have been instructed to keep the streets clear. Maryland has even waived the privilege of license fees, and a government official will check the cars as they arrive in Washington. The second day the cars will return to this city via Baltimore; the third they will go up-State to Wilkes-Barre, via Sunbury and Williamsport; and the fourth they will return via Stroudsburg, Delaware Water Gap, Easton and Reading. In addition to the Governor's trophy, there are two others of value in the respective classes, one given by the Board of Trade, and the other by the *Patriot*.

The entries have been arriving in good numbers, and it is probable that there will be 25 or 30 starters, among whom are a number who have taken part in important national events. Walter C. White will make his first appearance in competition since his accident at Cincinnati; Tom W. Berger will have a six-cylinder Oldsmobile with 42-inch wheels; C. S. Carris will be at the wheel of a Franklin; Robert Morton with a Pullman delegation; and a number of private owners are also taking part. The complete entry list has not as yet been announced. The rules provide intermediate checking stations, with a definite time schedule, observers to be carried on all cars, and penalties for adjustments, repairs and replacements. All working parts, such as bonnets, battery boxes, coils, etc., will be sealed, and technically examined at the conclusion of the run.

The officials include such experienced men as R. H. Johnston, of New York, who is the referee; J. C. Kerrison, of Boston, as starter; David Beecroft, of Chicago, as chairman of the technical committee, and J. Clyde Myton, of Harrisburg. The immediate arrangements have been in charge of W. R. Douglass, the club secretary. Dr. J. R. Overpeck is the official pilot, and he will see that the confetti is scattered each day.

Automobile Gasoline and Other Available Fuel

Part III

By Thos. J. Fay

BESIDES the volatility of automobile gasoline the viscosity, and some of the other properties of the fuel will be worthy of discussion. Considering that the relation of air to gasoline in the mixture should be held at a constant ratio, if the best mixture is to be realized, it follows that the viscosity of the fuel should be a constant if the orifice through which the gasoline flows is some one fixed size, which viscosity can only be so if the temperature is held at a constant level, and if the fuel is fixed, as to its composition and in gas form.

The viscosity of gasoline increases as the specific gravity advances, so that trouble of this nature will augment as the fuel becomes inferior in character, assuming that poor fuel is represented by the heavy fractions of the distilling process. Taking "octane" as a standard to go by for the time being, the density of which is 0.707 specific gravity and the effect of viscosity will be about as follows:

TEMPERATURE IN DEGREES CENTIGRADE.					
10	15	20	25	30	35
Relative Viscosity Considering Temperature Only.					
Unity	1.073	1.145	1.212	1.270	1.225

An inspection of the above relations will at once disclose the reason why gasoline will be deficient in a carbureter of the nozzle type, when the temperature is low, if the adjustment is made for the right fuel relation when the temperature is high. For anything like good results, it is necessary to adjust the nozzle at a fixed (middle of the range) temperature, and the same should be a good average of the prevailing range of temperatures. In the Winter time, when the temperature is low, the nozzle should be with a larger hole (orifice) than will be required in the Summer time when the prevailing temperature is higher. At all events there is no one size nozzle that can be regarded as right for all degrees of temperature, and this is one of the every day troubles that autoists have to cope with, many of whom do not well understand why their motor will run to their entire satisfaction a part of the day, and not run well some other part of the same day.

In the carbureters using a needle-valve in the nozzle, an attempt is made to get away from this very trouble, but it rarely happens that the needle-valve as usually made is so designed that it will allow of the fine adjustment which is an absolute necessity, assuming that the remedy lies in a means for altering the flow of gasoline, from time to time, as the state of the weather would seem to require. It is even a question, that has never been adequately discussed, as to whether the needle-valve in the nozzle is really of any practical value. If it (as a device) is likely to add more trouble than it will cure, it is not a good contrivance to use. In some cases the needle-valve gives a great amount of trouble, and while it is possibly true that the difficulty might be done away with, the fact remains that it is not, and in practice, to deal with the existing conditions is a necessity.

Preheating Is One Way Out of the Trouble.—Heating the air as it leads to the carbureter is of advantage in certain ways, since it enables the gasoline, in globule form, to reduce to vapor, in the manifold to some extent, at any rate, rather than to have the globules enter the cylinders, there to form coke, and to be vaporized under conditions that can not be regarded as the most efficient. This heated air, however, will not compensate for changes in viscosity of the liquid, as it is sucked through the nozzle. The only way that the ills of viscosity can be eliminated is to heat the liquid gasoline, in the bowl of the carbureter to some fixed temperature, as is done in some cases, by water-jacketing the carbureter and allowing hot water, from the water jacket of the motor cylinders, to circulate through the same, which water should be at a constant temperature.

There is one trouble about this, but it is the lesser of the evils, since, while the water will be a little hotter than is necessary for the purpose, even so, it is possible to so contrive that the surface available will be within striking distance of the requirements. It is not desired that the gasoline shall be heated in excess of certain needs; indeed, it is something of a disadvantage to utilize more heat than the actual demand. On the other hand, it takes quite a little heat to boil gasoline, and the right place to apply the heat is to the liquid, rather than to the mixture, after it leaves the bowl of the carbureter. True, in the case involving the use of the gas tank, in which the gasoline is reduced to vapor before it is allowed to enter the mainfold at all, these vaporizing troubles are handled in the right way, in that the heat (taken from the exhaust products of combustion) is applied to the liquid gasoline in a manner sufficiently direct to serve the purpose. In this case the air drawn in is heated by contact with the surfaces of the heater, and the rich mixture should be quite free from liquid fuel. In actual practice this method shows enough economy to indicate that the reasoning is good, and that heat should be applied to the liquid; moreover, the idea is in accord with the dictates of logic.

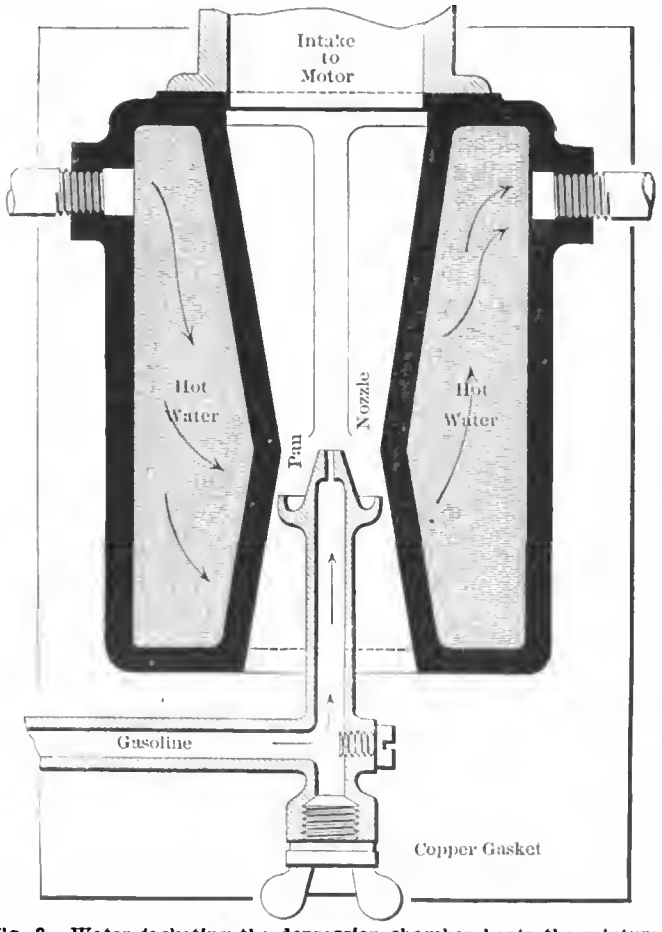

Fig. 8.—Water-jacketing the depression chamber heats the mixture instead of the liquid gasoline.

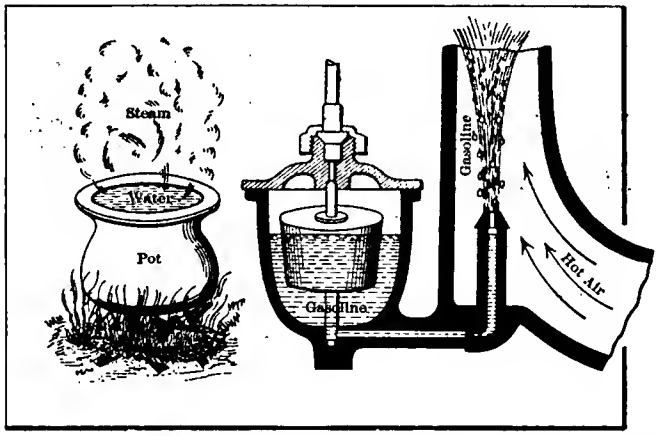

Fig. 7.—When water is boiled, a fire is built under the pot; this is the right way to boil gasoline.

The specific heat of air is taken at the low value, for the purpose of putting the error on the safe side, if one there happens to be. There is some question as to the air being at a constant volume in this service.

SPECIFIC HEAT OF GASES AND VAPORS AT A CONSTANT PRESSURE.

Substances.	Specific Heat for Equal Volumes.	Specific Heat for Equal Weights.
Steam	0.2989	0.4805
Oxygen	0.2405	0.2171
Nitrogen	0.2368	0.2438
Hydrogen	0.2359	3.4090
Carbon dioxide	0.2935	0.1952
Carbon monoxide	0.2370	0.2450
Air	0.1689	0.2375

SPECIFIC HEAT OF LIQUIDS AT TEMPERATURE OF MAXIMUM DENSITY.

Substances.	Specific Heat.
Water	1.00
Gasoline	0.50

NOTE.—The specific heat of gasoline depends upon its composition, specific weight, etc. The figure given is an approximation.

If the latent heat of evaporation of gasoline is taken to be 210.1 B.T.U., which figure will change, as the density of the fuel changes, it will be rendered apparent that a vast amount of vapor will have to be handled, per heat unit absorbed. If a gallon of gasoline weighs say, 5.9 pounds, and if it is assumed that a car will travel 11.8 miles per gallon, at a mile per minute, the gasoline consumption will be one-half pound per minute. This is rather a high rate of consumption of fuel, but there are cars that even exceed this, so that it is not a stretch of the imagination to use it as an illustration. On this basis, 105 B. T. U. of heat will have to be transferred to the liquid gasoline in order to evaporate it, during each minute of time. If water is used, and if the heat transfer absorbs from the water the requisite number of heat units, with a drop in temperature of the water of 20 degrees Fahrenheit, the amount of water required for the purpose will be:

$$w = \frac{105}{20} = 5.25 \text{ pounds (approximately) per minute.}$$

The reverse of this lies in the following:

B.T.U. = w x t = 5.25 x 20 = 105

when,

w = quantity of water in pounds,

t = change in temperature of the water in degrees Fahrenheit,

B.T.U. = thermal value in British thermal units.

If the specific heat of air is taken to be 0.1689, which is the right value for a constant volume (at a constant pressure the specific heat of air is 0.2375) the weight of air required to do the work that can be done by 5.25 pounds of water, will be:

$$a = \frac{5.25}{0.1689} = 31 \text{ pounds of air per minute.}$$

This is on a basis of 20 degrees Fahrenheit change in temperature, as was considered in the case involving water. The weight of a cubic foot of dry air at 72 degrees Fahrenheit is 0.0747 pounds, and if this weight is taken for a basis, the following will hold:

$$c = \frac{31}{0.0747} = 415 \text{ cubic feet of air per minute.}$$

If a motor with six cylinders is considered, and if the bore and stroke are taken at 4½ inches, respectively, the cubical displacement will be 248 cubic feet per minute per 1,000 suction strokes, so that there is not enough air for the purpose, considering all the air that can be used in the cylinder in view of displacement, and, unfortunately, all the air will not brush against the walls. Indeed, but a small part of it will be available to absorb heat from the walls, particularly in view of the presence of an auxiliary air valve, which allows the major portion of the air to by-pass the depression chamber in the average carbureter. In any case, the air is not enabled to heat the gasoline excepting as it leaves the nozzle, and the time allowed is far too short to assure results.

As for the cars in which no means are provided for heating the gasoline, it is highly improbable that very much of the same is vaporized before it enters the cylinders. They properly represent the school of design, in which it is claimed that it is a matter of no moment as to how the gasoline is vaporized, and that the results are good enough when the fuel is vaporized in the cylinders instead of outside.

For the cars using hot air it will be proper to remember that, the increase in temperature assumed, *i.e.*, 20 degrees Fahrenheit, is a fairly low value, and some of the trouble would be eliminated were the air to heat up more. On the other hand, there is small chance of all the air reaching a higher temperature, in actual practice, with the heating equipment used, and the glaring

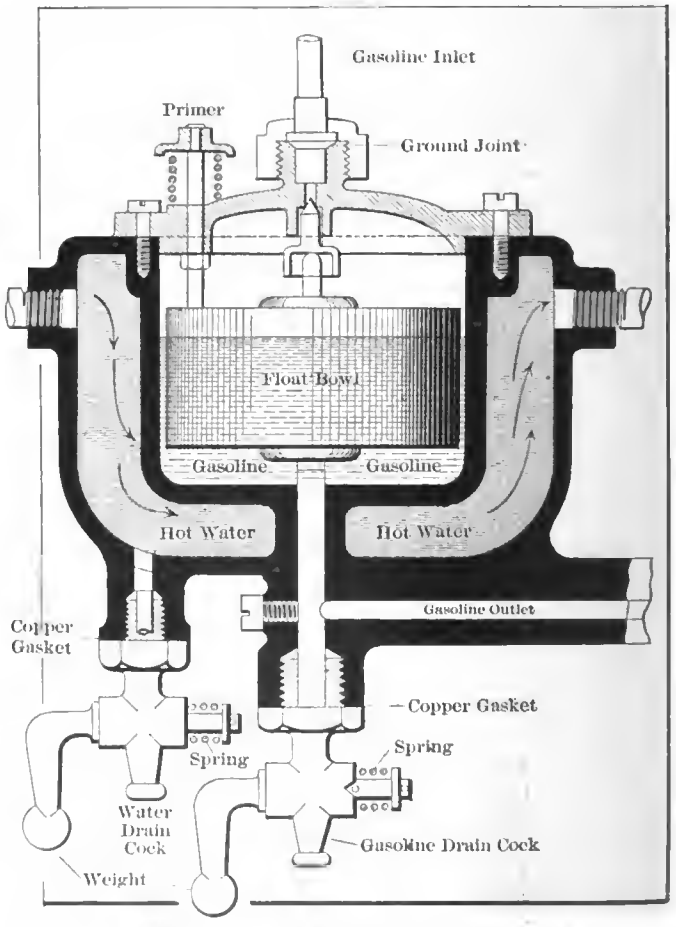

Fig. 9.—To heat the liquid, a water-jacket is placed around the float-bowl, in the manner as shown.

fact is rendered apparent, viz., the liquid gasoline is not reduced to vapor, excepting for a part, by the heated air, as it passes through the depression chamber, by the nozzle, en route to the cylinders.

The illustration is not sufficiently refined to take into account some variables as (a) the effect of diminishing the pressure, below the atmospheric, in order to induce the air into the cylinders, and to suck the gasoline out of the nozzle of the carbureter, (b) the presence of gasoline in the mixture, which must displace air. But these are all matters of small moment since they merely augment the trouble by a small percentage in that the amount of air will be less than the piston displacement represents.

The real story lies in the inability of the air to furnish an adequate amount of heat to completely vaporize the gasoline, and as a result, the gasoline must enter the cylinders, in liquid form, before it is vaporized, and since the cylinder temperature is at the "coking" point, some of the gasoline must form coke, which is a great disadvantage in practical work.

The real source of trouble then, is not the cylinder lubricating oil, but in gasoline instead, due to the very fact that the means of "boiling" the gasoline, to make vapor, does not afford enough heat to do the work outside of the cylinders, and as the temperature inside the cylinders is that which will deposit carbon out of the liquid gasoline, theory and practice are in full accord, excepting that the practical result is not wanted.

In Boiling Water Put the Fire Under the Pot.—To make steam it is necessary to boil water, and it would be regarded as a strange performance were anyone to apply the heat to the steam instead of to the water. Vapor of gasoline is no more nor less than the product of boiling gasoline, and the best way to produce the vapor is to boil the liquid, just as is done with water. Fig. 7 shows the way in which steam is made, in which a fire is built under the pot. The rest of the process is too well understood to require further discussion. A second figure in the same illustration also shows how gasoline is handled in automobiles, and it looks a little strange to apply the heat to the "spray" as it spouts out of the nozzle, in contrast with the pot of water along side of it, unless it is conceded that the old-fashioned way of boiling liquids is wrong.

Practical Devices Used in Heating Fuel.—If heat is applied to the mixture only, rather than to the liquid, Fig. 8 shows the manner in which the water jacket is contrived, in which the water is entered at one (convenient) point on the diameter, near the top of the casting, and in view of ribs that are made to serve as baffle plates, in the manner as shown by dotted lines, the water is forced down, and around, to the water outlet on the diametrically opposite side of the casting. The amount of heat that will be taken up by the gas will be limited, for the reasons as given, amongst which, as stated, the specific heat of the gas is a rather low value, and too, the surface available is restricted. True, the low specific heat of the gas is assurance that it will heat up readily, without absorbing much heat from the water in the jacket. On the other hand, the heat requirement is a definite quantity, and unless this full amount is taken up by the gas, the same will be with entrained liquid, which is not wanted, especially as carbon is likely to form in the cylinders if the liquid is not completely vaporized before it enters the combustion chamber of the cylinders, in the motor.

Water-Jacket Should Be Around the Float Bowl.—In case it is desired to take advantage of the benefits to be derived from heating the liquid gasoline, rather than the gas mixture, it is then that the plan as depicted in Fig. 9 will be the preferable one, and as shown, the water jacket is around the float-bowl, into which the gasoline enters on its way from the fuel tank to the motor. As will be observed, the water enters at the top, and if a system of baffle plates are provided, as they should be, the water will flow down, thence up, and out on the opposite side of the bowl. In view of the increased ability of the liquid gasoline to absorb heat, and in further view of the slow rate at which the gasoline flows out of the bowl, which is a condition that does not exist in the case of the vapor, the requisite amount of heat is assured,

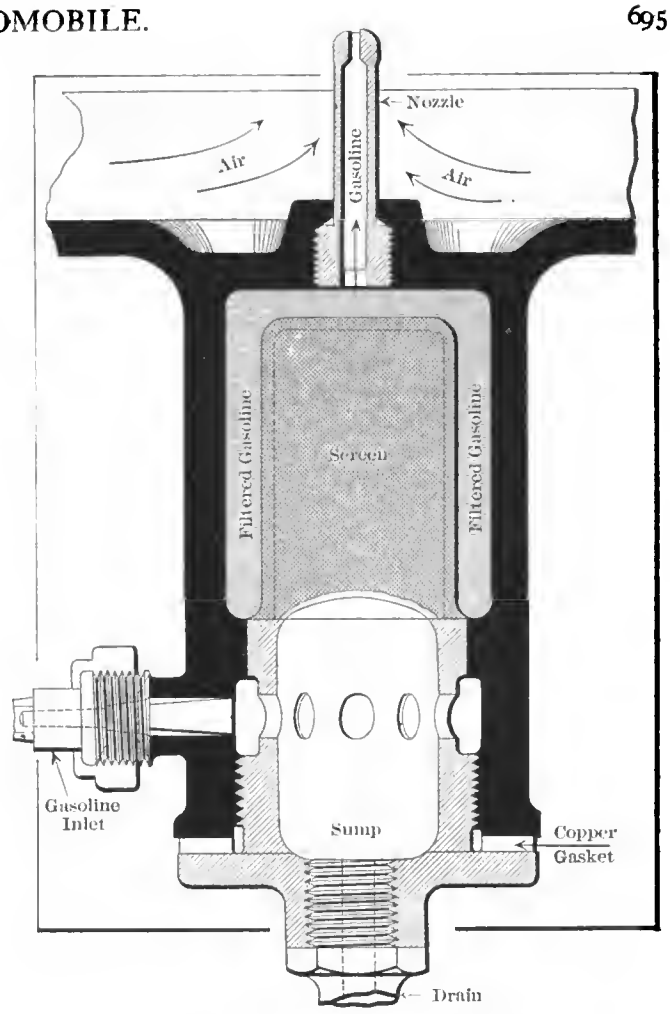

Fig. 10.—Illustrating a strainer to be placed between the float-bowl and the gasoline nozzle, in the depression chamber.

even if the difference in temperature between the water and the gasoline is not so very great. In general, the difference in temperature should be about 150 degrees Fahrenheit, and this is quite enough for the purpose, with, perhaps, a good margin.

The construction shown is more by way of a diagram, in so far as the bowl is concerned, and the float is of the direct acting genera, which is not the only kind used in practice. As will be observed, however, the needle is separate, and it is therefore self adjusting, so that if the float gets out of alignment, it will not of necessity cause the needle-valve to leak. Leaky valves cause much trouble in practice, due to the use of inferior material in some cases, and to the form of construction, in which the system gets out of alignment, or sticks. For the needle, it is believed that German silver is the best, although it is difficult to procure. which is the main reason why soft brass rod-stock is more often than not used for the purpose.

The float should be of "spun" copper, rather than of cork, and if cork is used it is a moral certainty that it will lose its buoyancy before very long, in actual service. If the float is of copper, it can be adjusted to the conditions, without resorting to the use of means for changing the adjustment at will, and in this practice there is nothing to shift, so that, once the adjustment is right, it will stay so. It is not uncommon, in connection with carburters, to observe that the cocks are of the sort usually found on gas fixtures and on other work in which the ills of vibrations are not figured upon. For carbureters it is scarcely to be expected that the ordinary form of cock will do the work without giving a certain amount of trouble, and the form of cocks shown are certainly better, in that they are provided with a spring-locking device, so contrived that the cock can not jar loose. The lock consists of a pin in the stem of the valve which engages a nick in the housing. When the valve is turned the spring compresses enough to allow the pin to slide out of the

notch in the housing without any trouble at all. The crank on the stem is also weighted, and the weight hangs downwards when the cock is in the closed position. This is an additional safeguard that is of good value, and the cost is really nothing extra. If all cocks are so devised, it is then that the autoist can see, at a glance, if the cocks are opened or closed, and in the dark, it is only necessary to feel the position of the crank on the cock, to be able to tell if it is opened or closed.

In the future, it is a moral certainty that the fuel question will become sufficiently acute to require that every known means will be provided, in order that the gasoline may be quite completely vaporized, and with this contingency in mind, it may be that the question of the water-jacket is one to be discussed on a basis of jacketing not only the float-bowl, but the depression-chamber as well. There can be no possible objection to the extension of the jacket to include the depression-chamber, especially if, in the course of events, fuel becomes less volatile than it is at the present time, although it is a sad condition to contemplate. Should it be desirable to jacket around the mixture, as well as around the gasoline in liquid form, it will be the right plan to take advantage of the methods shown in both Figs. 8 and 9, combining them for the purpose.

A Strainer Should Be in the Gasoline System.—Considering the diameter of the nozzle orifice, even in the cases involving the use of very large motors, it is easy to understand how a little slime, or hard paraffine, will serve as the nucleus for further accumulations of such matter as will be found in gasoline, and Fig. 10 shows a strainer such as should find lodgment in the system, between the float-bowl and the nozzle. As will be observed, this device, as shown, requires the liquid to enter to the inside of the strainer, the object being to assure that the accumulations will be withdrawn, with the strainer, when the same is removed for the purpose of cleaning. It will also be observed that there is plenty of room in the well for the strainer, and a good space is allowed between it and the walls of the housing. In some of the earlier types, it was the custom to afford but little room between the walls and the surface of the strainer, with the result that jelly formed readily, and when the strainer was removed for the purpose of cleaning the jelly failed to come out, but after being loosened up it would float up to the nozzle and cause stoppage of the fuel at frequent intervals until it became an argument in favor of a design such as would not allow the jelly to collect on the inner wall of the well.

Why Hot Air Will Not Best Serve the Ends.—It is really necessary to heat the liquid gasoline, just as it is proper to heat water to cause it to boil. It would seem to be just as good practice to try to heat steam to make the water from which it is made, boil, as it is to heat mixture in the intake of the motor, in order to cause the liquid gasoline to boil off as it oozes out of the nozzle. Hot air, drawn in through the primary air-take, while it does afford a measure of benefit, is representative of a most indirect way of doing that which can be done directly. True, there are ingenious devices in vogue, by means of which the heat is applied with good effect, particularly when the gasoline is of a desirable quality. The time is fast approaching, however, when even a fine display of ingenuity will fail, in a measure, at any rate, to deliver enough heat to the fuel, by any indirect process, and it is believed that the water-jacket method will find many converts.

(To be continued.)

NOVEL AND PRACTICAL SYSTEM OF CAR RENTING

THE majority of garages rent an automobile by the day rate or hour rate alone, the usual charges for the day being from $25 to $35 for a five to seven-passenger car, whether the customer uses the car a full day or not. The length of the day varies also, some garages reckoning eight hours to the day, while others reckon twelve hours. No record of mileage is kept, and should the car need repairing on the road no deductions are made from the charge. Hour rates vary from $3 to $5, and at hour rates the customer is also deprived of the use of the car when repairs are being made. It is customary to either collect the charges in advance or have the customer pay the driver on giving up the car. Under these circumstances charging by the day or hour is unfair to both the customer and the garage, in charging the former for service he does not get, and in putting the latter at the mercy of an unscrupulous driver, who can pocket a proportion of the hire by claiming that part of the time was employed in repairs, or that the customer discharged the car sooner than he expected. Again, if no mileage record is kept, the profit or loss on each car rented is difficult to determine.

To give fair treatment to the customer and at the same time to protect the garage, the Central Auto Station Company, Pittsfield, Mass., rent their cars out on a mileage or hourly basis, the maximum total prevailing. The cars are fitted with clock, and season and trip odometers, and before leaving the garage the time and mileage odometer readings are entered on a rental slip, along with the name of the car and the driver's and customer's names. If the car is run steadily, the mileage rate as indicated by the odometer of 25 cents a mile is charged, but if the car is kept waiting, the hour rate of $3.50 prevails. Should repairs be necessary on the road, the elapsed time is deducted from the hour rate. When the trip is finished the odometer and clock readings are again taken at the garage and entered on the rental slip, a specimen slip being shown in the accompanying illustration. The bill is then made out from this slip and delivered to the customer. It will be seen that the route is also marked on the slip, and that the slip acts as a check on the driver and customer, and is conclusive proof in case of a dispute. The system is working with great success, and is well worth universal adoption by concerns desiring to embody the latest methods.

Preparing a Car Systematically for the Road

By D.R.Hobart

SYSTEMATIC procedure in preparing a car for the road and in attending to its wants during the trip will result in the necessary attentions soon becoming second nature to the operator, with the result of keeping the car in good condition. It is a well-known fact that most of the trouble occurring to automobiles come from negligence, outside of careless driving. Given a careful driver and proper attention, there is no reason why the life of a motor-driven vehicle should not be measured in years instead of months, as is too often the case.

Commencing Operations, Filling and Oiling.—The autoist, when commencing his preparations of the car for the road, should start by filling the water tank, which in most cars is combined with the radiator, with absolutely clean water.

After doing this, the pipes carrying the water to and from the radiator should be examined for leaks and the grease-cup on the pump screwed down one turn. The fan-belt should then be tested for tightness and the fanshaft oiled.

Then, beginning with the starting crankshaft and the front springs, and moving toward the rear of the car, every oil cup and hole should be liberally fed with oil and every grease cup screwed down one turn, not forgetting the gear shifter shafts and the brake shaft. As the oiling progresses, every moving part of the mechanism should be inspected, the steering linkage being tested for looseness, the clutch operated to "work in" the lubricant, and the spark and throttle levers and the pedals worked to and fro to loosen them up and distribute the oil. It would be well for the autoist to have a plan-view of the car with all oil cups and grease cups marked so as to facilitate the oiling operation.

Lubricating Oil Is Infinitely Cheaper than Worn and Broken Machinery.—Should a nut or bolt be found loose during the oiling, it should be tightened at once and not left until later on, as it may be forgotten, with disastrous results. To most people the number of places to be oiled seems too great, but as a matter of fact the complete oiling of a car takes but a few minutes and more than repays for the time spent in the longer useful life of the car.

Examining Tires and Springs, and Cranking.—The tires should be examined for cuts and weak spots, and if likely to cause trouble on the road should be changed. A glance at the springs will show if any leaves are loose or broken, and the nuts holding the spring clips should be tried with the fingers for slackness.

The gasoline tank can now be filled, the spark retarded and throttle partially opened, and the gear-shifter lever placed in the neutral position. The hand brake should be put on and the motor turned over by the starting crank.

In cranking a motor the autoist should grasp the crank handle with the left hand and hold on to the right dumb-iron with the right. He is thus enabled to exert more power on the handle, and in case of a back-fire will not be injured, the fingers being merely thrown open as the handle moves downward. When a back-fire occurs when cranking with the right hand, the autoist is lucky to escape with a wrenched arm or a cut or bruises, as the position is awkward and the body is out of balance.

With battery ignition the spark should always be retarded on starting the motor, but with magneto ignition, which is in use on a large majority of cars to-day, the spark is fixed, or, if not, should be somewhat advanced.

Note Action of Motor and Lubricator.—Having started the motor, the autoist should listen for any unusual sounds while it is running and also closely watch the sight-feeds on the lubricator, adjusting them if necessary.

If the car is likely to be out after dark, the acetylene generator should be provided with carbide and the lamps filled.

If a gas tank is used instead of a generator, the autoist should see if the pressure gauge indicates that there is sufficient gas in the tank for the trip, and, if not, the tank should be replaced by a charged one.

In connection with filling the lamps it would be well to form the habit of wiping the tail-lamp glasses and the license-plate with a cloth, as these are usually neglected and become obscured by dirt, and may subject the autoist to arrest for not having a rear light or an illegible license-plate.

Trying Out the Car.—The autoist should now take his seat, and, withdrawing the clutch, place the shifter lever in the position for first speed, release the brakes, and start the car by engaging the clutch gradually.

While the car is moving the brakes should be operated, first the hand brake and then the foot brake, and if any adjustments are needed they should be made at once. A trial of the brakes with the car running is more valuable than a number of trials with the car at rest.

If the gear shifter lever does not work properly or the clutch slips, the fact will be indicated and adjustments made on the spot, saving the autoist trouble and humiliation on the road.

Easy Means of Remembering Procedure.—If the above method of procedure is followed, it will be surprising what a short space of time will be consumed in preparing the car. As an aid to memory, the words WON'T GAT can be used, the initial letters of words describing the various operations being employed, thus:

Water.
Oiling.
Nuts and bolts.
Tires.
Gasoline.
Acetylene.
Trying-out.

ITALIAN INSTRUMENT FOR MEASURING CYLINDER BORES.

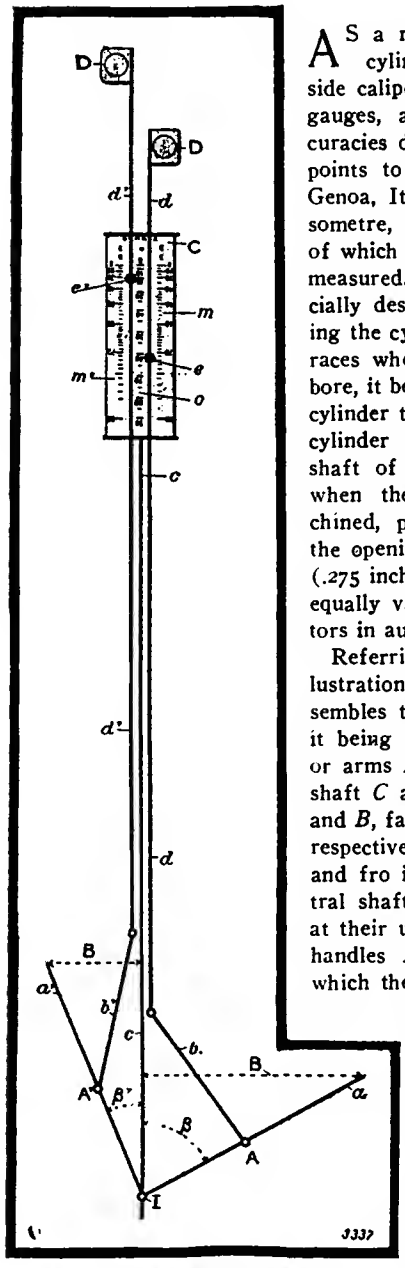

Diagram of Alesometre, Showing Operating Scheme.

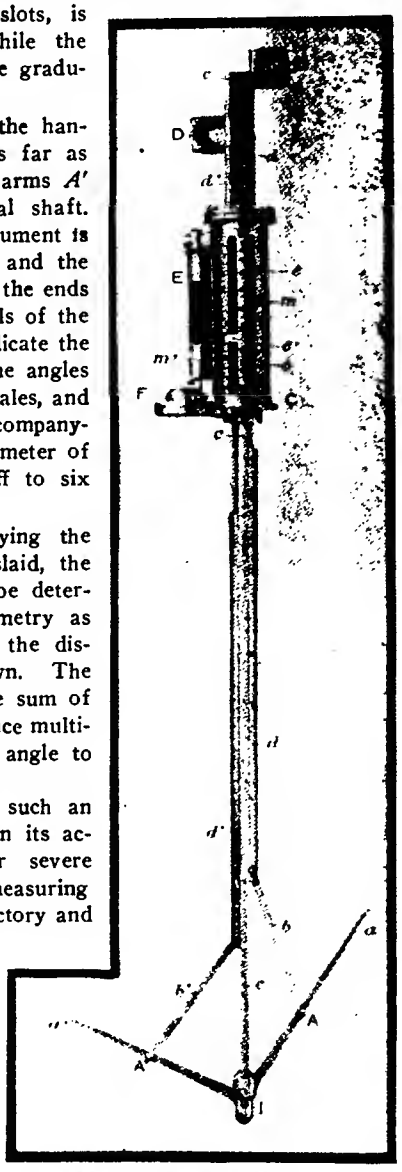
AS a rule the bore of a motor cylinder is measured with inside calipers, or in some cases star gauges, and to prevent the inaccuracies due to applying the caliper points to a scale, M. Paradis, of Genoa, Italy, has invented the alesometre, an instrument by means of which the bore can be accurately measured. The instrument is specially designed for use in measuring the cylinders of motors used in races where the classification is by bore, it being readily inserted in the cylinder through the opening in the cylinder head through which the shaft of the boring tool projects when the cylinder is being machined, provided the diameter of the opening is not less than 7 mm. (.275 inch). It is obvious that it is equally valuable for use by inspectors in automobile factories.

Referring to the accompanying illustrations, the instrument resembles the frame of an umbrella, it being provided with two "ribs" or arms A' A pivoted to a central shaft C and controlled by links B' and B, fastened to sliders D' and D respectively. The sliders work to and fro in grooves cut in the central shaft and are reduced in size at their upper ends and fitted with handles D' and D, by means of which they are moved by the operator. A cylindrical casing C is fastened to the shaft and is slotted to allow pointers E' and E to move with their respective sliders when the handles are operated. The cylinder is graduated on its front face, the positions of the pointers indicating the distances B-B in the diagram and also the angles β' and β which the "ribs" or arms A and A' make with the central shaft. The graduations are placed upside down so that the operator can read them by slightly inclining his head, and not disturbing the adjustment of the instrument. Two spirit levels E and F are fitter to the cylinder, one for vertical and the other for horizontal use. The central scale, between the two slots, is graduated in degrees, while the outer scales M' and M are graduated in millimeters.



The Paradis Alesometre in Operating Position.

To use the alesometre, the handles are pulled upward as far as they will go, folding the arms A' and A against the central shaft. The lower end of the instrument is inserted into the cylinder and the handles pushed down until the ends of the arms touch the walls of the cylinder. The pointers indicate the distances B B, and also the angles β' and β directly on the scales, and by referring to a table accompanying the instrument the diameter of the bore may be read off to six decimal places.

If the table accompanying the alesometre should be mislaid, the bore of the cylinder can be determined by simple trigonometry as the angles β' and β and the distances B' and B are known. The bore would then equal the sum of the products of each distance multiplied by the sine of the angle to which it corresponds.

It is doubtful whether such an instrument will long retain its accuracy under the rather severe usage usually given to measuring instruments both in the factory and at the track. It will be noticed that there are five joints in the instrument, and no provision for the inevitable slackness is made, so that measurements will sooner or later become unreliable. As the graduations are only in millimeters, it will be impossible to make as accurate measurements as with micrometer calipers, and cylinder diameters slightly over or under the even millimeter cannot be detected with accuracy.

IRREVERSIBLE STEERING EXPLAINED.

The question is often asked, what is irreversible steering? This cannot be explained in a word. The first form of steering arrangement consisted of a series of arms and linkages. In extreme cases it was possible to so place the steering lever that road obstructions would turn the wheels out of their position, even against the driver's exerted strength.

The modern form of steering gear is such that this is impossible. The mechanism used differs from the old form. Moreover, it is self locking. The usual form of this is the worm, which, of itself, may not be forcibly reversed from the road end of the steering arrangement.

WHEN A LAMP GLASS BREAKS.

When the tail-lamp glass breaks, red tissue paper bought from a stationery or toy store can be substituted, the paper being either tied round the lamp with string or fitted into the frame which held the glass. As there is no head draught on the lamp, this "wrinkle" is perfectly feasible. If a sheet of paper such as is wrapped around butter can be obtained, it can be fastened on with wire after doubling it and greasing it, coloring with red ink or dye. This can be used for head and dash lamps also without coloring the paper, of course. A handkerchief can also be used, and if none are lost the glass can sometimes be held together by adhesive plaster.

Information for the Man Who Drives

Caring for Acetylene Lamp System.—As there is little night running during the winter months, the acetylene lighting system is more or less neglected, the generator being left with stale or partially used carbide in the chamber, and the residue being allowed to clog up the water port and the waste ports. The rubber lamp connections and gas-bag suffer also by deterioration as well as the burners and gas valves. For the proper maintenance of the system, strict cleanliness should be maintained at all times and the various parts should be examined and replaced from time to time as necessary. The results of neglect are seen every spring in lime deposits which have to be removed by means of a cold chisel, in porous connections and in clogged burners which resist the cleaning wire and necessitate the scraping of the burners. By following the accompanying directions, the automobilist can depend on having his lighting system in good shape whenever he desires to use it.

Care of the Generator.—The interior of the carbide chamber or basket is more or less in contact with the water distribution apparatus and the parts of both apparatus are liable to clogging by the formation of lime residue in the generation of gas. If this residue is allowed to collect, it will have to be removed with a chisel, which is a ticklish operation in a light construction like that of a generator, especially around the water valve or its outlet. Acids are sometimes used to remove the deposit, but as they eat the metal, their use should be prohibited. The basket and pot should be thoroughly washed out after each run with water, the water outlets being cleaned with special brushes, when these are obtainable, or by wires, removing all traces of lime. The water valve should be scraped and tested to see whether it seats properly, care being taken not to damage the valve or its seat in so doing. While the valve is dismounted for cleaning it would be well to see that its stem is straight and that it works with some ease in the threaded portion attached to the water chamber. The gas valves should be cleaned and should seat snugly, so that there will be no leakage past them. This applies also to the gas valves on the lamps.

The best position for the generator is on the runningboard just back of the change-gear quadrant, and sufficiently far out from the frame to allow a free circulation of air all around it. The generator will keep cool in this position and will perform its work to the best advantage when properly cooled.

The Much-Neglected Condenser.—When used at all, the condenser or its substitute is put off in some position where it becomes caked with mud and is almost forgotten until it is full and the lamps begin to flicker. Then the mud is cleaned from it and it is drained out. It should be placed so that it is close to the lamps, where it will catch all of the condensation from the gas going to the burners, and in addition any water that may enter the burners due to washing of the car. It should be emptied from time to time, say once or even twice a month, when the lamps are in regular use. The majority of troubles with acetylene lamps are due to lack of a condenser and to the use of too small metal tubing.

Regarding Tubing and Gas Bags.—Copper tubing is considerably used for piping the gas to the burners, but it is liable to erosion by the gas, and standard 1-8-inch gas pipe is better and lasts longer. The gas bag and rubber lamp connections should be kept clean and not painted, as is often done to correspond with the car, as paint rots the rubber, with the result that it is soon unserviceable and must be replaced. When the rubber is to be washed, only water should be used and the goods should be carefully dried before putting them in service again.

Care of the Lamp.—It goes without saying that the burners should be kept clear, wires being passed through the gas apertures and the air apertures at intervals. The burners should be unscrewed occasionally and blown through, and the interior of the burner body scraped clean of deposit. Outside of keeping the lenses and glasses bright and polishing the exterior of the lamp, there need be no other attention paid except to keep all joints and the bracket screws or nuts tight.

To Avoid Clutch Trouble.—One of the greatest sources of trouble for the novice lies in the clutch. This may be just right, it may be slipping or it may be what is called fierce. The second manifests itself in such pleasant situations as climbing a hill when, with the engine running at its highest speed and the proper gear engaged, the car starts to run backward instead of forward. Or on the level, with the engine racing and the high gear in, no speed results.

The last condition shows itself in the sudden jumping forward of the car when the clutch has been let in, or it may even be so severe as to shear off the bevel driving gear when used with studded non-skid tires or any form that will not slip easily.

To repair the first, look at the leather, if this is all in good shape with an apparently good surface, but has lubricating oil on it, wash the surface well with gasoline. It is not a bad idea to roughen the surface of the leather a little with a coarse file.

The harsh or fierce clutch is remedied by the application of a proper oil for this purpose. Castor oil is universally used and a good way is to soak the complete clutch in it over night. This will cure a case of harsh leather, but it may be that the trouble is only a lack of adjustment of spring tension. Usually there is an adjusting nut and a locking nut. Back off the latter and make an adjustment. Then tighten the lock nut to retain it. For the beginner, it is better to adjust a little at a time and make several successive jobs of it than to try to do it all at once. But always adjust it as soon as possible.

The Proper Care of Chains.—The owner or driver of a chain-driven car should learn very early in his driving career to care for the driving chains in a proper manner. While chains have been known to run an entire season without any care or additional lubrication, this practice is deprecated. To care for a chain properly, one should get into the habit of lubricating every so often and so time these intervals that they occur before the chain is in need of the oil. In addition to this regular lubrication, there should be some set time at the end of which the automobilist takes the chain off, cleans it thoroughly, and inspects it to detect faults.

A month is a good length of time for this, and an excellent way to proceed is to take the chain off and throw it into a pan of kerosene. In the morning, all of the dirt will have passed from the chain to the liquid and can be found in the bottom of the pan. Take the chain out and throw the liquid and dirt away. Then clean the pan and in it wash off all traces of the kerosene with gasoline. Having done this, hang the chain up to let the gasoline evaporate.

The chain then will be both clean and dry. Now inspect all rollers, links, rivets and bushings, taking note of any unusual wear as indicating by looseness or play. If defects are found, they should be remedied. Then, having the chain clean, dry, inspected and passed upon as O K, an excellent method is to soak it, or, better, boil it in a heavy melted lubricant. The best quality of beef tallow mixed with a little graphite is good. Many do not like the latter, in which case a high-grade oil may be substituted for the purpose.

COMPOSITION OF COMMERCIAL PETROLS.

By BERTRAM BLOUNT, F. I. C.

Since the modern automobile came into use the nature of the fuel has been a question of much interest, leading to many tests. Originally the specific gravity was measured with a hydrometer, but this was soon abandoned as valueless. Many drivers have a lurking doubt about the quality of their fuel and as soon as trouble crops out blame the petrol. In an endeavor to prove or disprove this, the writer purchased in London a number of samples of seven different brands, all in sealed cans. Thus it may be taken that it was such as the producers habitually make.

The samples were examined by the usual fractional distillation, and their specific gravities and those of their fractions were determined. In addition, a certain number were analyzed for sulphur, and one or more examples of each brand were burnt in a calorimeter. The results are shown in the table.

It is often supposed that the calorific value varies with different origin or quality, but in fact the variations are small. This refers to a given *weight* of the fuel; by volume there is a considerable difference owing to the different specific gravities of petrols. The calorific value stated in calories per liter and in B.T.U. per one-tenth of a gallon indicate this, and show that as long as petrol is sold by measure instead of weight an appreciable advantage is secured by buying the heavier grades, provided they can be burnt efficiently.

The determination of the calorific value was a matter of difficulty. A bomb calorimeter was used which, though easy to manipulate when solid fuels are burnt, needs special handling with a volatile liquid like petrol. In spite of the fact that there is an excess of oxygen at a pressure of 25 atmospheres, complete combustion was difficult to secure. Moreover, the explosion was so violent as to shatter the platinum cup in which the petrol was contained. After many trials the petrol was enclosed in a relatively deep cup provided with a celluloid envelope rising above the edge and contracted at the top so as to form a sack with a relatively narrow mouth. By this means the vapor was confined sufficiently to cause it to burn at a moderate rate and imperfect combustion and violent explosions were avoided. The percentage of sulphur in all cases is so small as to be without practical significance. The petrol engine is free from this drawback which occurs with coal.

The remaining figures are worthy of study. It may be noticed that the specific gravity of any given brand varies within comparatively narrow limits save in cases where there are two grades. The percentages distilling within limits are less regular, but the variations are moderate, and not greater than might be expected with a commodity which is of a very complex mixture.

Three of the brands present so general a similarity that they may be grouped and their average composition compared.

	Pratt.	Shell.	Carburine.
	Per cent. by volume.		
Below 100° C....	65.0	66.6	66.5
100 to 120° C....	24.8	23.9	23.7
120 to 133° C....	6.0	5.0	5.8
Above 133° C....	3.0	3.1	2.8
Loss.....	1.2	1.4	1.2
	100.0	100.0	100.0

The resemblance is sufficiently close to make possible a specification for petrol filled by all three brands, thus freeing the consumer from the obligation to buy any particular one and allowing that each may be employed as convenience may dictate.

The other brands differ too widely to admit of grouping, but comments may be permitted. Anglo "760," which has a specific gravity of 735-740, is in a class by itself. It differs from the foregoing in the small fraction distilling below 100 deg. Cent., and the middle fraction coming over at 100-120. The succeeding fraction from 120-133 is large, but the tailings (distillate above 133) are as small as those brands discussed.

Carless's "standard" is the lightest of those examined, 86.5 per cent. distilling below 100 and 98 per cent. below 120. Like Anglo, it stands in a class by itself, and is similar to the petrol of the days when .68 was desired and .70 was an upper limit. If fuel like this is desired a different specification is necessary.

TABLE SHOWING THE RESULTS OF AN EXAMINATION OF SAMPLES OF SEVEN DIFFERENT BRANDS OF PETROL.*

*Petrol is the English term for all petroleum products, suitable for use in internal combustion engines and is comparable with the word gasoline, extensively used in the United States, or the word essence, which the French apply to the engine fuel. The word petrol is a very logical one, being derived from the word petroleum, from which the fuel is obtained by distillation.

Letters Interesting and Instructive

CAR HARD TO START.

Editor THE AUTOMOBILE:

[1,852.]—I have a two-cylinder 1907 model which, after giving much good service, has begun to get freakish. It runs well at times, but overheats so badly that it is necessary to fill it with water every twenty miles. Also the engine is very hard to start. Can you suggest anything which will overcome this? G. H. G.

New York City.

Your machine is probably in need of a general cleaning and overhauling; carbon deposits in the cylinders, scale and mud in the cooling system will doubtless be found responsible for both the failings you mention. As in this car, the entire power plant is hung on the frame by bolts in the ends of the cylinders, it will be a somewhat lengthy process to take these off for cleaning, and a better scheme will be to use one of the decarbonizing fluids on the market. Fill the cylinders with this through the spark-plug hole, making sure that the compression cocks are closed, and let it stand over night. In the morning the greater part of the fluid will be found in the crankcase, whence it may be drained off, as well as through the compression cocks. Put plenty of oil in the crankcase before starting again.

The cooling system can be effectively cleaned with kerosene, which will loosen up the scale. The hose connections had better be removed, to be replaced with new ones, and the openings stopped with corks before pouring in the kerosene. This, too, should be allowed to stand over night. After the engine has been cleaned out in this way a new adjustment of the carbureter, effected by the air lever under the steering wheel, will probably be found advantageous.

WHY PNEUMATIC TIRES?

Editor THE AUTOMOBILE:

[1,853.]—Will you please inform me through the columns of "The Automobile" why the pneumatic tire is used on automobiles in preference to solid rubber?

A. B. LANGWORTHY.

Soldiers Home, Cal.

The pneumatic tire is used to secure a desirable spring effect, and to reduce the vibrations. The former is in addition to the usual body springs, which as yet are not perfect. The springs also absorb some, but not all, of the vibrations set up by the rapid passage of the car over road surfaces which are far from even. The pneumatic tire, properly filled with air, possesses the much-desired quality known as resiliency. The air-filled tire has the two additional qualities: first, yielding to or swallowing up small obstacles, and, second, obtaining a better grip on the road. The former is very desirable because it does away with much of the lifting up of the wheel in passing over obstacles. It therefore makes the car, so equipped, ride easier. The ability to take a better grip upon the road allows, in addition, greater speed than could be obtained with the heavier and less resilient solid tires. As to the weight, inflated pneumatics would weigh about one-third of the solids, so when reducing the weight as low as possible, why add this weight unless there are some advantages to counterbalance it?

On the other hand, the solid tire has a number of undeniable advantages, such as the freedom from punctures, and the attendant saving in worry. This is, however, being minimized by the use of demountable rims and tires.

AUTOMOBILE SCHOOLS.

Editor THE AUTOMOBILE:

[1,854.]—What good schools are there for learning the mechanism of the different makes of automobiles and the ways of operating and repairing them? How long are the courses and what is the cost?

Albion, N. Y. DAN BULLARD.

Aside from the correspondence schools, of which there are a number, you would probably get more from a school in which the practical workings were emphasized. If you are in a position to come to New York City, there are several excellent automobile schools here, one of which would doubtless suit you. The Y. M. C. A. maintains such a school at its Fifty-seventh street branch. The cost of the course at this school is about $50. It may be completed in either four or eight weeks. In the former case, there will be four shop periods of three hours each and two road lessons of one hour each, per week. In the longer course these are just halved, that is, two shop and one road lesson per week.

TO CORRECT A MISS.

Editor THE AUTOMOBILE:

[1,855.]—My car, a four-cylinder model, misses persistently in one cylinder, especially at low speeds. I have changed spark plugs, inspected the high-tension wire and adjusted the vibrator, but without results. The car has been in use for little over a year and is otherwise in good condition.

Brockton, Mass. PUZZLED.

Such a miss as you describe is as likely to come from an air leak into the inlet as from the ignition, and since you have gone over the latter so thoroughly it will be well to try the former. In case the cylinders are separate, or if there is a separate branch of the inlet pipe for each cylinder, the leak will probably be found where the pipe bolts on to the cylinders. A new gasket is the remedy. It is also possible that the leak may be around the valve stem. In this event a new valve stem guide should be provided. Or, if the valve guide is integral with the cylinder casting, it may be bushed.

TRANSMISSION TYPES AGAIN.

Editor THE AUTOMOBILE:

[1,856.]—Will you please inform me through the medium of "Letters Interesting and Instructive" what is the difference between the selective and progressive types of transmission? A READER.

Longmont, Colo.

The difference between the selective and progressive transmission is mainly a difference in the method of operating the speed changes. In the former the operator may select the speed desired and change to it at once without passing through any other speed. With the progressive type the continuous or progressive movement of the gear-shifting lever gives in succession the speeds from the lowest to the highest. In this form, if the low speed is engaged, and the high is desired, it is necessary to pass from low to second and then to high. If there are four speeds, from low to second, second to third, and third to high.

CYLINDER OIL TESTS.

Editor THE AUTOMOBILE:

[1,857.]—Would you kindly answer through "Letters Interesting and Instructive" what is one of the best ways to subject cylinder oil for an automobile to a fire test, and what is the requisite test for a good oil.

Independence, Kan. L. V. STANFORD.

There are really two parts to the fire test, as it is called. One is the test for flash point. This may be determined as follows: Take two pieces of glass of the same size and large enough to cover a small glass beaker. In one of them cut a couple of notches. These are for two purposes. One is for the thermometer and the other for the flash point determination. Insert a thermometer in the beaker, filled with the oil under test. Place the notched glass over this and the other piece of glass over that, taking care to cover the notch not in use. Now uncover this notch, note the temperature, and apply a lighted match to the opening. If nothing results, warm the oil slowly over a flame to a higher temperature and take another trial and reading. Continue the test until upon the application of the lighted match the oil vapor over the oil flashes. The thermometer reading at that point gives the flash point. The glass plates may now be removed and heating continued. The match is applied at similar intervals, until finally the oil burns, which will usually occur at about 50 degrees above the flash point.

An additional test is for precipitation at a known temperature. This is also made in a beaker. Two ounces is the usual amount. It is heated to the desired temperature, at which the oil may change color, but must not show a precipitation. Still another good oil test is the evaporation test. This is the result of slow heating, and the usual speci-

fication is that the oil shall not lose over 5 per cent. of its volume when heated to 150 degrees Fahr. for 12 hours.

Flash point, burning point and precipitation vary with the service for which the oil is intended, thus air-cooled motors always require a much higher oil test than those for water-cooled machines. As this is some indication of the quality, it is higher priced and harder to obtain, both in purity and evenness, and as a matter of convenience. Three hundred degrees is about the lowest flash point that should be accepted. With this would go 350 to 400 burning point and about 500 precipitation lower limit. In fact, oils may be had for any desired flash point and burning point up to 450. Beyond that they are hard to obtain. It is frequently claimed that this, that or the other oil will test 800 degrees, meaning the burning point. In the face of this statement, a simple home test as outlined above will prove whether or not you are getting what you are paying out your money for.

TIRE INFLATION EXPLAINED.

Editor THE AUTOMOBILE:

[1,858.]—There have appeared in your paper several letters asking about the effect of the Maxim tire inflator on the rubber of tires. In your answer to these letters you have allowed it to be inferred that explosive mixture or gasoline vapor is taken from the engine cylinders. As manufacturers of the Maxim inflator, we would like to have this wrong idea corrected. In the Maxim inflator nothing but exploded gas can get into a tire. If a moment's thought is given the question, this will be clear to anyone.

The tire must be inflated when the car is standing still. The engine, therefore, must be running idle. Now, an idle engine cannot be given its full throttle opening or it will race. If the throttle is not opened full, the compression cannot be normal. It must be very much below normal. This being the case, it cannot get out, as it cannot lift the inflator check valve. Hence, unexploded charge containing gasoline vapor cannot possibly get into the tire.

As only high pressure gas can lift the check valve, it becomes necessary to ignite the charge in the cylinder to get this pressure. But even the ignited charge of an idle engine is not high enough to get into a tire against the resistance of the tire valve and the pressure in a tire. It is, therefore, necessary to get at least some load on the engine. This is easily done by cutting out the ignition on three cylinders, leaving only the one fitted with the inflator to ignite. This gives good explosions in this cylinder, and a high enough pressure to inflate a tire. There can be no gasoline vapor in this gas. The only deleterious matter which can possibly get into the tire is oil, which may be carried over from an engine having excess cylinder lubrication. This is trapped, however, along with the moisture which is one of the products of combustion.

In inner tubes which have been inflated for over a year by this inflator, never having had anything else used on them, the rubber is distinctly better than is usually the case. All this has been proven by the Hartford Rubber Works Company, makers of Hartford tires, and many users of the inflator, after months of service.

F. A. LAW MACHINE COMPANY.
Hartford, Conn.

The point which the manufacturers have endeavored to bring out is that unless the mixture is correctly proportioned, that is, exactly right, the explosion pressure will not be the maximum and therefore will not be able to lift the check valve. In case the mixture is just right, it will be completely burned and thence no gasoline, vapor or otherwise, will enter the tire.

The effect of excess oxygen, hydrocarbons and oil will still be present.

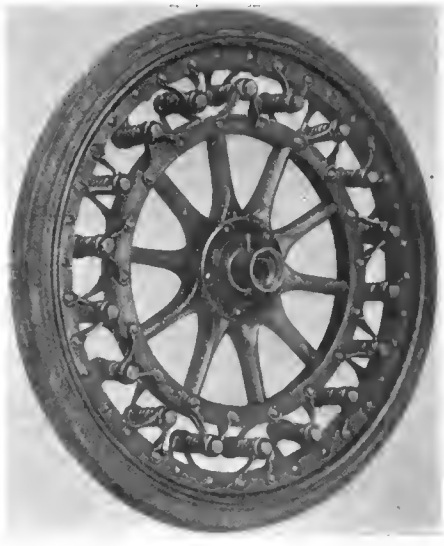
AN AMERICAN SPRING WHEEL.

Editor THE AUTOMOBILE:

[1,859.]—Being ourselves engaged in the manufacture of a spring wheel, we were very much interested in the article entitled "French Spring Wheel Appears Meritorious," in "The Automobile" of April 15.

Your account shows very clearly the manner in which this wheel works, but there are to our mind two disadvantages to this or any spring wheel dependent for its riding qualities on radial springs. The first and most important is that in a radial spring wheel, even where the springs are put in without tension, by far the greater share of the load falls on the springs immediately above and below the hub. The springs on the sides are almost useless, and unless they are fastened by a perfect ball and socket joint, so that the springs pull straight and do not bend, what little load they carry is carried at a tremendous disadvantage.

We notice in the article that two of the springs were broken. Wherever a spring is pulling out of line with its axis the likelihood of fracture is much increased. Moreover, as each spring in the radial spring wheel must in turn carry more than its share of the load, it must be made too heavy to give the proper riding qualities. In a wheel with the springs parallel with the hub, where each at all times bears only its porportional share of the load, the springs can be made light enough to give the desired riding qualities.



The Seaton Spring Wheel.

The second objection, we observe, has been recognized by the inventor, namely, the tendency to wabble or dish. He has incorporated a set of four solid braces. This, however, seems to us but a make-shift, as it is practically the same thing as depending for radial strength on four spokes in the solid wheel. With this construction, running up on curbs at an angle or turning out of car tracks would be very likely to prove disastrous.

THE AMERICAN SPRING WHEEL CO.
Cleveland.

The Seaton spring wheel is herewith shown. As the illustration reveals, the springs are coil springs, but are so used as never to be subjected to alternate tension and compression in a radial direction, as is the case with the French wheel previously mentioned.

DEFENDS WATER COOLING.

Editor THE AUTOMOBILE:

[1,860.]—In the issue of April 22, of "The Automobile," appeared a letter from the Franklin Company relative to air versus water cooling, in which some statements were made to which I wish to take exception. I have, personally, made a number of gasoline engine tests. In the most thorough and satisfactory of these, the results were such as to give a heat balance in which the percentage of heat converted into work was 20.76 per cent. for partial load, and 22.77 per cent. for full load. These results are not exceptional, as may be shown by the following similar figures taken from a well-known authority on gas engines:

Per Cent.	Test by	Place.
20.6	Unwin	London
20.6	Fernald	New York City
20.7	Robertson	Lafayette
21.0	Robinson	England
22.8	Kennedy-Tower	London
27.7	Spangler	Philadelphia
30.0	.....	Seraing, Belgium

The average of these with my own full load result amounts to 23.27. As resulting from no less than eight widely different, wholly independent, and careful investigators, this may fairly be taken as representing a more accurate figure than the 10-year-old one taken from Clerk.

Taking this as correct, then, the whole force of Mr. Holmes' statement, "We are safe in assuming that the water-cooled motor which we are testing would do no better," and the subsequent conclusion as to air superiority, vanishes into thin air. In fact, the whole letter, being based upon this, loses its force.

Instead of a gain in fuel economy as therein pointed out, the tables are turned and there is a fuel loss. It is hard to discover how the gasoline consumption was figured, but on the same basis the apparent gain of 14.1 per cent. drops to a loss of 21.3 per cent.

Strictly aside from the other points, which I do not wish to speak of as being likely to provoke a prolonged discussion, the above, based upon careful and reliable experiments, should be given equal weight with the previously published statements.

CHARLES A. FULLER.
Brooklyn, N. Y.

The above letter is published complete as sent in, and as the points brought out therein are self-evident, no comment will be made.

NOT MODEL T FORD.

Editor THE AUTOMOBILE:

[1,861.]—In my letter (1688) in which I asked you in regard to getting new piston rings for my model F Ford two-cylinder car, my letter was made to read model T, which is the new model and a four-cylinder car. Mine is, I think, the 1905 type; however, I have had it fixed up and it is running nicely. As it misrepresented the Ford car and was an injustice to the makers, I think it right that I should ask you to please make the correction. This should have been done before now, but I was away from town at the time and for some time after.

Pecos, Texas. J. B. NEILL.

We have printed the letter in full above, but fail to see where there was any reflection upon the makers. Piston rings wear out on four-cylinders as well as upon twos, and when so worn require replacement, regardless of make or type.

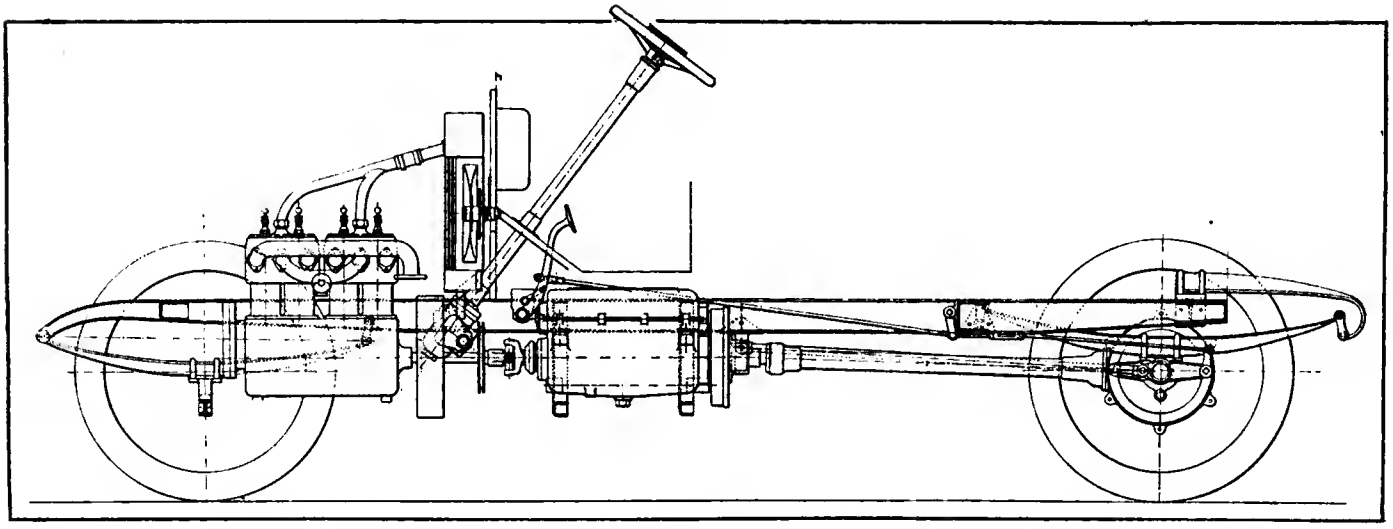
PUMP LUBRICATION.

Editor THE AUTOMOBILE:

[1,862.]—Will you please advise me what sort of lubricant to use on the water pump. Mine is of the centrifugal type.

Hoboken, N. J. A. K. LEE.

Grease is the proper lubrication for a pump, and it should be stiff enough so that the water will not wash it away. Be careful not to use too much, as highly heated water tends to carry it into the radiator and deposit it there, where it is liable to clog the circulation, or at least, reduce the efficiency of the radiator. See the article on "Automobile Cooling Systems Analyzed," March 25 issue of THE AUTOMOBILE, page 503, relative to the lubrication of pumps. It is there pointed out how a person may change the shape of the gears in a gear pump as to make it self contained as to lubrication. A somewhat similar method of procedure might be worked out for other types of pumps.



Ampere Looks Like Any Other French Car in General Appearance, Except for the Hand Levers.

ELECTRO-MAGNETS REPLACE MASTER CLUTCH ON FRENCH CAR

PARIS, April 20.—In the interests of simplicity, there have been many devices brought out, some of which did not survive the test of time and popular service. A newcomer here bears all the earmarks of being very much simplified, and, in addition, has been subjected to over two years of severe tests. Having survived this unscathed, it seems safe to any that the many unusual features incorporated in the Ampere Light Car are commendable.

The elimination of the clutch has long been a dream of automobile inventors. So, too, with the differential there have been attempts without number to simplify or dispense with that source of trouble and expense. Speed changing, the bugbear of the novice, is a continuous and never failing source of discussion. Then, when the new car is said to have no clutch, no differential, no speed change lever, and yet works satisfactorily, it is seen that the announcement is epochal, and the details of absorbing interest.

The fundamental principles of all of the sources of simple operation may be applied to any make of car, but the house of Ampere has, thus far, contented itself with a single light-weight model of 10-16 horsepower.

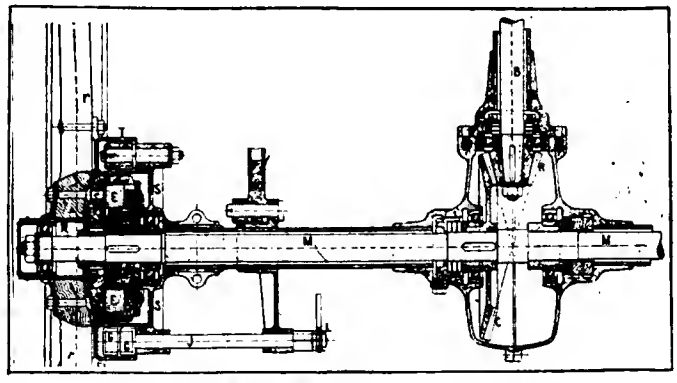
Engine Not Radically Different.—The construction of the motor is not unusual. The cylinders are cast in pairs, with ample water jackets, extending rather low down on the piston stroke. The latter is long, being 100 mm. (3.94 inch) for a bore of 80 mm. (3.15 inch). The valves are located on the left side of the motor and are interchangeable. The exhaust pipe is carried across the cylinders and down at the rear.

A very simple inlet pipe is, likewise, very short and leads to the carbureter, which is of special construction. The ordinary vaporizer is of the constant level type, with a float which maintains the fuel at a level, 1 mm. below the top of the spraying nozzle, this height having been proved right in practice. In the carbureter used on the Ampere, the level which gives the best results is 10 mm. below the nozzle tip. The lower level calls for a much stronger suction, and this is obtained by forcing the incoming air through the air passage at a correspondingly high pressure. At the same time this passage is so shaped that the air current is given a rapidly whirling motion. The latter, being a necessity in this device, is further augmented by the use, at the air entrance, of a series of fan-shaped blades which deflect it. In this manner a sort of whirlpool of air is formed, causing a central depression around the spray nozzle and is strong enough to suck the gasoline up for more than the 10 mm. necessary. The air pressure being varied according to the speed of the engine, the amount of gasoline drawn into the carbureter, which is entirely dependent upon this pressure, is exactly proportioned to the speed. Therefore, no fuel is wasted and condensation is prevented. Additional air enters the mixing chamber by an opening directly opposite to the first and so located that the two air columns meet one another.

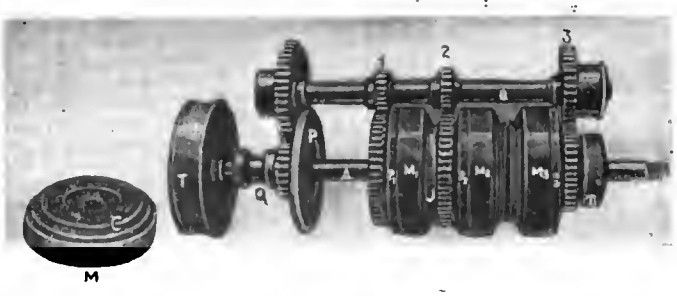
To return to the engine details, the crank case, of aluminum, is hung directly upon the main frame, which narrows at the dashboard for this purpose. The cylinders are cooled with water, circulated by a gear-driven centrifugal pump. The radiator, following the practice of Renault and C. G. V., is placed at the rear of the engine, on the front of the dash. It is of the vertical tube type, with a fan inside of it, driven by means of a belt from a pulley on the crankshaft extension.

No Sign of a Master Clutch.—The first sign of the difference between this car and any other lies in the flywheel and the gearbox directly back of it. The flywheel is for balancing purposes only, and as a result is of exceedingly plain appearance. Between this and the transmission is placed a single universal joint to care for the possible difference in level of the engine and transmission, the former being on the main frame, and the latter on a dropped subframe of channel section.

The transmission is of the individual clutch type, the clutches consisting of electro-magnets. As the small cut, displaying the parts, shows, the jackshaft is above the mainshaft. Upon the latter the gears are placed, which are clutched up to the shaft to obtain the different speeds. These are three in number, with direct drive on the high. To engage any gear a current is impressed on the windings of the magnet, which is keyed to the shaft. This attracts the plate carrying the gear, and, intimate relations having been established be-



The One-Piece Rear Axle Looms Up Large.



Transmission Parts, Showing Clutches in Place.

tween the two, just as would be the case with jaw or other clutches, the desired speed is obtained. There are four of these electro-magnets and four of the plates, that for the high speed being made integral with the gear itself.

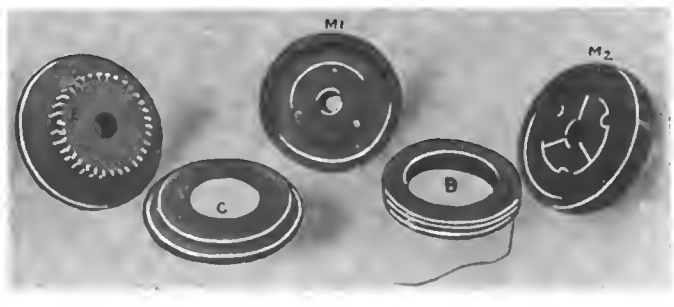
Magnetic Clutch Parts Look Very Elemental.—The other small cut shows the plates and other parts, comprising the whole of two clutches. One of these is separated and the other assembled. In the one which is taken apart, P is the plate, carrying the gear E. M_1 is a full view of the magnetic plate and shows the keyways, used in fastening it to the shaft. At B is the magnet complete, with a wire leading to the rings. On the right is the magnet set into place in M_1. These represent at the same time the gears themselves and their method of operation, and, with the case and bearings, complete the transmission.

Directly back of the gearbox is a brake drum and internal expanding brake. Operating here, ahead of the bevel gear reduction, the advantage in braking is increased in that ratio.

Cardan Shaft Drive Is Regular.—Seekers after variety will find none in the shaft drive, which is a good example of designing along standard lines. The driving shaft is enclosed in a stout tube and carries a universal joint at the front end only. The tube is free at the transmission end. The torsion rod is pivoted on the center line of the joint, so that its action is correct.

An inspection of the line drawing of the rear axle construction displays another excellent piece of designing. The differential will at once be missed and the resulting simplification noticed. The rear construction then simmers down to the gears themselves, their shafts and the requisite thrust and radial bearings. All of these are of the ball type, and provision is made to take thrust in both directions, an unusual feature.

One-Piece Rear Axle of Great Strength.—One outcome of the elimination of the balance gear is that it allows of the rear axle being made in a single piece, so proportioned as to have the greatest section at the point of maximum bending moment, the center. This gives great strength to the whole rear construction. On the outer ends of the rear axle are keyed a pair of magnetic clutches, one at each end. Except for the diameter, which is slightly greater, these are the same as the clutches used to operate the transmission gears. The mode of operation is the same, also. When current is turned into the magnet E, contained within a recess in plate D, the corresponding plate P, incorporated in the rear wheel, is attracted, and as long as the current passes and energizes the magnet, is driven by the rotating axle. As soon as the current is cut off the wheel is freed, due to road resistance and is no longer driven from the motor.



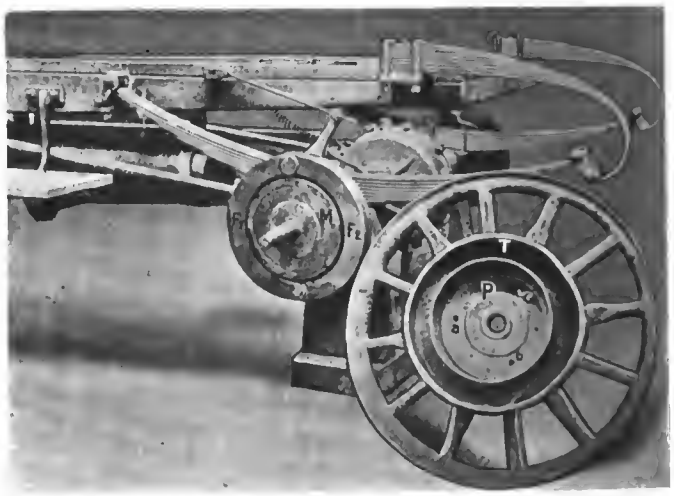
How the Magnetic Clutches Look When Dissembled.

Source of Differential Action.—This is the action which displaces the differential. The steering gear turns free up to a certain angle, at which it automatically cuts off the current to the inner wheel. The inner wheel, thus being disengaged and running free, while the outer wheel continues to drive the car, a perfect differential action is obtained. This is all done automatically by the movement of the steering wheel, and no manual work on the part of the driver is necessary.

The brake drums, wheels and other parts are standard, as is seen in the photograph, in which M is the magnetic clutch and F_1 F_2 the two halves of the hub brakes.

The control really displays all of the simplifications, at which the innovations are aimed. All told, it includes the steering post, on which are, besides the wheel itself, the spark and throttle levers, above both and in the most convenient place, a finger lever, which operates all speeds by a limited movement of perhaps 3-8 inch per speed. There are no hand levers and but two foot pedals. The right of these operates the brakes in the rear hubs. The other, answering to the ordinary clutch pedal, upon a slight forward movement, cuts off the current to all clutches, in which it follows the action of any other clutch. A further movement results in the application of the shaft brake. A toe pedal may be used for acceleration and is placed at the right.

Source of Electric Current Is Interesting.—The two sources of current, on the other hand, are of live interest, as on an



View of Rear Construction, with Wheel Removed.

electrically controlled car, like this one, the current furnished is the "whole thing." There are two magnetos, the ordinary one for ignition; the Nilmelior, driven from the crankshaft and located alongside the engine, opposite to the valves. For furnishing current to the magnets, another magneto is furnished. This is located upon an extension of the lower half of the gearbox, which extends from the side of the box to the main frame on the right side, forming a wide shelf.

This magneto is enclosed in a water-tight case and is belt-driven from the cardan shaft. It has been specially constructed, with special windings, to produce a current of perfect constancy, but limited amperage. At very high speeds the voltage increases slightly. This specially wound machine, it is claimed, has the advantage over accumulators for this particular work, of less weight, smaller loss of voltage, decreased danger of short circuits, and increased reliability. If desired, the cars may be had with accumulators, however.

The use of electro-magnets for speed changing is not new, having been tried by Panhard in 1898. This effort failed for the lack of a suitable source of current, but the present device, the result of much scientific research and exhaustive practical experiments, is believed to have overcome all former defects.

The disadvantages, which only years of use can bring out fully, are electrical complications, and the introduction of the magnetic clutch, not generally considered reliable.

Friction-Driven Cartercar, From Pontiac, Mich.

The Friction Drive and Enclosed Chain Make a Very Simple-Looking Outfit.

PONTIAC, MICH., April 26.—Which is preferable, three or four speeds? This question is one that is agitating numbers of manufacturers and users. It does not concern the makers of the friction-driven Cartercar, the Cartercar Company, of this city, for the user of this car may have either one or a combination of both, if desired. That is, the transmission to which this company has pinned its faith has an unlimited number of speed changes, one for every occasion. At the beginning, six years ago, the concern started with the idea of a friction drive. That it has been successful is borne out by the necessity for increased factory space. The present plant at Pontiac occupies five acres of floor space, totaling 218,000 square feet.

The production will be limited to two models, both embodying all of the newer improvements and all of the distinctive Cartercar features. These will be known as Models K and H. The former is continued from last season, while the latter is an addition to the line. Model K is equipped with a five-passenger touring body, and the motive power is the same two-cylinder opposed engine as has been used. It has a 5 1-2-inch bore and a shorter stroke of 4 1-8 inch. At a normal speed of 1,000 revolutions, the power developed is in excess of 22 horsepower.

Thermo-Siphon Cooling Featured.—The natural system of water circulation is used, without a pump or fan. With this system the water circulates more rapidly as it becomes hotter, and in the case of hill climbing or otherwise when the motor is working hard and running slow, more water is moved around.

The friction transmission is of very simple construction, with very few parts. It is, therefore, easy to care for and not expensive to maintain. Upon the prolongation of the crankshaft is mounted the aluminum disc, while against this a movable friction wheel with fiber facing presses. The latter is mounted upon a jackshaft and by sliding it along the various speeds are obtained. From this shaft, the final drive is by sprocket and chain to the rear axle. The chain is enclosed in a case of aluminum, which is said to be dust and oil-tight. Within this the chain runs in a bath of oil, which lubricates it thoroughly.

A series of experiments conducted by them with two cars running under parallel conditions for a distance of 6,000 miles resulted in a stretch of but 1-16 inch for the enclosed chain and in the shorter distance of 3,000 miles of 2 1-4 inch for the other chain, which was open and exposed.

One Speed Lever to Operate.—All of the speed changes are made by means of a single lever, located at the right of the operator in the usual position. This not only suffices for the forward speeds, but the reverse as well. In conjunction with this, the left-foot pedal moves the friction wheel into and out of engagement, like the clutch on an ordinary car.

One advantage which the makers of the car claim is that the transmission is practically fool-proof. In that it will stand endless abuse and hard driven with a minimum of repair expense, this is nearly true. The only part to wear is the fiber rim on the sliding wheel. This, it has been found, is good for 4,000 miles before replacement, which distance can be increased by careful driving. Replacement means little more than time necessary to do the work, as the fiber facing costs very little.

The wheelbase of Model K is 103 inches. The frame, which has a rise just above the rear axle for clearance, is of channel-section pressed steel, the dimensions being liberal. A dropped cross-member in front stiffens the construction there and acts as a cradle for the radiator. The other two cross stiffeners are located at the extreme rear and in the center, the latter carrying the transmission. The springs are of the now-generally accepted flat type. Both front and rears are semi-elliptic, and shackled at the rear end. The front axle is of the tubular form with large yokes aand extra large steering knuckles. The cross connection is placed at the front of the axle.

Popular-Priced Model, Too.—In addition to the larger car just described, another of the roadster class will be brought out. This is Model H and will have a four-cylinder vertical motor of 4-inch bore and equal stroke. This motor is also rated at 22 horsepower. The cylinders are cast in pairs with the valves on one side. The car has a 100-inch wheelbase, 32 by 3-inch tires and a three-passenger runabout body. This may, however, be changed from a single rumble to a double rear seat or a baby tonneau, as desired.

The Control Is Reduced to Foot Pedals and a Single Lever.

GASOLINE ENGINE CASTINGS A PROBLEM

VERY few of the owners or operators of automobiles, wrapped up as they are in their own operating troubles, stop to think of the troubles which the manufacturer has had previous to the final product. Chief among these sources of worry and friction is the matter of suitable castings, one particular branch,

Aluminum Cylinder Pattern and Tools Used in Making.

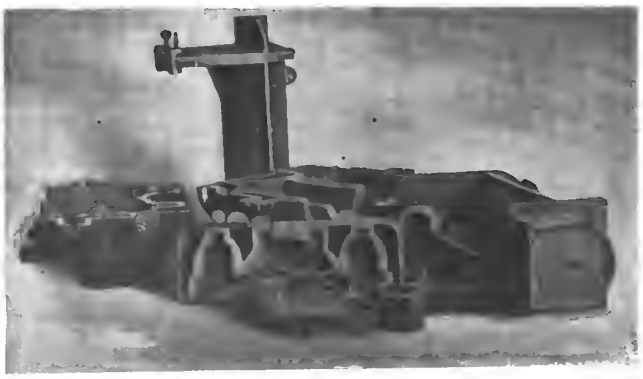
cylinders, causing as much trouble as all of the others put together, if not more.

Granting the necessity for suitable castings, it becomes necessary to produce them, and all large users are alive to the difficulties incident thereto. For instance, there is the matter of the material, usually gray cast iron; then the process has much to do with the finished product and its composition. In processes, there are two in general use: first, the ordinary cupola method, and, second, the air furnace. The former is an approximate way, as the exact composition cannot be assured, nor can the physical properties be controlled within the close range necessary for regular and even work.

In the air furnace, on the other hand, the metal does not come in contact with the fuel nor with the air, as there is no forced draft. As both of these items must exert an influence on the product, it follows that their absence makes for a superior iron.

Another item which looms up large on the trouble horizon is the matter of proper patterns and coreboxes. The first, it might be explained, makes the depression in the sand corresponding to the exterior of the desired casting. The molten iron when poured in would fill this up solid if it were not for the pieces placed therein, and these are known as cores.

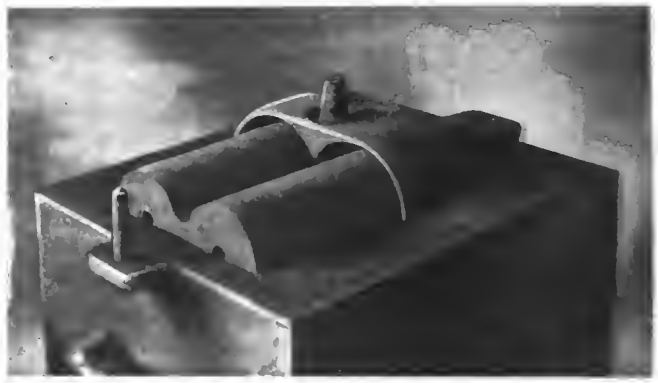
In the making of both patterns and core boxes, the greatest care must be exercised to have them fit together accurately, yet so as to go together and part with ease. This makes it easy for the moulder to handle them and results in better castings. Ordinarily patterns are made of wood, but in automobile work they are so expensive and used so much that it pays better to make them of metal. The metal employed varies just as the work to be done does. Thus, the cylinder pattern, which the moulder handles a great deal, lifting it from place to place, is made of aluminum to make it light. The core boxes, on the other hand, generally go to the core room and remain there. They are not handled or moved around much, so are made of a cheaper but heavier metal, cast iron.



Core Boxes Are Made of Cast Iron—A Typical Set.

Aside from the proper tools to work with, as exemplified by patterns and core boxes, the greatest care must be exercised in the work, and only careful workmen should be employed. The mold should be clean cut, dry, and evenly rammed. The sand should be well tempered, there should be plenty of vent area, and a lot of good judgment should be used in gating the finished mold. The cope and drag, the two parts of the molding flask, should match accurately, with cores set and vented with care. Much depends upon these conditions in securing an accurate, solid, and uniform casting. The matters of the tempering of the sand, venting, placing of the cores, gates and accurate matching of the flask parts are "up to" the molder. If cheap help is employed, and these important parts of the work slighted, the results will be such as to show the cause plainly. Tempering the sand, which means no more than mixing the proper quantity of old and new, and keeping the whole properly wetted, is directly "up to" him, and if lazy or underpaid, he will shirk it. If this is slighted the castings will show it.

The form and material of the flask also enter. Old wooden flasks cannot hold their shape and, consequently, the sand, as well as a more rigid flask, say, of iron. In the course of time



Half of Cylinder Mold, Showing Cores in Place.

nails and screws, set into the wooden sides, loosen up and allow lots of play or wobble. In matching up the cope and the drag, which must be as near exact as the foundryman ever works, this factor enters, as with the wooden form, the male and female points do not meet exactly on account of the wobble.

With iron, on the other hand, these cannot loosen, and the fit, if there is any, is exact. This sounds like a simple argument, but anyone who has ever seen the castings resulting from the former case will at once see the force of it. Half of the casting is in one plane and the other half is in another, due to the twisting which the loose pins allowed.

The matter of large prints for the main cores is one that is worthy of mention. With a small core print the long core of large diameter is able to be moved by the inflowing metal. If the mold is so gated that the iron flows to the two main cores of a casting with cylinders in pairs, from opposite directions, this will result in making the axes of the core spaces approach one another at the top. Then in machining the casting, the roughing cut will run out near the top of both cylinders, and after much work has been expended upon it the discovery is made that the casting is useless or a "waster."

The illustrations on this page which bring out clearly the points mentioned, were supplied by the Ferro Machine & Foundry Company, Cleveland.

How One Tours in New Zealand

By Walter Grace

Alone with Nature in the Northern Island.

EVEN in far-off New Zealand, a country whose interior is little known, and is as primeval as any part of the world in these days of exploration, where roads are such in name rather than in fact, leading between towns with unpronounceable names and whose inhabitants use a language equally beyond the understanding of most white travelers, automobiling is possible, but fraught with difficulties.

Having heard a great deal about the beauty of the wildness of the northern island, the engineering feats in railroad construction visible from the so-called roads, and of the general interest in the country through which the automobilist must pass, we decided to risk a trip from Wellington to Auckland, a distance of about 500 miles, paralleling the railroad on what is known as the Main Trunk route. The country scenery became fascinating as soon as it was entered and to Marton, 100 miles, we ran through old and well-settled country over fairly good roads. At Marton we entered the first stretch of our long run of 300 miles to the North through the practically unknown King Country. The conditions of the rough and bumpy roads, the logs and stumps all around and other unmistakable signs made it evident that we were entering country that only a few years ago was virgin bush.

Above Hunterville, we got the first glimpse of the Makohine Viaduct, and soon the huge structure burst into view. It is a grand sight. We descended into the Gorge and looked up at its great height—a Leviathan built to carry trains across the great rent in the earth, dive into the tunnel and disappear out of sight. While standing there we heard the shriek of an engine, a train rushed out of one solid wall of rock, with a roar crossed the slender structure and entered another one. We climbed out of the gorge and continued through Ohingaiti and Mangaweka, mushroom townships that sprang up in a night, the even purr of the engine spelling sweet music to our ears, till presently the road became rapidly worse. We passed through Utiku, where the sounds of many sawmills—New Zealand at work—greeted us. Each of these had contributed, with heavily loaded wagons, to cutting up the roads until it was nothing but a series of bumps. For a little while we were stopped by a team of working bullocks, whose ponderous movements reminded us of the middle ages. Holes, bumps and new stone for the next six miles, in to Taihape township, made the roads so bad that we took to the footpath, risking a summons rather than taking back to the road, even in the town.

Taihape seems a prosperous, business-like little town; whether it will continue so when the line is completed, with so much broken country around it, is another tale. There are several good hotels, nice-looking shops with plate-glass windows, and we had a fine lunch at the "Gretna." Here, also, we took on two cases of gasoline to see us through to the Auckland section and started off about two o'clock. The road wound round mostly a steady up-grade, with a creek or gully on one side and banks on the other, and our tires had to grind through loose rocks. We inspected them twice, but the good old Palmers on the back wheels were standing up to the ordeal like Britons. This stretch lasted for about 11 miles, and then the road lay through open, rolling country, where we made better going, though we could tell by the heavy pull of the engine that we were steadily rising as we neared Mt. Ruapehu. When we reached Taurangarere, we joined the railroad again, and at the highest point on the line (over 2,000 feet), ran through a dusty pumice soil onto the plains and along the right of the railway line, till we struck the Waiouru Accommodation House.

After the varied and broken scenery of Mangaweka and Taihape, with the Papa cliffs of the Rangitikei River rising sheer six or seven hundred feet from the river bed, with pretty bits of bush here and there, the tussock and pumice plains we had entered were deadly monotonous, so we decided to push straight on, and, after an easy run of about eight miles all down hill, reached the Wangaehu River at a fairly wide ford. I came back on to the low speed and sent her at it. It proved to be fairly deep water, surging well over the platform and round the bonnet and the current was pretty strong, but she took it like a duck. We were soon at Kerioi, and by our gas lamps the accommodation house was soon detected. We inquired the way and found that there were two creeks unbridged still to cross between us and Ohakune, and as one was two feet deep and the other not far off that depth, we decided to stop for the night.

In the morning we had reeled off a couple of miles when we came to the first creek. The ford was narrow and deep, with a treacherous looking soft shingle bank in the shallowest part, so we took the deeper. I did not disconnect the exhaust pipe at the engine, and when in the center the exhaust pipe got below the water and the engine was smothered. It was a case then of winding her out by hand. The second creek caused us no trouble for we found but 18 inches of water. From Ohakune we made a deviation to Raetihi, where we had lunch. From Raetihi to Pipiriki, 17 miles, the going was deadly rough and we had to proceed at a crawl. The road descends about 600 feet to the latter place, on the Wanganui River, and when about six miles

The writer of this story has spent practically all his life in New Zealand, knows the country blindfold, and will be pleased to supply any of our readers contemplating a trip through that country with any information or assistance in his power. Letters should be addressed to "Antipodes," care Editor this paper.

away the road became better. En route we passed along the famous "dress-circle," where the road winds around the Papa cliff in a semicircle. We were the first autoists ever in Pipiriki, and the Maori people were greatly interested in the car, surrounding it and looking under it to see the "horse." We returned to Raetihi that evening with our gas lights doing good work.

On the following morning we filled up and got under way for the main trunk line again, striking it seven miles above the point we had left two days previous. A couple of miles further brought us to another great engineering feat, the Makotote Viaduct, which was just as impressive in appearance as the other high bridge, and leaving it we again entered the bush country, soon finding ourselves at the top of the spiral where the railroad runs five miles to gain one in actual progress. We stopped long enough to take a beautiful panorama of the impressive scene, with the sinking sun dyeing the hills a deep red. The descent to Raurimu was easy, and about 15 miles further on we struck the head waters of the Wanganui River, running along it to Taumaranui, the terminus of the world-famous scenic route, "Wanganui to Auckland via Wanganui River, the Rhine of New Zealand." It is, in fact, all that is claimed for it.

Giving the Motor a Drink.

Here we learned that we could go 14 miles past Taumaranui to a section of three miles over the Poro-a-tareo tunnel, where there was only a horse track. So the car had to be hauled from Taumaranui to Te Kuiti. We spent Sunday morning overhauling the car and in the afternoon went out on the Wanganui River in a Maori canoe and enjoyed a swim. We reached Te Kuiti at 10:30 Monday morning, and in ten minutes we had shoved up a couple of planks and driven off the truck, cheered by the Maoris, who watched the unloading of the first automobile from the South. After inquiring the way, we started off to visit the Waitom caves, arriving there for lunch. In the New Raukuri cave, a huge cavern, we were led from gallery to gallery, examining the stalactites and stalagmites, taken through low-vaulted tunnels where the sound of rushing water became louder and louder until when the sound was well-nigh deafening, we realized that we were standing upon the brink of a precipice where the tunnel ended abruptly, and somewhere below us a torrent was dashing along in inky darkness. The thought of the danger and the wonder of it made us glad to turn around.

After a tramp back a mile and a half, armed with a lantern, we visited the Waitom caves, which proved a veritable fairyland, culminating in a wonderful grotto, with a pool of still but fresh water, and on looking up, we thought we had been transported into the heavens dotted with myriads of stars. Closer inspection revealed the presence of hundreds of glow worms upon the ceiling, giving forth in the darkness a beautiful, weird, soft and spectral light.

The next morning we got away for Hamilton, and after a run of about 60 miles, arrived there for lunch, finding preparations being made for a visit from the Premier, Sir Joseph Ward, and we were able to have an interview with him in the interests of automobilists, for he is one himself, in reference to the completion of a road over the Poro-a-tareo tunnel. When this bit of road is completed, or even as it is, I can recommend the Main Trunk route from Wellington to Auckland and vice versa as being one of the finest drives in the Dominion.

The ideal round trip leaving from Auckland would be to take the car on the boat to Coromandel, then via Thames, Paeroa, Waihi, Tauranga, Rotorua, Taupo, Napier and Wairarapa over the Rimutakas to Wellington, returning via Paikakariki, Palmerston, North Marton, Hunterville, Taihape and the Main Trunk to Hamilton, and on through Ngaruawhia to Auckland and vice versa for Wellington. By this route not a single inch of the ground would be duplicated, and some of the finest scenery in the colony would be traversed, including that little known but magnificent drive of 40 miles round the seacoast from Coromandel to the Thames, on the downward trip, and on the return, the lovely trip through the Main Trunk.

In looking back over the trip, it certainly can be recommended as one of the scenic ones of the world, especially interesting to those who have never visited New Zealand, or who have visited only the coast and do not realize that the beauties of the interior are without parallel. One feature of the trip that was a surprise to me was the number of tourists met en route, all traveling in coaches, boats or railroad trains, however, for we were the first to appear in an automobile. Our independence of time tables and of the dust and soot of the railroads, of the hot sun and dust of the coaches and the slow movement of the boats made us envied by the other less fortunate fellow-voyagers.

Maori Natives Manifested Great Interest in the Car.

While waiting for tea at Waiouru, the coaches from Pipiriki and Tokaanu arrived, one from the Wanganui river, 45 miles, and one from Lake Taupo. The passengers looked as if they had passed through a dust storm, and watched us start away in the cool of the evening for Ohakune. Another time we met a party, when quick action was necessary to prevent an accident. We had been running along at a good clip, when, on rounding a curve, we commenced the descent into the Sulphur Stream Gorge and came upon four coaches carrying His Majesty's mails, and all loaded with passengers doing the overland trip from Auckland to Wellington, via the Main Trunk. Down went our brakes, in went the reverse, and before the leaders had time to well realize what had startled them we had backed around the corner out of sight.

Mountains, volcanos, plains, plateaus, gorges, and, in fact, almost every kind of topography is seen in this trip. One of the most startling evidences of this was seen after leaving the Makotote Viaduct, and striking into the Waimarino plains, the road quickly changed from a good hard blue-stone to a sort of pumice twelve inches deep in dust. For ten miles, until we reached Raurimu, we re-entered the bush, the going was anything but pleasant. On the Maimarino plateau we caught a fine view of Ruapehu, Tongoriro and the active volcano, Ngarahoe.

LOWELL SECURES THE NATIONAL STOCK CAR ROAD RACES

LOWELL, MASS., will have the national stock car races, over the Merrimac Valley course, September 6 and 7, thus completing with the Wilkes-Barre hill climb and the Glidden tour the trio of national A. A. A. contests. With the light car event as the opener these speed tests will be the features of a week of automobile festivities planned by the Lowell Automobile Club and the people of that city. Both road races will be run under the classifications of the Manufacturers' Contest Association, and, of course, the sanction of the A. A. A., the latter organization having given the necessary permission to schedule the contests as of national interest and consequence.

At present the course over which the successful stock car competition was held last year is 10.6 miles long, but if sufficient entries are received for the coming one this can be increased to 15 miles. The plans for holding national races have all been made, and were well formulated before the A. A. A. was asked to make the meet of national importance. The entire system of roads to be utilized is such that it is in a natural amphitheater, with only two crossroads, both of which will be bridged. It is not more than half a mile from the main stretch of the route to the backstretch, and, although presenting difficulties for the drivers, it is not considered a dangerous course as circuitous courses go, and should prove very fast.

A $5,000 trophy has been guaranteed for the stock chassis race, and it will be for annual competition as the A. A. A. stock chassis trophy. A proportionately suitable prize will be given to the winner of the light car contest. The official permission to hold the meet was given by the executive committee of the A. A. A., subject to a satisfactory arrangement being made between the Lowell club and the Contest Board. The request of the Massachusetts body was presented by its president, J. O. Heinze, through the advisory committee of the M. C. A., and it is expected that the final agreements will be completed in a few days and official approval become a matter of fact.

Lowell's Mayor Calls Upon Citizens.

LOWELL, April 26.—The city officials and merchants of Lowell are becoming enthusiastic over automobile week in the Fall, and there is an assured prospect that sufficient money will be subscribed so that the series of automobile races and motor boat events can be carried out as proposed. Mayor George H. Brown is much interested in the plan for an automobile carnival and has issued an open letter to the citizens, asking their co-operation with the automobile club and the merchants in making the automobile week a success. His letter in part is as follows:

"The Lowell Automobile Club is planning to give this city the largest automobile carnival in the history of the country, and it is the duty of every citizen of every walk of life to realize the importance of this event, and to co-operate with the public-spirited men who are working to make it a complete success.

"While no official step has been taken on the part of the city to forward the arrangements of the carnival, I believe that the proposed week of events will be of two-fold importance to us, the advertisement which the city will receive throughout the country, and the financial benefits which will come to our business men and tradespeople; therefore I take this opportunity of calling upon the people of our city to give their moral and financial support to this project. Manufacturers are planning to have big exhibits here, and if this locality appeals to them it may be expected that they will ultimately open branch houses in Lowell.

"Of the sum of $10,000 which must be raised by the Lowell Automobile Club to insure the carnival of its financial success at the start, approximately $6,000 has been promised. I ask all our citizens who are interested to help swell the fund by their contributions. I trust that in every possible way our business men will co-operate with the club in this project."

INDIANAPOLIS SPEEDWAY RAPIDLY ASSUMING FORM

INDIANAPOLIS, April 26.—Progress in the construction work on the Indianapolis Motor Speedway, embodying several new features, is the subject of most general interest at present. The great race course is rapidly assuming its permanent shape, and much of the work on it has been completed.

It has been decided that asphaltum oil will be used in surfacing the track, to eliminate dust, and the five miles will necessitate the spreading of 235,000 gallons. The whole will be thoroughly worked in, rolled, levelled, and packed so that the gravel will not tear up. This is especially the case on the curves, which are 60 feet wide, and will be banked to a degree of 20 per cent. Unlimited speed may be attained upon the straightaways, and 112 miles an hour on the turns.

Should any car leave the course on a curve it will not turn turtle on the outside, dropping down to the level of the straightaway, for there will be a levelled and inclined space between the top of the curve and the boundry line for spectators, so that the driver will be able to straighten up before an accident occurs.

The immensity of the undertaking can be realized from the fact that there are five steam tractors, 300 mules, 150 scrapers, and four six-ton and three ten-ton rollers, now in use. It will require a carload of white paint to cover the four miles of outside and two and a quarter miles of inside fence. Through these there will be six entrances to the grounds, so arranged that any part of the course and the several stands for spectators may be easily reached.

There will be separate garages for each of the racing cars, and an 80-foot flag pole, the idea being that as long as a car is in a race its flag will remain hoisted, but if it drops out, the flag will be lowered. Different colors will be used. In addition to the main grand-stand there will be 20 individual stands to hold 40 persons each. A double-decked press stand has been built, and arrangements are being made for constructing a dark room for photographers. There will be eight special fouling and judging stands, so that the contestants will be under constant surveillance. Gasoline and oil houses, and water tanks, are being built.

Interest in the national championship balloon race of the Aero Club of America, which will start from the speedway grounds, June 5, has grown as the result of the efforts of the Aero Club of Indiana. Within two weeks amateur balloonists from three cities will arrive to complete the number of ascensions necessary to become registered pilots. Nine entries have been received, representing clubs of St. Louis, Chicago, Indianapolis, Buffalo, Boston, and New York. The gas mains from the city to the grounds, a distance of four miles, have been laid, and everything is in readiness for trial trips.

"BLUE BOOK" PATHFINDER AGAIN BUSY.

The "Official Automobile Blue Book" pathfinding car, which last year covered over 30,000 miles, started last Tuesday from New York for Ohio and Indiana to complete the work for Section 4 of the "Blue Book," which the publishers intend to be a complete guide to the Middle West States. The car will later on be joined by Robert Bruce, editor of the "Blue Book," who has been in Chicago for some time laying out routes.

The first German school of aviation has been formed under the auspices of the Bavarian Automobile Club.

BROOKLANDS HAS NOTABLE REOPENING

Winning Mercedes Passing the Fiat and Brasier Cars at the Rate of 100 Miles Per Hour.

LONDON, April 22.—Accompanied by magnificent weather and with a large and enthusiastic audience in attendance. the Spring opening at Brooklands was held on Easter Saturday and Monday, the program being pronounced one of the most successful ever held since the track was inaugurated. The entries were good and the programs run off without hitch on both days.

Saturday had five events and an "extra," the latter being a time trial on the recently constructed test hill by an 18-horsepower Straker-Squire, the best time averaging 18 1-4 miles an hour from a standing start.

The first event, the Easter Junior handicap, for cars up to 25 horsepower, was won by an 18-horsepower Straker-Squire driven by L. R. Squire, who took the lead at the start and held it throughout the three miles of the race, his average being 59 3-4 miles an hour.

The Weybridge cup for cars of 37 horsepower or under for the same distance was won by H. G. Nalder in a 35.7-horsepower Berliet, at an average speed of 62 miles an hour.

The chief event of the day was the Senior handicap for cars of 25 horsepower and over, the distance being 5 3-4 miles. The winner was A. W. Tate, on a 59.6-horsepower Mercedes, who started from scratch and gradually overhauled the field, winning by a small margin. The average speed was 87 miles an hour. This was the only event for private competitors during the day. In addition, there were two motorcycle events at five miles, the winners being H. H. Bowen and W. H. Bashall, both riding 3 1-2-horsepower Triumph machines.

Easter Monday's program was more attractive than that of Saturday. The attendance was somewhat larger by reason of the holiday, and in spite of a strong cold wind which arose. Showers in the morning had wet the track, and there were some exciting skids as a result, especially at the turns. Fortunately no one was injured, although a motorcyclist was thrown as a result of a seized motor.

The first event was for the Sizaire et Naudin Cup for cars of that make having a single cylinder motor of 120 mm. bore and 130 mm. stroke, the course being down the finishing straight, a distance of about a half mile. The result was a tie between W. H. Milburn and R. H. Hart, the former appearing to slow down so as to make a dead heat of the race. Later on the tie was run off and Hart won, Milburn being left at the starting line. The winner's speed was 36 1-2 miles an hour.

The Easter Senior handicap was the next event, it being for cars of 25 horsepower and over, the distance 5 3-4 miles. A. W. Tate, on a 59.6-horsepower Mercedes was the winner, although Baker White on a 60-horsepower Napier held the lead for over 5 miles, but was finally passed by both Tate, and J. W. Stocks on a 25.6-horsepower de Dion. Tate's time averaged 88 miles an hour. It was during this event that considerable skidding took place and several collisions were narrowly averted.

The Open Four-Inch race for 5 3-4 miles and for cars under the "Four-Inch" classification, was won by a de Dion, driven by W. V. Jolley, at an average speed of 68 1-2 miles an hour, the winner having about 50 yards to spare.

The final event was an obstacle race, in which the contestants had to keep within parallel lines about 25 yards apart and dodge a series of dummies, which were worked across the course, without leaving the lines. B. S. Millard on a 8.9-horsepower Sizaire won without touching a figure, his time being 34 seconds for the 100 yards of the course. The next competitor, A. R. V. Garnett on an 18.7-horsepower Straker-Squire took 32 2-5 sec.

STURMEY ON THE KNIGHT ENGINE TEST.

Henry Sturmey, one of the well-known British automobile authorities, in his comment printed in *Motor* gives expression to this opinion concerning the Knight engine:

I confess to a considerable feeling of satisfaction that the Daimler Company have at last carried out so searching an official test of the new Knight engine and with signal success, because I believe, while I was the first in this country to turn the Knight engine down by mental reckoning—which I did three years ago on seeing the drawings in an American paper—I was the first over here, I think, to accept it as a practical design (after seeing and trying it and hearing Mr. Knight's explanation on points I raised). I am saying nothing in this paragraph as to whether it is better, or more efficient, or more silent than the usual type of engine, but w am saying is that the test has shown that those who have re to accept the unofficial evidence presented to them and who stated, with more or less vehemence, that the sleeves could r lubricated; that there would be excessive wear, and that, f practical commercial purposes, it "could not work," have shown to be wrong.

Mr. Sturmey's opinion is that of a majority of British aut bile authorities who were also skeptical concerning the K engine, and held similar views regarding the wear and cation. The results of the bench and 2,000 miles test at B lands have demonstrated to all that the engine is a comm success and not an experiment.

Three Cars Taking the Expansive Bend in the Easter Handicap at Brooklands Track.

ROADS WILL BE BETTER FOR A. A. A. TOUR.

While the first three days of the A. A. A. tour, from Detroit to Madison, Wis., the travel is through an unpicturesque country, the scenery becomes fine after leaving Madison. In some respects, according in "Pathfinder" Lewis, it surpasses the scenery enjoyed on the Eastern tours. The pathfinding trip this year was begun two weeks earlier than usual, and the dirt roads that will be excellent in Summer are now long stretches of mire. Lewis says he has had more severe experiences than ever before, but that the route he is laying out will afford a more enjoyable contest and a better one in a sporting sense than in previous years. At times the roads have seemed impracticable, but he is sticking to it, and having a light car with 30 horsepower (an E-M-F.), he has not been stalled, but has progressed steadily, though slowly.

It has been the object of the A. A. A. Contest Board to make the tour this year of greater interest to the automobile users in general by making it of more value as an object lesson. This is to be done, not by making the contest more difficult, but by having the rules more exacting. The performances of the cars will be set forth with fuller detail, because of the improved rules, and motorists everywhere will get a better line on the possibilities of touring on schedule. There will be fractional points of penalization incurred for things not before penalized, and while the contest is certain to be close, it is expected in this way to evolve an individual winner for each trophy, without any car being discredited because of minor adjustments that are ordinarily experienced by everyone.

The interest being manifested by manufacturrs indicates that the entries this year will outnumber those of last year. Already a number of paid up entries are in hand, something which never before has been the case so far in advance of the tour. The entries this year close June 15, with $100 deducted from the fee of those who enter before May 15.

INDIANA REPRESENTATIVES IN A. A. A. TOUR.

INDIANAPOLIS, IND., April 5.—This State will have its usual quota in the annual tour for the Glidden Trophy during the coming summer, with perhaps additions to the number which have competed in the past. Webb Jay has announced his intention of driving a Premier, the first time that he has ever been at the wheel of a gasoline car in a big contest, and the first time he has been on the tour since 1906. George A. Weidely will be at the wheel of another Premier, and probably Ray MacNamara will handle the third.

It is understood that the Haynes will have its two representatives, with Frank Nutt in charge of one and Loring Wagoner, the other. At least one Marmon will be on hand under the guidance of Frank E. Wing, of Boston, who made perfect scores in both the 1906 and 1908 tours. Just what the Overland and National factories will do is not known, but it is thought that they will have cars in the run; the National may have a full team and the Overland both touring cars and runabouts. The Apperson has not been seen in tours for two years, but as it has been in numerous contests lately, especially hill climbs, there is a rumor that it will also be in the annual trek.

MARYLAND CLUB TO HAVE SEALED BONNET.

BALTIMORE, April 27.—A sealed bonnet endurance contest will be held May 15, under the auspices of the Automobile Club of Maryland, the route selected being from Baltimore to Frederick, then to Gettysburg, and back to this city. The cars will be placed in a garage upon return to Baltimore, and a committee of experts will make an examination. The slightest defect will entail a penalty. The cars will be divided into four classes: Touring cars up to 30-horsepower; touring cars above 30-horsepower; roadsters, and tourabouts under 30-horsepower, and roadsters and tourabouts above 30-horsepower. The running schedule calls for a finish within seven or eight hours.

REEVES VISITS INDIANAPOLIS SPEEDWAY.

That the completing of the new two-and-one-half-mile automobile track at Indianapolis marks an epoch in motoring, is the statement made by Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, who recently visited the new speedway. Th visit was made at the invitation of the officers of the new Motor Speedway, which includes Carl G. Fisher, A. C. Newby, F. H. Wheeler, and J. A. Allison. In the party were H. O. Smith (Premier Motor Mfg. Company), Benjamin Briscoe (Maxwell-Briscoe Motor Company), S. H. Mora (Mora Motor Car Company), R. E. Olds (Reo Motor Car Company) and W. H. Van der Voort (Moline Automobile Company), all members of the American Motor Car Manufacturers' Association. The visitors are enthusiastic supporters of the new plan which, they state, will result in the Middle West having the fastest course in the world, for the new track will permit of a speed of 100 miles an hour just as long as a car can stand it.

"One cannot appreciate the importance of the undertaking unless they have paid a visit to the new oval," said Mr. Reeves, Monday. "An army of more than 400 men living in camps on the grounds are literally 'making the dirt fly.' The contractors must finish their work by June 25, and the first race will be held July 15. The new course is beautifully laid out and will supply an ideal enclosure for aeronautical and motor sports. The piece of ground is more than one mile long and little over one-half mile wide, the entire undertaking involving an expense of a little more than $300,000."

THOMAS PATHFINDER REACHES IDAHO.

Automobiling touring in the Spring in Wyoming is particularly strenuous work, according to the reports sent East by the party which is mapping out the route for the New York to Seattle endurance contest. For sixteen days the Thomas car has been battling with snow, mud, and water in crossing the State of Wyoming, with short runs, at the start in Colorado, and now in Idaho where the roads are slightly better. On Wednesday of last week the car was dug out from a mudhole near Bitter Creek by a railroad section gang of fifteen men and then placed on a corduroy road specially built for it. Thursday was spent in making a snail-like progress, and Green River was reached Friday afternoon, after having spent five days in the 130 miles separating it from Rawlins.

Better progress was made Saturday, 88 miles being covered to Kemmerer, although a number of washouts had to be filled, and the crew felt that perhaps there was really hope of their reaching Seattle. Sunday evening no report was received of the whereabouts of the big car, but Monday evening it pulled into Montpelier, Idaho. Sunday night was spent with a camp of sheepherders out on the plains, with the temperature at zero. Pocatello was reached Tuesday. The roads did not improve as much as the crew had expected, on account of more snow, but with pilots, the party is getting slowly along.

The Manufacturers' Contest Association, by a mail vote, decided not to reopen the matter of the contest.

DETROIT GAINS MORE PLANTS.

DETROIT, April 26.—Another is to be added to the long string of automobile plants located here. A company is being organized to enter the light car, low priced field, and it is expected that the new model, which for the present will be an assembled car, will be placed on the market by June 15.

Recognizing the advantageous position Detroit occupies for makers of parts, the Buffalo Carbureter Company will locate in Detroit, the plant at Buffalo being dismantled and the machinery shipped here as rapidly as possible. A temporary location has been secured, pending the erection of a plant, and operations will be commenced with about one hundred hands. William F. White, president, and Robert A. Huessler, treasurer, will also make Detroit their home.

THE TRAIL OF THE ROAD-HOG.

Connecticut has one of the best systems of public roads in this country. Connecticut was the first State to abolish the arbitrary speed limit and adopt an automobile law based on equity and common sense. And although a very large part of the automobile travel on Connecticut's roads is by non-residents, these are nevertheless granted complete reciprocity. In every way Connecticut has endeavored to treat automobilists fairly, even liberally. What has been her reward may be best understood from the circular letter herewith, signed by the selectmen of the town of Berlin, which sees many passing autoists.

The selectmen of Berlin seem to be of a reasonable and peace-loving mind; there is no bombast, no hysterics, no suggestion of shot-guns or dynamite. Their letter is an appeal for justice, and it should be granted.

Unfortunately the comparatively few automobilists who are the cause of this complaint are not likely to be moved by any such consideration. It is Connecticut's misfortune, like New Jersey, to lie on the main route between two great cities. Much of the automobile travel on her roads is by through-trippers, whose only concern is to lose as little time as possible on the way. This class is the most dangerous, as it is largely made up of more or less reckless chauffeurs driving high-powered cars; and it is also the least amenable to reason. The local automobilist, who is acquainted with his neighbors for many miles around, must behave circumspectly in order to retain their friendship. The leisurely tourist—may his numbers increase!—wishes to see the country and make the most of a health-giving pastime. It is for the most part "through-trippers" and "record fiends" that make up the tribe of the "road-hog."

These considerations may soothe our self-respect, but they do not help Connecticut. The law-abiding class of automobilists must take this matter into their own hands; it may soon be a case of self-preservation. There is too much fellow feeling among automobilists; most of them seem to have the schoolboy spirit of protecting a comrade who has broken a rule. Every right-minded and conscientious driver should make it a point to report "road-hogs," and to see that his club takes vigorous action.

N. W. Baldwin,
E. W. Dyer.

Meetings
1st Day of Each Month.

Selectmen's Office
Town of Berlin

Berlin, Conn., April 12, 1909.

Dear Sir:—

The taxpayers of the Town of Berlin in the last few years have expended large amounts of money to improve our highways. We desire that the entire public shall have the benefit of these improved highways. Some automobilists, however, are using these highways at a speed which transgresses the law and jeopardizes the life and property of our citizens. We believe the majority of automobilists appreciate good roads and are desirous of observing the law relating to speed. We do not wish to take active measures against automobilists, but unless they use more discretion and cease to travel at the high rate of speed on the roads of the Town of Berlin we shall enforce the State law and do it rigidly.

We have no desire to antagonize automobilists, but rather desire to work with them, but unless they show a disposition to co-operate and cease to abuse their privileges, we shall rigidly enforce the law.

Yours very truly,

(Signed) W. H. GIBNEY, N. W. BALDWIN, E. G. ROCHE, Selectmen, Town of Berlin, Conn.

The man who ordinarily will not show consideration for others becomes even worse when placed at the wheel of a high-powered automobile. Secure himself, from harm, he cares little for those who may cross his path, and at times his conduct is such as to cause one to doubt if he is not bereft of his senses. Read on another page of the attitude of one across-the-State traveler who was remonstrated with by an observing and conscientious member of the Hartford club. Through the State, this trampler upon the rights of others was going, and little he cared for the law or those who were trying to preserve it. Small wonder is it that the citizens of Berlin and other Connecticut towns feel compelled to express themselves in terms that are unmistakable and justified. The law-abiding autoists must purge their own ranks.

Those who will not see simply because they won't, must be made to see. This reckoning has been delayed beyond the limits of the patience of the general public, which has yet to become thoroughly accustomed to the presence of the motor-driven vehicle.

HOW CONNECTICUT'S LAW IS ABUSED.

HARTFORD, CONN., April 26.—Many complaints have been made of late that out-of-State autoists touring through Connecticut have no regard for the law. A case in point is that of the reckless operation of a car bearing the New York State license number 60,967. An officer of the Automobile Club of Hartford, which organization is doing its utmost to preserve the present liberal law or bring about the enactment of a similar measure at least as good, noted the number of the car, which speeded down one of the main thoroughfares of the town and later encountered the driver at a local garage. He remonstrated with the driver, who laughed at him and stated that as he would soon be out of the State, the Connecticut law had no terrors for him. It is just such indiscreet action as this that is bound to put a crimp in the Connecticut law. It is needless to say that a close watch has been kept in general since the Legislature convened.

WISCONSIN MAY ELIMINATE SPEED LIMITS.

MILWAUKEE, WIS., April 26.—Officials of the Milwaukee Automobile Club and Wisconsin State A. A. are confident that the bill now before the Legislature, practically eliminating the speed limits for cars and making recklessness cause for arrest at any time and place, will be passed. The committee considering the measure has decided to report it favorably, after James T. Drought, counsel for the Milwaukee Automobile Club, made a vigorous argument in its favor and explained it clearly. The law makes the speed limit 25 miles an hour, but is so framed that a driver would be liable to arrest for violation if he ran recklessly in any part of the State. If a driver ran even as low as five miles an hour on a crowded street and that speed was dangerous, the driver would be liable to arrest. The bill enhances the police powers of the State while removing many harsh restrictions from owners of cars. It is an entirely new measure.

MOTOR FEDERATION NOW HAS 25 CLUBS.

WILKES-BARRE, PA., April 26.—The fourth annual meeting of the Pennsylvania Motor Federation was held at Wilkes-Barre, April 23, where the directors were the guests of the local club. Reports of the officers and chairmen of the legislative and good roads committee were decidedly encouraging, and general satisfaction was expressed over the passage through the Legislature of the Townsend motor vehicle law, which was the bill prepared by the Federation.

The board passed a strong resolution recommending that its clubs co-operate with the local authorities to secure a strict observance of the terms of the new law, and recommended that habitually reckless drivers who cannot be controlled be not only publicly expelled, should they be members of automobile clubs, but that the club officials aid in securing convictions which would entail a jail sentence or the revocation of license or registration.

The secretary's report showed an enrollment of 25 clubs, with a total membership of 2,600, an increase of 10 clubs and 800 members within the year.

The Cumberland Valley Automobile Club, the Beaver Valley Motor Club, the Juniata Valley Motor Club, the Chambersburg Motor Club, and the DuBois Automobile Club were elected to membership.

The good roads committee have plenty of work cut out for them in the preparation of a system of main State highways and the codification of the road and bridge laws of the State, to be used in the preparation of legislation to be presented in 1911.

Robert P. Hooper, of Philadephia, was re-elected president; Peter A. Meixell, of Wilkes-Barre, and John A. Wilson, of Franklin, vice-presidents, and Paul C. Wolff, of Pittsburg, was again asked to serve as secretary and treasurer.

Joseph H. Weeks was reappointed chairman of the good roads committee, S. Boyer Davis of the legislative committee, and L. P. Backey of the publicity committee. The appointment of a chairman of the touring committee was withheld for the present.

A. A. A. HAS TWENTY-NINE STATE BODIES.

NEW YORK, April 26.—There are now twenty-nine affiliated State organizations in the American Automobile Association, through the election of Utah and Iowa bodies at the meeting of the executive committee, held at national headquarters, April 21. Besides the Utah Automobile Club and the Iowa State Automobile Association, the Adams County Motor Club, of Natchez, Miss., and the Montgomery Automobile Association, of Montgomery, Ala., were elected as unfederated clubs. In Mississippi and Alabama, plans have been started for State bodies.

The place and the date of the second annual good roads and legislative convention will be announced shortly, according to Chairman George C. Diehl, who has this matter in charge.

Those who attended the meeting of the executive committee were: President Lewis R. Speare, Boston, who presided; W. C. Crosby, president, and H. A. Bonnell, secretary, Associated Automobile Clubs of New Jersey; Robert P. Hooper, president, and Paul C. Wolff, secretary, Pennsylvania Motor Federation; J. P. Coghlin, president, Worcester Automobile Club; G. H. Gillette, secretary, Connecticut State Automobile Association; L. J. Powers, Jr., Springfield Automobile Club; Alfred Reeves, general manager, A. M. C. M. A.; E. P. Chalfant, general manager, A. L. A. M.; Charles Thaddeus Terry, New York; F. H. Elliott, secretary, A. A. A.

CLEVELAND AFTER A. A. A. CONVENTION.

CLEVELAND, April 28.—The Cleveland Automobile Club, supported by the Cleveland Chamber of Commerce, is going after the next annual convention of the American Automobile Association, according to an announcement made by Secretary C. J. Forbes, Jr., of the local Automobile Club.

President W. F. Bonnel, of the Cleveland Automobile Club, and Harry L. Vail, president of the Ohio State Automobile Association, expect to leave for New York City this week, in an effort to bring the matter to head. They will urge the desirability of Cleveland as a meeting place for the A. A. A. The local club has the enthusiastic support of the Cleveland Chamber of Commerce, the leading organization of this city.

CUT-OUT NOT A SIGNAL DEVICE.

MILWAUKEE, April 26.—The municipal court at Racine, Wis., has decided that the "cut-out" is not a signal device in the meaning of the law, and Roy Easson, a tester for the Mitchell Motor Car Company, of Racine, was fined $10 and costs. An appeal has been made to the Supreme Court. George Peterson, chairman of the town of Mt. Pleasant, swore out warrants for the arrest of Easson and two others of the nine Mitchell testers, claiming that as they had no bell or horn they were guilty of violating the law requiring signal devices. Each machine, however, was supplied with a pedal cut-out, which constituted the defense.

In Milwaukee there are hundreds of machines whose only signal device is the cut-out, and the only threatened prosecution in this connection has been by a nervous man who thought the cut-out made unnecessarily loud noises. Many Ramblers are supplied with nothing in the way of signal devices except the pedal cut-out, and the testers of the Kenosha product have experienced no trouble.

NEW YORK'S PROPOSED LAW PROBABLY DEAD.

ALBANY, N. Y., April 28.—The Allds bill, to provide a motor vehicle law without a speed limit, to-day was amended in the Assembly so as to put in a speed limit and permit local regulations, in addition to a clause to shut out automobilists from States where New Yorkers are not allowed reciprocal courtesies. There was a rising vote of 71 to 48, and New York City members joined those from rural counties in voting for the amendments which kill the bill unless the Governor sends in an urgency message for passage as amended during the next two days.

SUGGESTED RULES TO GOVERN OBSERVERS IN CONTESTS

FEW of the endurance contests scheduled for the coming season are run without the use of the observer system, whereby each entrant nominates some one to ride on a competitor's car. Frequently it has been found in the past that the observers did not understand the conditions, and inasmuch as their principals were only indirectly affected by laxity, did not do the full duty expected of them. To overcome this, E. C. Johnson, of the Keystone Motor Car Company, of Philadelphia, formerly a chairman of the contest committee of the Quaker City Motor Club, and an official in many races and road contests, has compiled a set of rules in which special attention is paid to the observer question. The regulations were planned to be used in connection with endurance runs of the Q. C. M. C., and provide for the whole affair, only that section applying to the entrants' representatives on other cars being considered here.

In regard to observers, the rules say: "The committee will hold each entrant responsible for the action of the observer named by him"; and in the list of penalties, under the section on observers, the following are the regulations:

Each contestant shall nominate a responsible man to act as an observer. This man will be placed in one of the contesting cars, and it shall be his duty to keep accurate record of all replacements, adjustments, motor stops, etc., on a card furnished each day, this card to be turned over to the chairman of the contest committee at the termination of each day's run. Contestant nominating such observers will be held responsible for the proper performance of his duty, and will be penalized as follows, should he fail in said performance:

(a) 10 points for failure to record the actual time of passing each checking station, and at the night control.

(b) 10 points for failure to record all adjustments.

(c) 5 points for failure to record all replenishments.

(d) 20 points for failure to record all motor stops.

(e) 50 points for failure to deliver observer's card to a member of the contest committee within thirty minutes after checking in at the night control, or at the termination of the run.

(f) 100 points for failure to record any assistance received during the progress of the run.

(g) 1000 points for deserting the car before the completion of the run.

(h) The refusal of an observer to make an affidavit as to the correctness of his report, should such be desired by the contest committee, will be sufficient grounds for disqualifying the entrant nominating such observer.

Some of these penalties are very severe, but it must be remembered that if the observer fails in any of these particulars the car in which he rides may be heavily penalized by something over which its crew has no control, and that it is just to inflict the penalty upon the nominee of such an individual.

FIRST ENTRY FOR GERMANY'S BIG TOUR IS DISAPPOINTING

BERLIN, April 22.—First entries for the Prince Henry tour have closed, with the somewhat disappointing result of 111, against 145 of last year's first entry. It was believed that Austro-Hungary's active participation would have brought a great number of competitors together; at present, however, only eight have entered. The three credit points for the less experienced drivers have not kept any of Germany's big guns away, and Poege, Erle, Held, Opel, Lindpaintner, Stoess, Benz, Mathis and Bugath will all come up to the mark.

Germany is naturally very much to the front with 80 entries, 16 of which are Opels, while Mercedes and Benz are down with nine cars each, and the other firms in equal proportions.

Belgium and Italy have entered nine cars, Austria eight and France five, while England, Holland, Switzerland and the United States are completely lacking.

It is also unlikely that the severe regulations to keep freaks and specials out of the event will be of much avail, as some of the stroke measurements afford very remarkable reading. Horch has built an engine with a stroke of 170 millimeters to a bore of 85 mm. The Gaggenau cars are described as having a bore of 100 and stroke of 200 mm. One of the smallest Opel cars has a bore of 70 and a 125 mm. stroke. Poege's Mercedes is fitted with a 90 by 140 mm. motor. It will be interesting to see what the regulation touring cars will be able to do against these special designs. Among all the first 111 contestants there are only two six-cylinders, these being the Protos cars.

ACCESSORY ASSOCIATION NOW HAS NEW YORK QUARTERS

NEW YORK, April 26.—Representing 180 manufacturers of automobile parts and supplies, the Motor and Accessory Manufacturers now have headquarters in New York City, accessible to members who come to the metropolis, and comfortably located at 17 West Forty-second street. This organization is composed of makers who furnish automobile factories, dealers and garages with nearly all of their supplies, and is chiefly occupied in acting as a clearing house for information, introducing new concerns, and in deciding policies of national importance.

The manner of participating in the annual shows, and of not going into the local ones on account of the great number and consequent expense, is a matter considered by the accessory manufacturers through the association. Membership gives numerous advantages: prestige of being associated with prominent firms and men in the industry; protection against a wave of price cutting, although it does not attempt to control or even to fix prices, as this would be in defiance of the interstate commerce laws; and the advantages of a clearing house of experienced tradesmen. This last is an important feature of the work of the central office, for on its lists are the names of over 3,000 purchasers of automobile supplies, and all are garages, dealers or factories, none being individual buyers. The members of the association give information regarding their customers, but the name of the member filling out the blanks is not noted. Other members may at any time write to the office in this city asking for the credit of rating of prospective purchasers, and thereby know just how to treat matters of credit.

The organization is growing rapidly, an average of five new firms being elected at each quarterly meeting. The officers are:

President, H. E. Raymond, B. F. Goodrich Company; first vice-president, H. T. Dunn, Fisk Rubber Company; second vice-president, F. E. Castle, Atwood-Castle Company; third vice-president, C. E. Whitney, Whitney Manufacturing Company; treasurer, W. S. Gorton, Standard Welding Company; secretary, P. S. Steenstrup, Hyatt Roller Bearing Company. The directors are: H. S. White, National Tube Company; D. J. Post, Veeder Manufacturing Company; C. T. Byrne, Byrne, Kingston & Company; H. W. Chapin, Brown-Lipe Gear Company; E. S. Fretz, Light Manufacturing & Foundry Company; L. M. Wainwright, Diamond Chain & Manufacturing Company.

The New York office is in charge of H. M. Street, from whom information regarding membership can be obtained.

What the Clubs are Doing These Days

HARVARD TROPHY AT BAY STATE MEET.

BOSTON, April 26.—The complete list of events for the June 17 race meeting of the Bay State Automobile Association at Readville track has been announced by the contest committee, of which Chester I. Campbell is chairman. There will be eight events, the most important of which is that for the Harvard trophy, offered by students of Harvard College for a 25-mile event open to all cars. In addition to the trophy the winner will receive $500 in cash, while cash prizes of $200 and $100 are offered for second third. It is expected that a number of fast cars owned by students will compete in this event. Another trophy race is that for the Automobile Trade trophy. This is to be at 10 miles for cars over 36 horsepower, close coupled and baby tonneau bodies being excluded. The third trophy event is that for the Bailey trophy at five miles for stock cars to be driven by owners. The complete list of events is as follows:

1—Five miles, for Bailey trophy, open to stock cars to be driven by owners or their representatives not having any connection directly or indirectly with the automobile trade, no chauffeur or professional driver.

2—Twenty-five miles, for Harvard trophy, open to all cars. First prize, the trophy and $500 additional; second prize, $200; third, $100.

3—Five miles, open to touring cars up to and including 24 horsepower, close coupled and baby tonneau cars excluded. First prize, cup; second, gold Bay State Association medal; third, gold Bay State Association medal.

4—Five miles, open to touring cars up to and including 36 horsepower, close coupled and baby tonneau cars excluded. First prize, cup; second, silver plate; third, bronze plaque.

5—Ten miles, for Automobile Trade trophy, open to cars over 36 horsepower, close coupled and baby tonneau cars excluded. First prize, trophy; second, silver plate; third, bronze clock.

6—Three miles, open to stock car, roadsters or runabouts up to 30 horsepower. First prize, cup; second, silver plate; third, Bay State Association medal.

7—Five miles, open to stock cars, roadsters or runabouts, 31 horsepower and over. First prize, cup; second, gold Bay State Association medal; third, gold Bay State Association medal.

8—Special match race, to be announced later.

The contest committee is composed of Chester I. Campbell, secretary of the Dealers' Association, chairman; F. E. Wing, the Marmon agent; C. J. Bailey, the Bailey tire tread manufacturer; Walter G. Schmunk, of the White company, and James Fortescue, secretary of the Bay State Association. The track has been secured and will be put in first-class condition

In addition to the races the association is planning several other events, including a club run to Providence on Memorial Day, a hill climbing contest on the Fourth of July, and an endurance run to be held later in the season.

COLUMBUS AFTER A GREATER MEMBERSHIP.

COLUMBUS, O., April 26.—The Columbus Automobile Association will start an active campaign for membership May 1, which is the beginning of the fiscal year.

The Supreme Court of Ohio has granted leave to T. M. Drolesworth, of Summit county, to file a test suit against the State automobile law. The complainant was fined for violating the law. He contends that the law is unconstitutional because it prescribes unequal fees and gives the State a monopoly of the business of furnishing tags. Automobile owners do not believe that the suit will succeed in overthrowing the law.

LARGE ADDITION TO LONG ISLAND CLUB.

BROOKLYN, N. Y., April 28.—In the new house of the Long Island Automobile Club the regular monthly meeting this evening resulted in the election of one of the largest membership lists ever proposed in the history of the organization. Fifty-four additions were made, 49 of these being to resident membership, while the remaining five were non-residents. The opening of the club garage, with its accompanying club-room facilities, has been a great success.

MORE CLUBS FOR A. C. C. OF NEW JERSEY.

NEWARK, N. J., April 26.—Organization of more county clubs and the strengthening of those already formed is taking much of the time of the officials of the Associated Automobile Clubs of New Jersey. Last week Frederick H. Elliott, secretary of the American Automobile Association, and Horace A. Bonnell, secretary of the New Jersey Federation, went to Plainfield to reorganize the club established there and place it on a firmer footing. There are a large number of automobile owners in the vicinity of Plainfield, and the local club promises to form the nucleus of one of the strongest bodies in the State.

The Warren County Automobile Club, with eighty members, has applied to Secretary Bonnell for the conditions of membership in the Associated Clubs, and will probably join the State organization within a month. This will strengthen the State body, as there has been no representation in that part of New Jersey covered by the Warren County Club.

SYRACUSE CLUB WILL POST SIGNS.

SYRACUSE, N. Y., April 26.—Secretary Forman Wilkinson states that the Syracuse Automobile Club will carry on a vigorous sign placing crusade this Summer, a stock of 100 signs having been ordered, in co-operation with town boards or village officials throughout this section of the country. The signs will be at the call of the townships, and the club will welcome the assistance of autoists in ascertaining needed location for these direction guides. The agitation against joy riding is supported locally, for there has been some prevalent, and the club has resolved to use its influence to have this practice stopped and a stricter adherence to the speed laws observed.

Permanent club offices will be opened on May 1 in room 606, S. & A. K. building, where accurate information regarding routes will be kept for the use of tourists.

CENTURY AUTOMOBILE CLUB TO BE LIVE WIRE.

PHILADELPHIA, April 26.—The Century Automobile Club, the successor of the Century Wheelmen, is preparing to enter actively into the competitive game. As a first step toward this end a live committee on contests, tours and entertainments has been appointed, which will open the season with a smoker in the club's handsomely appointed theater on Saturday evening, May 8. On Sunday, May 16, two score cars will participate in the initial club run, destination to be announced later. Later in the season a one-day open endurance run to one of the North Jersey coast resorts will be put on, and a winter reliability contest is also talked of. It is the intention to have these events for amateurs primarily, for there are more private owners taking advantage of the new club, than of the trade. Improved rules have been outlined, embodying some new features.

ANNUAL ELECTIONS ARE NUMEROUS.

Schenectady, N. Y., April 26.—The following board of governors has been elected by the Schenectady Automobile Club, and they will act as chairmen of the following committees: Membership, George Close; laws and ordinances, W. D. Loucks; exhibits, tours and contests, W. J. Close; good roads, E. F. Peck; grievance, Walter Green; publicity, F. R. Champion; extension, T. H. Soren; signs, E. J. Vrooman.

Middleboro, Mass., April 26.—At the annual meeting of the Middleboro Automobile Club the following officers were elected: President, Levi O. Atwood; secretary-treasurer, Chester E. Weston; directors, L. O. Atwood, C. N. Atwood, C. W. Maxim and A. A. Thomas.

ENLARGED OUTLET FOR FRONTENAC CARS.

NEWBURGH, N. Y., April 26.—Activity is the keynote of the work now being carried on by the automobile department of the Abendroth & Root Manufacturing Company, of this city, the manufacturers of Frontenac touring cars and roadsters. The supposed lateness of the building and selling season has had no appreciable effect here, and it seems that there must be a shortage of high grade cars of from 40 to 45 horsepower which has resulted in a large outlet for the Frontenac. This automobile has an engine of 40-45 horsepower and in all particulars is of standard design and construction. The manufacturers have an established reputation of 40 years' standing as makers of machinery, and have allied this to the production of autos.

J. J. Evans, who was fromerly connected with the marketing of the American Mercedes, has just taken charge of the output of the local plant. Agency propositions are at present being considered, and early deliveries assured. In addition to the cars for pleasure purposes, there is also a Frontenac truck which has proven successful, and this will also be made in quantities.

AN ESPECIALLY CONVENIENT AMBULANCE.

INDIANAPOLIS, April 26.—The new ambulance for the Board of Health will be unusually convenient, several points of up-to-date construction having been utilized which have never been found in

Electric Ambulance Just Completed by Waverley Company.

an ambulance before. Chief among these are the electric heater, the convenient arrangement of the electric buttons, special drawers for surgical instruments and the appliances for the control of folding seats and stretchers. Worthy of mention also is the door arrangement. This differs from the ordinary in that two large side doors are used, these being 23 inches wide and opening into an interior open space of 18 inches by 3 feet 10 inches. The open space is located in front of the stretchers, convenient for the surgeon and attendants, while close at hand are the other conveniences.

The dimensions of the body are: Length inside, 8 feet 5 inches; width, 5 feet 10 inches; height, 5 feet 4 inches. The sill is 32 3-4 inches from the ground, and the step is 19 inches up. The wheelbase is 97 1-2 inches, and the tread standard. The chassis is of armored wood, with motor and battery attached to it and thus independent of the body. The motor is large and of exceptional overload capacity. It is operated from a 42-cell, 13-plate battery, constructed for speeds from three to fifteen miles, and an emergency speed of 20 miles per hour. Control is through a four-speed controller.

The interior is handsomely finished in polished hardwoods, with russet leather curtains and upholstery. In this vehicle the builders, the Waverly Company, of Indianapolis, have carefully studied the comfort of the patient as well as the serviceability of the car as a whole. The white color of the exterior gives it a typical ambulance appearance.

LATEST NEWS FROM TIRETOWN.

AKRON, O., April 26.—A combination of interests representing the leading companies in the United States manufacturing tire rims is to be effected in this city shortly, an important step having been taken April 23, when the United Rim Company was incorporated at Columbus with $10,000 capital stock. The object of the company is not to manufacture rims, but to take further steps toward their standardization.

The incorporators of the company are Edwin C. Shaw, general manager of the B. F. Goodrich Company; P. W. Litchfield, superintendent of the Goodyear Tire & Rubber Company; Arthur H. Marks, vice-president and general manager of the Diamond Rubber Company; H. E. Raymond, sales manager of the Goodrich Company, and Ernest Hopkins, representing the United States Rubber Company, of New York. This company will probably succeed what was formerly known as the "Rim Association," and through the new arrangement one rim will now hold a tire of any size. Companies making rims in the United States are the Diamond Rubber Company (Marsh rims), the Goodrich, Goodyear, the Midgeley Manufacturing Company and the Standard Welding Company, of Cleveland.

The Diamond Rubber Company is following extensive additions to its plant made last year by two large ones planned for this year. The company has begun on a new laboratory that will be 148 feet long by 50 feet wide and three stories high. It is said that it will be the best equipped India rubber laboratory in the United States. Another immense addition will be started soon for factory purposes. It will be 200 feet long, 100 feet wide, and five stories high.

The cross-country auto transit business is becoming a very active industry in this part of the State. This week the Akron Motor Transit Company was incorporated by Akron men with $10,000 capital stock for the purpose of operating auto cars between this city and the Summit lakes, south of Akron, three to five miles. The service will begin Memorial Day with a specially built 30-passenger, 60-horsepower autobus. The company is to take the place of an interurban car line that was incorporated, but which did not secure sufficient capital to be put in operation. Another auto bus line just starting is operating between two towns west of Akron, and will form the connecting link between two important systems of electric lines, both of which connect with Cleveland and eastern and western points. Still another auto line is to connect a number of county seats adjoining counties where electric lines were first proposed.

SPEEDWELL WILL TRIPLE SIZE OF FACTORY.

DAYTON, O., April 26.—Having increased its capital from $50,000 to $250,000, the Speedwell Motor Car Company has announced that it will triple the size of its present factory. Three acres of ground in Edgemont, adjacent to the plant, have been purchased, and on this will be erected a big modern concrete building of up-to-date construction.

Other improvements will follow, and the officials of the company announce that within a year more than 1,200 workmen will be employed. This increase is the result of the growing business in Speedwell automobiles, and additional factory accommodations became necessary. The officers of the Speedwell Company are: President, Pierce D. Schenck; vice-president, M. L. Sternberger; secretary and treasurer, R. A. Herbruck; general manager, J. G. Loomis.

ANOTHER MOTOR BUGGY FROM ILLINOIS.

ROCK ISLAND, ILL., April 26.—Automobiles of the buggy type in four different styles will be built in this city by the Geo. White Buggy Company, and will be marketed under the name of White. The motor will be a two-cylinder air-cooled one, geared with a ratio of 10 to 1, giving a maximum speed of 24 miles per hour. The wheels will be of medium size with large solid rubber tires. No foot pedals will be used in the control.

The Systematic Arrangement of the Pierce-Arrow Factory's Stock Room Is a Delight to the Visitor's Eye.

HOW SYSTEM RULES IN ONE FACTORY.

BUFFALO, April 26.—Among the first things considered by the factory manager when a new plant is being constructed is the amount of space to be given to rough and finished stock, and the location of the rooms. Poor stock room facilities and a lack of system in an automobile factory will nullify all plans for economy in plant operation and certainty of output. In the early days of the industry new concerns occupied factory buildings that had been constructed for the manufacture of something entirely different. Makeshifts were necessary in the arrangement of stock rooms, machinery departments, and assembling floor, and parts, in taking their course through the factory, often crossed their own paths as many as a dozen times. Loss of time, the taking up of floor space, loss of parts, and confusion were among the necessary disadvantages of this system.

With the growth of the industry came a new order. When building new factories solely for the manufacture of automobiles, economy in operation was given serious consideration. Manufacturers of not only automobiles, but other articles as well, have no hesitancy in expressing great admiration for the arrangements of floor space, and of manufacturing systems employed at the new plant of the Pierce-Arrow Motor Car Company. The only way in which a part crosses its own path between the time it enters this factory and is placed in position in the cars, is when more than one machine operation is necessary to finish it from the rough stock stage. In this case it is taken to the inspection department after each operation, and when it has been passed upon there is returned to machinery hall. In their sequence to the assembling floor from the railroad siding where the rough stock is unloaded, the departments are: Receiving room, rough stock department, machinery hall, inspection department, finished stock room, assembly floor. A straight line is scarcely deviated from, from the railroad siding to the assembly floor, the only changes from the direct route being the jogs necessary in going to various machines on the way to the inspectors. The machine shops and inspection rooms are so located that the direction is always a short, straight one, and when necessary to go to upper floors, the parts operated upon in one department pass right along to an elevator. The time saved is extremely valuable, and a large amount of money is thereby saved in production.

The heart of the person who originally planned the phrase, "A place for everything and everything in its place," would rejoice could he make a tour through the rough and finished stock rooms at the Pierce-Arrow plant. There is always a complete list of the stock in hand, and a plan of where every part may be found. In the rough stock department the larger castings, such as flywheels and cylinders, engine bases, and gearcases have their own floor spaces, as do the forgings. Smaller forgings and castings are kept in bins, while the smallest parts are stored in shut steel boxes on shelves. Bars and rods of steel and brass have their own racks, each one labeled, and sheet metal is stacked on the top of the racks. In the finished stock room almost all the parts are kept in steel drawers.

In the Inspection Room Each Workman Has a Desk and Is Seated at the Careful Work of Checking Up Parts Dimensions.

MORE TAXICABS AND STILL MORE.

SPRINGFIELD, MASS., April 26.—A shipment of fourteen taxicabs to the Phillips Automobile Company, of St. Louis, has just been made by the Atlas Motor Car Company, of this city. These newcomers, with the cabs now owned by this company, will make a total of more than twenty Atlas cabs by one company, with more to follow. The two-cycle engine with which they are equipped had much to do with the adoption of this make, as the simplicity, ease of starting and practical indestructibility appeal to the man who pays the bill.

The 1909 cab equipment has the two-cylinder, two-cycle, 20-horsepower engine, equipped with Atwater-Kent ignition system, sight-feed Hancock oiler, gear-driven instead of belt-driven; improved carbureter, with gasoline adjustment on dash; pump circulation, which eliminates all possibility of overheating the engine under the most severe conditions; gear-driven fan, which makes it possible to run engine at highest speed when the car is standing still, without any steaming of the water. A high-grade steel frame is used, the width of which in front is narrowed up three inches to allow maximum cramp of the front wheels and which adds greatly to the appearance. A very superior sliding gear transmission has been developed, which combines all of the good qualities of both the sliding gear and planetary type of transmission.

MAXWELL ENGINE FOR MOTOR BOAT.

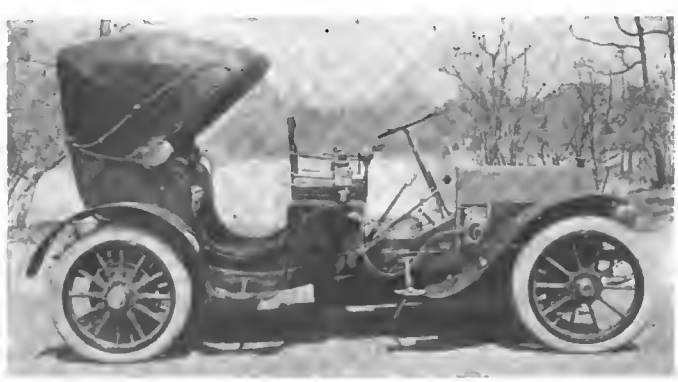
The defeat of the *Dixie II* at the Monaco race meet has stirred up the American motor boat builders, and one of the immediate results is the announcement of a number of new boats. One of the first is to be the *Maxwell-Driscoll*, so named after the engine and the owner. The latter, R. J. Driscoll, of the Tarrytown Yacht Club, is having a boat of the same size as the *Dixie II*, 12 meters, built at the plant of the Hudson River Motor & Boat Works, of Tarrytown.

This will be equipped with a special motor from the works of the Maxwell-Briscoe Company. The number of cylinders to be used is 12, and the power rating is given out as 200. Bore and stroke have not been publicly announced, but the whole construction will be special, to match the especially light hull.

The new boat will be entered in all of the speed boat contests for which it is eligible, including the Fulton celebration and international races.

PALMER-SINGER MODEL FOR SUMMER USE.

The Palmer-Singer victoria is one of the most attractive summer models yet seen in New York. The body follows the conventional lines of horse-drawn carriages, adapted, of course, to its different mounting. It will recommend itself very strongly to people who are just giving up horses for city use. The chassis is of 30 horsepower, insuring considerable touring ability; the double-drop frame allows the body to be hung very low and lends itself to the graceful curves of the design. An extra body of the enclosed type, for winter use, can also be furnished.



Thirty-Horsepower Palmer & Singer Victoria.

WILKINSON ADVOCATES SPHERICAL HEADS.

In a recent discussion of the cooling effect of having the interior of the cylinders of an automobile engine approach as nearly as possible the spherical form, thus exposing a minimum of surface to combustion, John Wilkinson, chief engineer of the H. H. Franklin Mfg. Co., said:

In order to keep the temperature of the cylinder walls of a gasoline automobile engine within working limits the design must be such as to lessen the heat allowed to enter the walls or increase that carried off, or both of these results must be accomplished. Getting less heat into the walls involves one of the fundamental principles of the economy of the gas engine and is best accomplished by reducing the internal surface exposed to combustion to a minimum, which means principally designing the combustion chamber so it will be as nearly spherical as possible.

If the internal surface is less, the less the incoming charge is heated and the less heat is lost to the cylinder walls; therefore the greater the power and efficiency the less heat it is necessary to carry off from the walls to keep them at a working temperature.

This fact does not seem to be well recognized, as we still see engines built with the valve pocket on each side of the cylinder. The internal surface exposed to heat at the time of explosion in a four-inch by four-inch motor, with a semi-spherical cylinder head, is about 38 square inches; in the same motor with a valve pocket on either side of the cylinder it is about 74 square inches, and a good part of this surface has to be left rough. It is evident that the Jacket loss must be much greater in the last instance.

Engines with a hemispherical head show a gain of 25 per cent. in power and efficiency over the type with a valve pocket on each side. This type of cylinder head may also be machined smooth on the inside to reduce its absorbent effect to a minimum.

The concentric valve on the Franklin motor cars was designed to fit in exactly with air-cooling, dome-head, large-intake-valve construction, which would give increased power, increased efficiency and increased cooling ability. This construction also means a shape of cylinder and valves in which expansion from heat is equalized in every direction, preventing heat warping of parts.

FAL-CARS APPEAR ON CHICAGO STREETS.

CHICAGO, April 26.—The newest of Chicago-made automobiles, the FAL-Car, successor to the Reliable Dayton, is now active in the automobile affairs of the city. Demonstrations are being made, and H. R. Averill, the sales manager, reports that 20 cars will be ready for shipment by May 10. They are built in three styles, touring car, toy tonneau, and roadster, all on one type of chassis, with a four-cylinder, 30-horsepower motor, and selling for $1,650. The firm intends to move from its present quarters at 15 North May street, to a larger plant on the south side of the city, so that the production for this year of 100 cars will be increased to 700 for the 1910 season. The important races and contests will be entered by the FAL-Car, in its classes.

ONE COMMERCIAL VEHICLE DEMONSTRATION.

HARTFORD, CONN., April 26.—An excellent demonstration of commercial car efficiency was afforded by S. A. Miner, who has been utilizing second-hand cars in delivery wagon service. The demonstration was made for the benefit of a large local grocery house. The commercial vehicle was loaded at the same time as were the horse vehicles. Thirty-six boxes of groceries of varying weights were loaded on the Knox car, and, according to the driver of one of the horse teams, it would require 3 to 3½ hours to deliver. The Knox did the trick in 1 hour 5 minutes.

KEYSTONE SIX IS NAME OF NEWCOMER.

NEW CASTLE, PA., April 26.—In the next fortnight the Keystone Six, of 60-horsepower, will be presented by the Munch-Allen Motor Car Company. This newcomer will have a double ignition system, including Bosch magneto, disc clutch, sclective transmission, 121-inch wheel base and use 36 by 4-inch tires. The car will sell at $2,250, completely equipped, and its makers will give a guarantee for one year. The company intends to put out about 250 cars of the 1910 model. It was erroneously printed that the car would be known as the Pennsylvania No. 6.

Told in the Progress of the Industry

Rapid Expansion of Oklahoma Motor Car Company.—An example of the growth of the great Southwest is that of the Oklahoma Motor Car Company, of Oklahoma City. This concern, dealing in automobile supplies for the past two years in Oklahoma, has outgrown its facilities, and has opened a branch, larger than the home office, in Dallas, Tex., from which the Lone Star State will be supplied with accessories. This will be conducted under the name of the Southwestern Automobile Supply Company, at 349-351 Commerce street. A third establishment under the title of the Overland Automobile Sales Company has been opened in Dallas, and it will have the agency for the Overland and KisselKar in Texas and New Mexico. The three concerns are identical in ownership, and President Will T. Brown and General Manager T. B. Funk will have managers in each place.

Waverly Electric in Rural Mail Service.—The use of electric automobiles in city mail delivery service is not uncommon, New York having added three to its equipment recently, but in rural work this type of propulsion has been less frequently used. On route 2, out of Manchester, N. H., Mark T. Hoffman uses a Waverly road wagon of 1905 design. He writes to the Waverly Company: "I am about to put my Waverly electric in commission. This is the fifth summer of five months' use each; but is second season of a new Exide battery which was charged 100 times for the 24-mile trip. The battery did wonderful work, making the trip of 24 miles with hills of 1,000 feet in all, on two volts, or 64 at start and 62 at finish, even on rainy days. This was over the rural U. S. mail route with 50 stops."

Business Men Recognizing the Motor Truck.—The filing of an order for a 5-ton American motor truck by the American Motor Truck Co., of Lockport, N. Y., for the Robert MacKinnon Co., Little Falls, N. Y., one of the largest knitting concerns in that State, tends to show that business men are beginning to understand the difference between the requirements for a commercial car and a pleasure car. This car will replace three heavy trucking teams and wagons, and is built for service alone. It has a four-cylinder 60-horsepower motor, with extra large and long bearings. Its piston area is greater than that of a similar powered pleasure car motor and the revolutions are slower.

New Chicago Home for Premier.—Webb Jay, Chicago agent for the Premier Motor Car Company, has let contracts for the construction of a reinforced concrete building at 2329 Michigan avenue. This will be rushed to completion so that it may be occupied by mid-summer, and will be the western distributing headquarters for the Premier. The first floor will be arranged for the offices, the salesrooms, and garage; the second for making tops; and the third for a stock room and repair shop. A 20-year lease was taken and the structure will be a model of its kind.

Ferry Route Across the Sound.—A short cut for automobilists from points in Westchester County, New York, and in lower Connecticut, to Long Island has been proposed by the Oakland Steamboat Company, Inc. It is planned to run boats at frequent intervals between Rye and Seacliff, and between Stamford and Cold Spring Harbor. Its regular service is between New Rochelle, Rye, Oakland Beach, and Stamford. The ferries across the sound would cut off a great distance now traveled through New York City.

Baker School of Instruction.—The Baker Motor Vehicle Company recently held a school of instruction at its factory in Cleveland, under the direction of its chief electrical engineer, Emil Gruenfeldt, at which representatives of nearly all the Baker agencies throughout the United States were present. Mr. Gruenfeldt gave a series of talks regarding the mechanical construction, equipment, maintenance, care of batteries, etc., and thoroughly demonstrated the new Baker electric models.

M. & W. Tires on Pathfinder.—Tire equipment will play an important part in the Glidden tour this summer, and the Morgan & Wright Company, of Detroit, is pleased by the fact that the E-M-F car which is making the pathfinding trip is equipped with M. & W. tires. These have been standard equipment on E-M-F, and the automobile builders made no change for the hard run on the almost impassable spring roads.

Reo Increases Capital.—The capital stock of the Reo Motor Car Company, at Lansing, Mich., has been increased from $1,000,000 to $2,000,000. About $250,000 will be spent at once in enlarging the capacity of the factory, so that 10,000 machines a year may be built instead of the 7,000 as at present. The plant is now shipping 50 automobiles a day to all parts of the country.

Electric Sightseeing Chairs.

The two-passenger motor-propelled chair, which will be used about Belle Isle, Detroit's chief park attraction, the coming summer. These cars are capable of a speed of eight miles per hour.

Fal Motor Company Plans Southern Assembling Branch.—To insure more rapid delivery of cars in the South, the Fal Motor Company, the recent successor of the Reliable Dayton Motor Company, is planning to have a branch in Memphis, where some of its cars will be assembled. The parts will be shipped from the machine shops in Chicago.

Winton Six Popularity Felt at Factory.—The popularity of Winton Sixes has necessitated a 12-hour day in the machine department and an extension of the assembling department, whereby floor space of about 50 per cent. will be added. Work is going forward and the addition will be ready for use within two weeks.

Vanderbilt Buys Motor Plow.—George W. Vanderbilt is equipping his estate at Biltmore, near Ashville, N. C., with a number of automobiles and other motor-driven vehicles for farm use. He has already installed a motor plow, and a provision wagon.

Weston-Mott Company Enlarges Factory.—The Weston-Mott Company of Flint, Mich., has announced that it will shortly begin the erection of a new factory. The contract has been awarded to the Vinton Construction Co., Detroit.

Dallas, Tex., Dealers Organize.—The Dallas Automobile Dealers' Association has been organized with the following officers: President, M. A. Sacksteder; vice-president, M. B. Burwell; secretary-treasurer, J. B. McGraw.

Covert Motor Car Company in Detroit Field.—The Covert Motor Car Company has begun the manufacture of a medium-priced touring car with a four-cylinder, two-cycle engine.

D.H.K. Company Formed in Detroit.—A new company has been formed called the D.H.K. Motor Car Company, to build light runabouts to sell under $500.

IN AND ABOUT THE AGENCIES.

Rainier Opens Philadelphia Branch.—The Rainier Motor Company has opened a branch in the Quaker City under the management of J. Knight Neftel. A location at Chestnut and Eighteenth streets, well away from the automobile row, has been secured. Mr. Neftel was formerly sales manager of Smith & Mabley, of New York, and later Paris representative of the same concern.

Firestone, St. Louis.—The two branches of the Firestone Tire & Rubber Company have been consolidated into an enlarged store at 2230 Olive street. The stock of pneumatic tires formerly carried at 3910 Olive street has been moved to the new headquarters, which, until this time, has handled solid tires only. O. O. Petty is the manager of the consolidated branch.

Penn Auto Supply Co., Atlantic City.—The Penn Auto Supply Co., of Philadelphia, as a convenience to its many patrons, has opened an Atlantic City branch at 2006 Pacific avenue, that city. W. C. Price, formerly connected with the Hartford Rubber Co., will manage.

Packard Testers in Role of Good Samaritans.

Detroit is well acquainted with the Packard testing corps under Will Birmingham. It is seldom that one of them is very far away in case of trouble. The other day a horse-drawn wagon, delivering some heavy bars of steel, tipped over turning into the factory yard. Just then Birmingham happened along, and it was the work of but a few minutes to hitch onto the back end of the load and jerk it into place.

Hupmobile, Philadelphia.—To complete its line, now consisting of the National and Rambler cars, Manager Geo. G. Brownlee, of the Tioga Automobile Co., of philadelphia, has closed a deal for the local agency of the Hupmobile, a Detroit product listed at $750.

Rapid, Detroit.—The Rapid Motor Car Company, of Pontiac, has opened a garage and salesroom at 467-469 Woodward avenue, under the management of C. S. Bugbee.

TAXICABS AND TRANSIT.

Seattle, Washington.—The Seattle Taxicab Company, which has been operating cars in this city since March 1, now has 10 gasoline machines on the streets, and will continue to increase its service by six cars each week until enough are on hand to supply the demand. The service has proved very popular.

New York City.—A syndicate has made application to the public service commission and the board of estimate for a franchise to establish a bus service on the new Queensboro bridge, pending the installation of trolley service. The bridge is a mile and a quarter long.

PERSONAL TRADE MENTION.

N. H. Van Sicklen, Sr., the founder and former proprietor of *Motor Age*, well and favorably known throughout the Middle West, has announced his newest venture. This is in connection with the Nadall-Van Sicklen Manufacturing Company, of Chicago, of which he is secretary-treasurer. The business has increased to such an extent that new and larger quarters were a necessity. These were secured at 1233 Michigan avenue, where Nadall demountable rims will be handled.

Frank J. Campbell, whose Personal Advertising Service in Detroit was conducted at 242 Griswold street, has moved to more commodious quarters in the Trussed Concrete Building, and has changed the name of his organization to the Campbell Advertising Service. His move has placed him on "advertising square," so-called by the outside fraternity in referring to the neighborhood of the Federal Building.

Horace B. Hills, Jr., has assumed the management of the New York branch of the Royal Tourist Car Company, in its new location on Broadway at Sixty-second street. He will continue his business as agent for the Royal Tourist in Philadelphia. Max Greene, formerly associated with the White, and Chalmers-Detroit cars, will be associated with Mr. Hills in New York.

Fred J. Titus, former well-known champion bicyclist, who has been for the past five years one of the head salesmen for the Harry S. Houpt Co., of New York City, has completed arrangements to establish an agency for the Herreshoff and Houpt cars in New Jersey, at 213 Clinton avenue, Newark.

William E. Botto has accepted the position of general manager of the automobile and garage business conducted by George C. John of New York. in American Mors, Inter-State, and Marmon cars. Mr. Botto recently resigned from his position as sales manager of the Palmer & Singer Mfg. Co.

William W. Fickling, who has been prominently identified with New York second-hand automobile houses, has been engaged to manage the second-hand business of the Automobile Sales Corporation, of Philadelphia.

Robert H. Turner, formerly on the advertising staff of the Philadelphia *Evening Telegraph*, has joined the sales forces of the branch of the Firestone Tire & Rubber Company there.

C. Louis Fitzgerald has been appointed manager of the Newark, N. J., agency for the Packard. Mr. Fitzgerald has been connected with the New York Packard branch.

OBITUARY NOTICES.

Baron Edouard de Turckheim, the head of the de Dietrich firm, with works in Niederbronn, Germany, and Luneville, France, died at the Chateau de Dachstein, Alsatia, recently, aged eighty-one. Two surviving sons, Baron Adrien and Baron Eugene. are at the head of the main works at Luneville.

H. Spencer Lucas, a trustee of the firm of John Lucas & Co., the Philadelphia oil and soap makers, died at his home city on April 16.

PROVIDING, NOT PREVENTING.

In the advertisement of the General Accumulator & Battery Company, Milwaukee, Wis., appearing in the April 22 issue of THE AUTOMOBILE, the inadvertent use of the word "preventing" so distorted the meaning that the reading was just the opposite of what was intended. The substitution of "providing" makes it read as it should, viz.: "Current discharged through transformer, making high tension, at the same time providing dual system," etc.

REGARDING ENGINEER LANDAU.

The following communication received from Asher Golden, of Landau & Golden, New York City, is self-explanatory:

"We wish to correct a notice in your last issue to the effect that David Landau has been appointed chief engineer of the Palmer & Singer Mfg. Co. We were retained about a year ago by the Palmer & Singer Mfg. Co., as consulting engineers, and have done considerable work for them in this direction. Owing to the recent resignation of Oscar Stegman, the Palmer & Singer Mfg. Co. simply called in Mr. Landau to take complete charge of their engineering department. Mr. Landau is not on the Palmer & Singer pay-roll."

LONG SERVICE OF FACTORY MEN.

Length of service of the men in a big factory plays an important part in the success achieved in raising production to a high standard, and recently an official of the Pierce-Arrow Motor Car Company requested a list of the factory heads and foremen, with the number of years' service of each. In all, the lists made up show that there are 46 men who have charge of the work of production, the highest in rank being the vice-president, whose duties includes the factory management, and from him running down the line to the foremen. The total term of years these men have been with either the Pierce-Arrow Motor Car Company or its predecessors foots up to 442, making the average connection with the company 9.61 years. The man who holds the record for long service is Henry May, vice-president and general manager, who went with the firm in 1873 and has remained with it ever since, a period of 36 years. One foreman has been with the company 28 years and two others for 21 years, while a number have worked continuously for 10 to 17 years.

RECENT INCORPORATIONS.

Mackenzie-Walton Company, Providence, R. I.—To manufacture seamless wire tubing for automobiles anad other mechanical purposes. Will erect brick factory at Pawtucket avenue and Geneva street. A. J. Thorley, J. M. Mackenzie and Joseph Walton are members of the firm.

National Lamp and Brass Manufacturing Company, Chicago.—Capital, $3,500. To manufacture auto lamps and brass goods of all kinds. Incorporators: G. W. Killelea, R. H. Wilson and H. Horner.

John J. Gibaon Company, Buffalo.—Capital, $20,000. To manufacture motors, engines, machines, cars, automobiles and wagons. Incorporators: J. N. Gregory, E. G. Thompson, George Roughead, Jr.

Automobile Owners' Protective Association, Camden, N. J.—Capital, $100,000. To manufacture automobiles and protect owners. Incorporators: F. J. Curran, J. U. Clarke and T. F. Curley.

Jewel Electric Company, Chicago.—Capital, $15,000. To manufacture and deal in automobiles, electrical supplies, etc. Incorporators: R. I. Phillips, M. C. St. John and M. C. Diller.

Morgan Avenue Garage, Brooklyn, N. Y.—Capital, $7,000. To deal in automobiles, operate a garage, etc. Incorporators: J. A. Blanchfield, W. J. Blanchfield, Samuel Newman.

Taxi Motor Cab Company of Boston.—Capital $375,000. To do a general automobile business. Incorporators: President, E. M. Davenport; treasurer, A. W. Pope.

East Side Auto Company, Attleboro, Mass.—Capital $20,000. General automobile business. President, C. J. Adams; treasurer, A. N. Cooper; clerk, G. L. Adams.

Knickerbocker Automobile Company, Wilmington, Del.—Capital $100,000. Incorporators: E. L. Squire, G. W. Dorsey, Jr., Albert Bird.

Miller Brothers, Amesbury, Mass.—Capital $50,000. To do a general automobile business. President, T. C. Miller; treasurer, S. Anderson.

Brush-Chicago Motor Company, Detroit, Mich.—Capital $11,000. Incorporators: Frank Briscoe, E. D. Moessner, Paul R. McKenney.

Deluxe Motor Car Company, Detroit, Mich.—Capital $150,000. Incorporators: M. M. Kaufman, S. R. Kaufman, D. E. Kaufman.

Belnord Garage, New York.—Capital $18,000. Garage business. Incorporators: D. S. Loeb, Seymour Schampain, A. H. Vitale.

Durham Automobile Company, Durham, N. C.—Capital $50,000. To manufacture automobiles. Secretary, T. H. Lindsey.

Industrial Automobile Company, Elkhart, Ind.—Capital $75,000. Incorporators: T. J. Shanahan, W. S. Long, L. D. Hall.

Albert Sterne Motor Company, St. Louis.—Capital, $15,000. Incorporators: Albert Sterne, Max L. Weiss, Leonard Fassett.

American Reversible Motor Company, Boston.—Capital, $50,000. President, A. C. Day; treasurer, G. M. Power.

Wakefield Auto Company, Albany, N. Y.—Capital $5,000. To operate taxicabs and rent autos.

Kalamazoo Carbureter Company, Kalamazoo, Mich.—Capital increased from $7,500 to $25,000.

L. B. Repair Company, New York.—Capital, $10,000. To deal in and repair automobiles.

The Perth Amboy Garage Company, Perth Amboy, N. J.—Capital $50,000.

NEW AGENCIES ESTABLISHED.

Peerless, Stoddard-Dayton, Birmingham, Ala.—Drennen & Company, Avenue C and Twentieth street. Manager of automobile department, George B. Kelly; manager of mechanical department, A. D. Wood.

Detroit Electric, Boston.—Messrs. Rommelfanger and Binney, 323 Columbus avenue, trading as the Boston Electric Garage.

American Simplex, New York City.—Grant-Isbell Auto Company, 1666 Broadway; Ben W. Rickert, sales manager.

Hupmobile, Baltimore, Md.—Joseph Weisenfeld, in addition to the Oakland.

Lozier, Syracuse, N. Y.—The Amos-Pierce Auto Company, 215 James street.

Haynes, Rockford, Ill.—H. R. Hill, for Winnebago county.

E. M. F., Morristown, N. J.—W. B. Smith

SELECTED AUTO PATENTS.

Issue of April 20, 1909.

918,550. Rubber Vehicle Tire.—Chester O. Henderson, Dayton, O. Filed Sept. 21, 1908.

918,607. Carbureter.—Clarence B. Sturges, Scranton, Pa. Filed April 22, 1907.

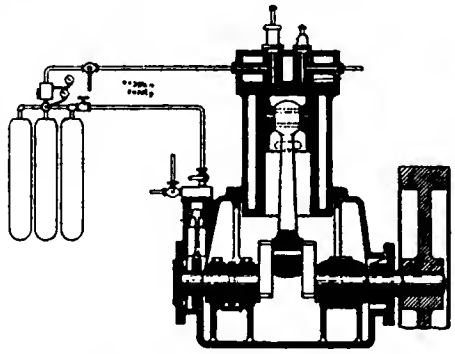
918,621. Change Speed and Reversing Gear.—Luis Wirtz, Bilston, Eng. Filed July 6, 1907.

918,644. Vehicle Wheel.—Lloyd W. Barnhart, Van Wert, O. Filed April 11, 1908.

918,657. Three-Speed Transmission Gearing.—Robert W. Coffee, Richmond, Va., assignor to Lewis M. Keizer, Baltimore, Md. Filed May 16, 1906.

918,658. Power Transmission Gearing.—Robert W. Coffee, Richmond, Va., assignor to Lewis M. Keizer, Baltimore, Md. Filed June 25, 1906.

918,679. Internal-Combustion Turbine.—Paul Krause, Babylon, N. Y. Filed Oct. 10, 1907.



Sabathe Improved Cycle Scheme.

918,680. Emergency Stop for Motor Vehicles.—Paul Krause, Babylon, N. Y. Filed Nov. 12, 1907.

918,704. Internal Combustion Engine.—Louis G. Sabathe, Paris. Filed Aug. 30, 1906.

As the cut shows, this inventor is endeavoring to improve upon the process followed out in the ordinary engine. He does this by introducing into the cycle a portion of the compressed burned products, simultaneous with the injection of fuel, and followed by the introduction of a gas capable of supporting combustion. The arrangement is certainly a complicated one.

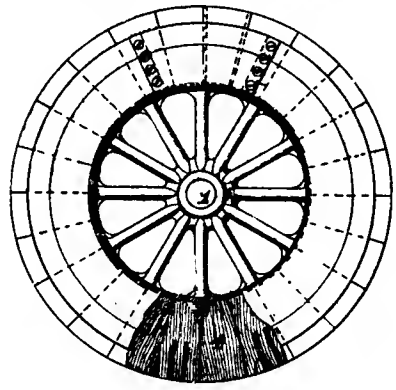
918,726. Spark Plug.—Franz Barthl, Far Rockaway, N. Y. Filed Aug. 12, 1907.

918,820. Tire for Vehicles.—David P. Boyd, Toledo, O. Filed Nov. 23, 1907.

918,846. Tire.—F. J. Gostlin and L. Mueller, Jr., Akron, O. Filed Feb. 5, 1907.

918,936. Transmission Gearing.—Dixon E. Washington, Chicago. Filed March 26, 1908.

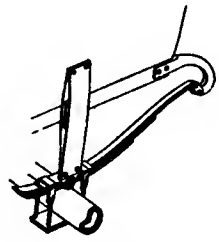
918,945. Wooden Rim Wheel.—Herman F. Ball, New York City, assignor to American Locomotive Company. Filed Aug. 27, 1908.



Ball's New Truck Wheel.

This wheel is more suitable for truck use than pleasure cars, and is doubtless intended to be tried upon the trucks now being brought out by this company. This is a subject that has been tackled before and without success, so it is to be hoped that the present trial will not meet with the same fate as its predecessors. For heavy truck tires, the solid rubber tire represents too high a depreciation figure, hence the various attempts to replace it with something less expensive, of which this is one.

918,987. Shock-Absorbing Device for Vehicles.—Claud H. Foster, Cleveland, O. Filed Jan. 21, 1907.



Foster Shock Absorber.

Foster's various inventions are all good, and the appearance of the latest seems to imply that it is good, too. It has been on the market for some time, so will not be described in detail. A pair of tapering side plates carry between them a sliding member which is attached to the car. The rise and fall of the sliders is resisted by the taper sides of the fixed member.

918,996. Cage for Ball Bearings.—Ernest Geshke, Charlottenburg, Berlin, Germany. Filed Nov. 20, 1907.

919,101. Clutch Mechanism.—C. L. Whaley, Augusta, Ga. Filed Dec. 14, 1907.

919,104. Valve Actuating Mechanism for Explosive Engines.—Alex. Winton and Harold B. Anderson, Cleveland, assignors to Winton Motor Carriage Company, Cleveland. Filed Sept. 8, 1908.

919,123. Spark Plug.—J. W. Brown, Jr., Camden, Ark. Filed Sept. 23, 1908.

919,174. Combined Turbine and Internal Combustion Engine.—John Hutchins, Moorfields, London, Eng. Filed Jan. 22, 1907.

919,276. Spark Plug.—Theodor Winestock, Stuttgart, Germany, assignor to Otto Charles Winestock, Perkinsville, Vt. Filed April 30, 1908.

Assembling Department of the E-M-F Factory Showing Completed Cars.

Information for Auto Users

An Indestructible Wrench.—The increased demand for socket wrenches has brought out a number of high-grade devices of merit. Chief among these is the product of the Rex Wrench Company, of Boston. This is a drop-forged article of such workmanship and material that the makers warrant every part of it against ordinary breakage and actually replace parts which break. The working parts of the handle and the fork heads are drop-forged from a high carbon steel, and are case hardened. The sockets are steel castings by a new process that renders them very tough, so much so as to be unbreakable. In addition, a patented, telescopic, reversible handle may be had if desired.

REX WRENCH HANDLE.

As put on the market, the wrenches are in sets, varying from eight socket heads upward as high as one wishes to go. For instance, a set for all purposes, and especially adapted for motor boats, motors, and complicated machinery, is put out in a handsome oak box, at $12. This set consists of the patent handle, screw driver, eleven fork heads, and eight hex socket heads. This will take all nuts, bolts, and cap screws, whether square or hexagon, from ¼ inch up to ⅞ inch. These are furnished with a blue mottle finish, but if nickel is desired, it may be had at a slight additional cost. The handle is worthy of special mention, being complete in itself, extended or closed by the pressure of the hand. The sockets may be adjusted to any position instantly, and may be taken apart with ease and speed. When so taken down, the length is reduced from 14 to 8 inches.

A SET OF REX WRENCHES.

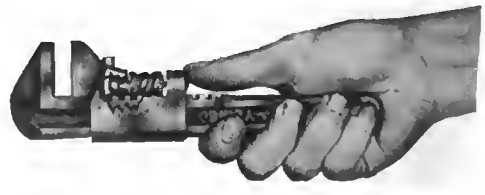
Stein Automobile Tires.—Several features are embodied in the clincher tires made by the Stein Double Cushion Tire Company, of Akron, Ohio. Among these are the absence of lugs, the quality of not creeping, and the formation of the clinch. The beads, instead of ending, as is general practice, with a space between them on the interior when in place upon a rim, in the Stein tire overlap, thus forming a double cushion for the tube, preventing the entrance of any water or dirt, and keeping the entire volume of the inner tube above the rim. The design is patented. The shoes have been thoroughly tested during three years of road work, and with their wrapped-tread construction have shown that the quality is of a high standard, nothing but the best of materials—old, fine, Para rubber and Sea Island cotton—being used. With the bead or clincher overlapping, the tube does not come into contact with the rim and, it is claimed, will not pinch or chafe, remaining naturally round. The strain is equally divided upon the walls. The valve stem holds the entire shoe in place, there being no lugs, but the system prevents the tire from creeping. Stein tires are made in all popular sizes, and will fit any clincher, detachable or universal rim.

STEIN DOUBLE CUSHION TIRE.

Banker Wind Shield.—Spring, the windy season, is the time for wind shields, and motorists, now getting out their cars, will do well to consider this needful accessory. The Banker Wind Shield Co., Pittsburg, Pa., are out with an extra fine product in this line, consisting of the No. 1 shield, which is not divided, and No. 2, which is double folding. The latter is parted in the center, below the line of vision. There are no strips of metal across the center of the shield. In their place the plate-glass is supported on shelves extending from the frame. The upper glass folds on strong, extra heavy, piano-type hinge, and is held in place by a special clamp, which, with the rubber buffers, prevents rattling. The glass is 1-4 inch thick and of French plate. The frame is made of a single piece of 7-8-inch stock, with a 3-8-inch groove. The glass sets in this on a channel-shaped rubber, without bolts or screws to fasten it. The rubber and the absence of metal fastenings insures the total elimination of noise, heretofore a big objection in wind shields. All clamps, bolts, hinges and other metal parts are of brass, highly polished, in this way securing the distinctive appearance which discerning motorists seek after so eagerly. The telescoping tubes are of 3-4 and 5-8 inch tubing, which insures lightness and rigidity. They are fastened securely to the shield by a special clamp, so as to be held in a vertical or horizontal position as desired. Each end of the tubes is provided with a ball and socket joints with more rubber buffers to prevent rattling. All wood used in the construction is of selected stock, either of mahogany or walnut, as desired. This is given an extra fine piano finish. It can be fitted to any car. Being very simple, this is the work of but a minute.

BANKER NO. 2 WIND SHIELD.

Yemco Quick-Adjustable Wrench.—Wrenches that can be operated by automobilists when in inaccessible places about a car are exceedingly handy. The York Electric & Machine Company, of York, Pa., has been marketing successfully in recent years the Yemco wrench, which can be used with one hand simply by pushing a little pin in the sliding jaw. Its appearance is similar to that of any other wrench, 8 inches long, made of dropped-forged, case-hardened steel, and it can be moved to any hundredth of an inch and will hold at that point without further manipulation. In using it, the jaw is pushed up with the thumb, first slipping the jaws open, hooking one over the nut, push up the other one and releasing the pin.



YEMCO WRENCH LOOKS LIKE ANY OTHER.

Marble System of Vulcanizers.—A method of repairing automobile and other pneumatic tires that is entirely different from any other now in vogue is that of the Marble system, manufactured by the M. E. Haywood Manufacturing Company, of Indianapolis. The principle is that of local application, heating only the part of the tire that needs curing, so that the remainder is not liable to deteriorate. If a tread is to be put on, only the raw material going into it is heated, and the bead and side walls are scarcely warmed. The plant is composed of the following parts: three inside patch vulcanizers, by which a broken shoe is repaired from the inner side and becomes stronger; three retreading vulcanizers, suited for tires ranging in size from 28 by 2½ inches to 36 by 5, taking up one-third of the circumference of the tread; one side wall and rim cut vulcanizer, which applies the heat and pressure directly to the parts to be cured, such as torn beads and sides; one tube arm, which will accommodate at least twelve tubes at once, clamped under pressure; one motorcycle vulcanizer for motorcycle tires; two patching vulcanizers for all size tires and taking up to 20 inches in length; one tread roller, to roll stock under greater pressure than by hand; complete frame of piping with globe valves and steam gauge, serving also as a steam line; and pads, clamps and complete sets of tools. This outfit enables a small dealer to have a complete tire repairing plant in a unit.

MARBLE VULCANIZER READY FOR USE.

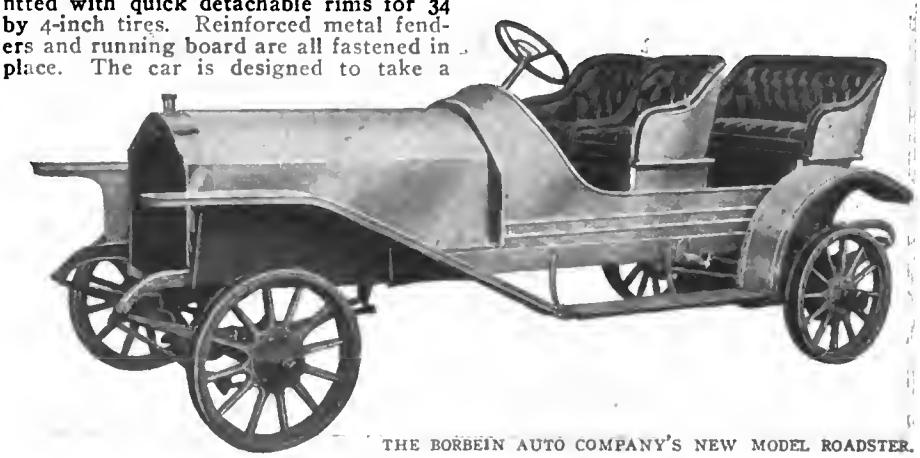
Permanit for Healing Punctures.—A preparation which may be placed in tires to heal punctures and prevent porosity is being imported by the Adolf Karl Company, Inc., of Newark, N. J., and is sold under the name of Permanit. According to the officials of the firm, this material is a powder, there being no liquid form to fill the valve, and when a nail or something else sharp forces through the casing and tube, the powder acts to fill the space and prevent deflation. It can be used in any size tire, from that of a bicycle to the largest ones for automobiles, and numerous letters of commendation of it are received.

Universal Auto-Tire Remover.—This is more of a time saver than anything else. It does away with the use of a hammer in removing tires, thereby protecting and keeping in good condition rims, tubes, casings, fingers, and tempers. Being very simple, any one may use it. The natural strength of the tool makes it impossible to break it. Being easily adjusted, it can be made to fit any size tire or rim. The principle upon which it works is that of the compound lever. It is made in San Francisco.

AUTO-TIRE REMOVER.

Borbein's New Roadsters.—A new model of roadsters, ready for the power plant, is being built by the Borbein Auto Company, of St. Louis. The running gear and body are sold complete, the purchasers having only to install the motor and transmission and supply tires. The latest type is made with seats for four, all set low to increase ease of riding, with high cushions and upholstered with dark-green leather. The front seat is divided and has a metal shield from the rear of the dash to the front of the rear seat. The rear seat, wide enough for two passengers, is not divided, making the complete body a surrey in style.

The front axle is of the I-beam type, 2¾ inches high, with annular ball-bearing spindles; the rear axle is of the floating type for shaft drive, with its gears in the ratio of 2½ to 1. Both internal and external brakes are furnished; the wheel base is 120 inches, and the tread standard 56. The artillery wheels are fitted with quick detachable rims for 34 by 4-inch tires. Reinforced metal fenders and running board are all fastened in place. The car is designed to take a four-cylinder engine of medium size and any type of transmission; sold with one coat of lead paint, and including radiator, hood and steering gear. The Borbein Company builds all styles of running gears, bodies, axles and wheels.



THE BORBEIN AUTO COMPANY'S NEW MODEL ROADSTER.

Steering-Wheel Switch.—The awkward reaching for the switch on the dash or under the seat will soon be a thing of the past, if autoists appreciate the device just brought out to dispense with that. It is no more nor less than a properly designed switch, intended to go on the steering wheel and be operated in that position by the driver, without other movement than that of the fingers. It is intended to go on the right hand, underside of the wheel.

Four positions are provided as follows: Off, battery, magneto, magneto and battery together. The latter allows of its use on cars with two separate ignition systems, and is no hindrance on cars with a single system. The size is small, being but one and a half inches in diameter. It is entirely waterproof, and dustproof as well. The construction is of a high class, being entirely of brass. The method of fastening is by means of a bracket under one of the arms. The controlling lever may be removed at will, making the car safe from interference during the driver's absence. There are but two wires used and these are encased in a flexible brass tubing, through which they pass to the magneto and battery.

It is manufactured by the Conn. Telephone & Electric Co., Meriden, Conn.

CONNECTICUT STEERING WHEEL SWITCH.

INDEX TO ADVERTISERS

Vol. XX New York—Thursday, May 6, 1909—Chicago No. 18

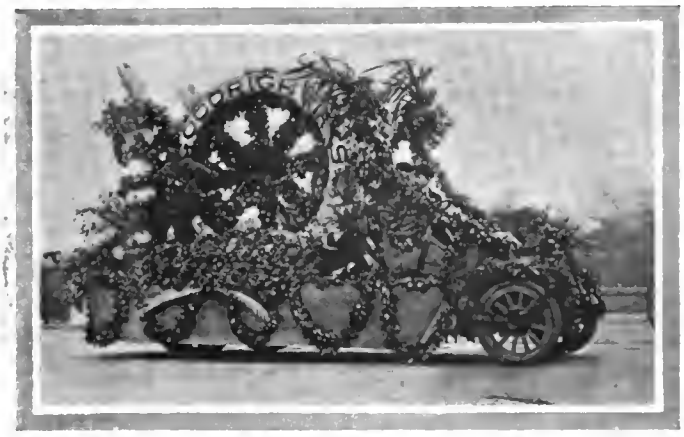
THE AUTOMOBILE

Told Thousands of Auto's Universality

TELLING to thousands in a comprehensive and practical manner the varied uses to which the motor-driven vehicle is now put, the automobile parade in New York City, Monday afternoon, served as a public demonstration of value and attracted widespread interest. Postponed from the preceding Saturday, because of the inclement weather, the event was favored with an ideal Spring day. Though the number of cars in line —310—proved disappointing, the procession adequately illustrated how the automobile now figures in the transportation of all kinds of merchandise, as well as for the carriage of passengers, individually and collectively.

Beginning with the light delivery wagon, carrying a load of a thousand pounds, and ending with the heavy five-ton truck dragging a loaded trailer with two additional tons, the commercial section showed cars suitable for any service that the demands of business might require. The public service vehicle had a good representation in taxicabs and twelve-passenger omnibuses, there being thirty of such vehicles in line.

Crowds Await the Parade Eagerly.—As early as 2 o'clock the sidewalks on both sides of Broadway were occupied by a thin line of spectators, and the numbers increased until there was hardly space for passage except by way of the street. Fifth avenue had its lines of spectators in considerable numbers, and it was estimated roughly that nearly 200,000 saw the parade



Goodrich Tires Were In Evidence in the Procession.

The Diamond Tire Float Was Well Designed and Chic.

Warner Auto-Meters Were Well Advertised as Usual.

Studebaker Closed Body Delivery Wagon in Parade.

from beginning to end. The crowds were thickest at Bretton Hall, on Broadway, where the coronation of King Guy and Queen Annette took place, and along Automobile Row, where noise-producing devices of all kinds served to pass away the time until the cars hove in sight.

Parade Delayed at the Start.—The coronation ceremony was delayed for a short time owing to the inability of King Guy to reach Bretton Hall on time because of difficulty experienced with the royal robes. Queen Annette was ready for the curtain bell. The coronation finally took place at 3 o'clock, General John T. Cutting performing the ceremony. There was little speech-making save a congratulatory address to the royal party on their popularity with the automobile public. The King and Queen then mounted their respective cars, and headed by a band of music started. Queen Annette, in a gown of shimmering green silk, rode in a Buick car, and had a throne in the shape of a seashell. The King's throne was mounted on a Stearns chassis and was bounteously decorated in red and gold. As the two floats pased up Broadway, the other cars swung into line from the side streets.

Historical and Racing Cars Form First Division.—The first division of the parade followed the royal cars and consisted of old models of well-known cars, and racing cars of the present day. Among the "old timers" was the 1893 model of the Haynes, running under its own power, and an ancient Columbia which was towed by an up-to-date car of the same make. The Grand Prix Benz racer and the Fiat Cyclone were also in line, the former being towed by reason of its inability to run as slow as the general pace required. A 1900 model Panhard, the Renault racer, and the hillclimb and straightaway winners were also in this division.

Many Makes of Cars Represented.—Following the historical and racing cars came the touring cars of present day models. There were attempts at decoration in the shape of American flags and bunting, and some of the cars were festooned with colored streamers and bombarded with confetti as they passed along Broadway. Taxicabs carrying crippled children from various institutions were included in this division, which numbered 230 cars. A number of foreign cars as well as the majority of American makes were represented, two of the former, the Nagant of Belgian manufacture and the Silent Knight Daimler being unfamiliar to the majority of spectators. The driver of the latter car was appropriately costumed in a suit of armor.

Decorated Cars the Feature of the Parade.—The decorated division was the third and the subject of much comment on all sides. Three cash prizes were offered in this division and twenty cars competed, all showing taste and ingenuity in their design. The Lozier car, with its body in the form of a horn of plenty and decorated with American Beauty roses and occupied by four beautiful women attired as Colonial Dames, was considered the most attractive and received the first prize of $500. A representation of Cleopatria's barge, decorated with white flowers and mounted on an Oldsmobile, received the second prize. The third prize was awarded to a Matheson float decorated with red roses and occupied by girls in Pierette costume.

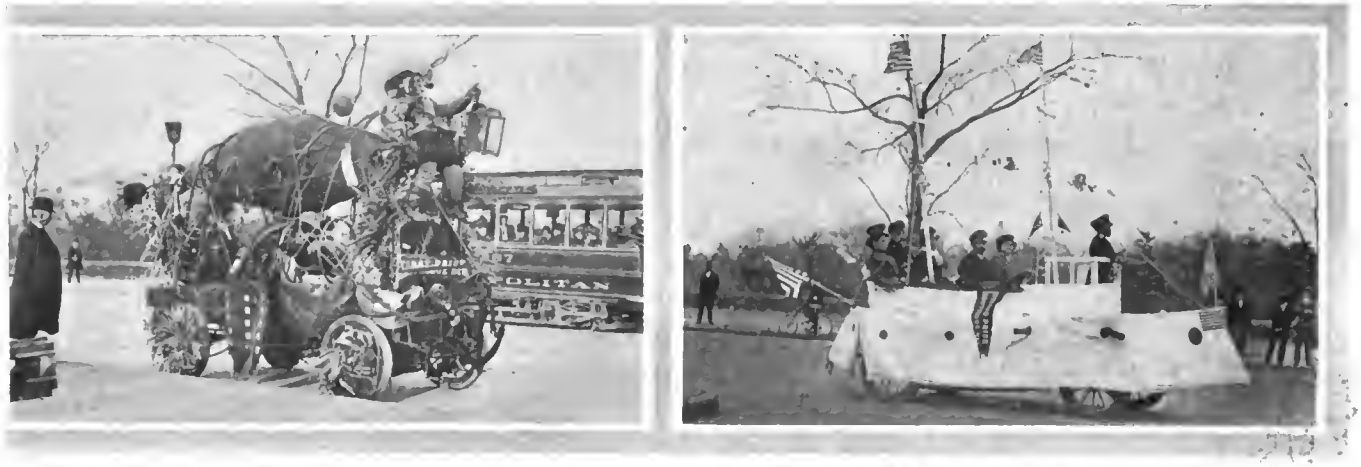
The grotesque cars created considerable amusement, especially the Desberon float representing Roosevelt on the prow of an airship with revolving propellor and surrounded by three men made up as African savages in the jungle. This float was awarded the first prize in the class. A Reo float, in the shape of a man-of-war and with a crew of negro sailors, took second prize in this division.

Michelin Float Makes Hit in the Commercial Division.—The commercial division brought out twenty cars of which three were awarded prizes. The float of the Michelin Tire Company made a decided hit and was accorded first prize, the Bibendum Twins on the elevated seat causing much laughter by their seemingly hilarious state. These figures represent the trademark of the Michelin Company. The Thermos float, built in the form of a bottle and apparently drawn by doves and driven by a young woman seated on the neck, mounted on an English Napier chassis, received second prize. The third prize in this division

A Heavily-Loaded Packard Truck and Double-Tip Couple Gear Truck That Were Features of the Commercial Division.

went to the Matheson Trophy car, in which trophies won by Matheson cars were shown on a large stage finished in white with columns at the corners, and a golden throne on which was seated a girl at the rear of the float. The Goodrich float with its huge tire in the centre and garlands of flowers and leaves, was also much admired, and the calliope car with its air compressing plant on a small trailer attracted attention by the music played at intervals along the route. The remainder of the sixty cars in this division consisted of trucks and delivery wagons, those of the daily papers making a good showing.

After the procession passed the reviewing stand at Ninety-second street and Broadway it continued to One Hundred and Eighteenth street, returned down the other side of the street to Forty-eighth and thence crossed to Fifth avenue, which was traversed to One Hundred and Tenth street, where the cars were disbanded. The judges made their choice of the winners on the stand, and the results were carried to Carnival Headquarters by messengers, so that the prizes were immediately given.



In the Grotesque Division "Teddy in Africa," and the Colored Marines in the Reo Warship, Were Leading Prize Winners.

One Gallon Efficiency Test to Be Held Friday.—The one gallon efficiency test postponed from Friday of last week will be held to-morrow (Friday). The results will be figured on a ton-mile basis. A radical cut in the fee, and the personal solicitation of entries by the interested and efficient committee, has resulted in a large increase in the number of entrants.

The Effective Tire Displays by Representative Manufacturers in the Commercial Division Showed Their Progressiveness.

The Michelin Bibendum Twins.

King Guy Sitting in State.

Matheson Float with Trophies.

QUESTION JAMAICA STRAIGHTAWAY COURSE.

According to a story printed in the New York *Globe*, Tuesday, the Hillside avenue course at Jamaica, L. I., was 235 feet short for the mile, and 270 feet short for the two-mile stretch. According to the *Globe* story, John Middletown, civil engineer of Brooklyn, in the presence of C. R. Hendricks, Ralph De Palma, and W. J. Morgan, measured the course and discovered the discrepancy. According to members of the committee in charge of last week's races, this measuring must have been started from the wrong mark. On this point they are very positive.

GOVERNOR HUGHES WILL GRANT A HEARING.

ALBANY, N. Y., May 5.—Governor Hughes this noon announced that he had decided to grant a hearing on the Allds-Hamm Motor Vehicle bill, Tuesday next, at 4 P. M.

The National Highways Prospective Society, practically a New York City proposition, was energetic in asking for the hearing.

A meeting of directors of the New York State Automobile Association has been called at Albany to-morrow (Friday). Automobilists will use their united influence in convincing the Governor that the proposed law exactly meets present needs.

AMERICAN LOCOMOTIVE JOINS A. L. A. M.

Announcement was made Wednesday of the admission of the American Locomotive Company to membership in the Association of Licensed Automobile Manufacturers. Included in the publicity matter from the A. L. A. M. is the following:

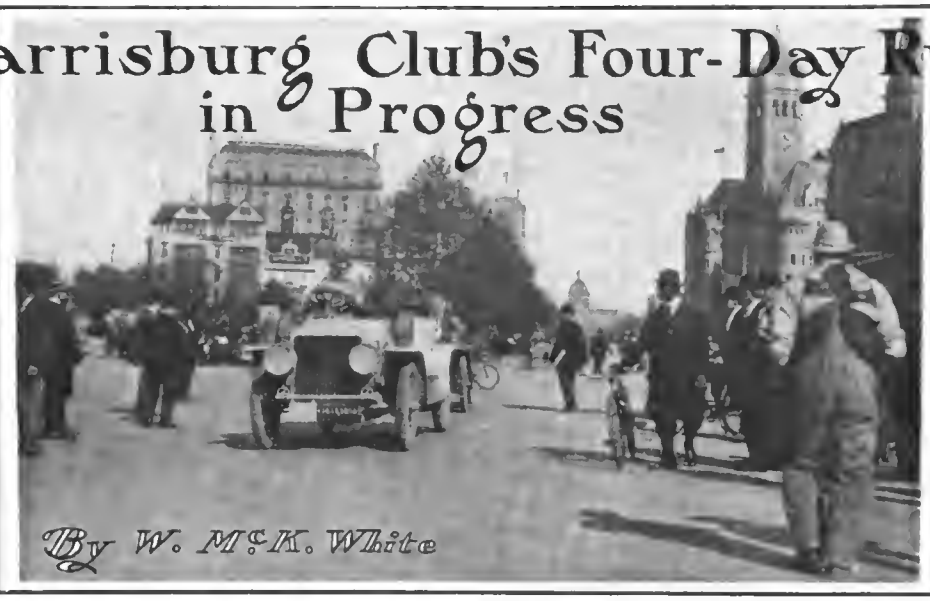
"That such an important company should acquire license under the Selden patent at this time is not only a matter of considerable interest, but perhaps very significant, inasmuch as the trial of test cases of the Selden patent, which is claimed to cover all gasoline automobiles now being commercially made, is about to be had in the United States Federal Court; the cases being on this month's calendar."

FLINT COMPANY BRINGS LICENSE SUIT.

Against several members of the Association of Licensed Automobile Manufacturers, the Flint Automobile Company, of Flint, Mich., Tuesday, began in the United States Circuit Court, Brooklyn, a suit for $75,000 damages, alleging that it was prevented from conducting its operations because it refused to pay royalty on the Selden patent. Of course, many of the allegations by the plaintiff are repetitions of items in the litigation long pending.

Beginning of the Abandoned Effort for the April 29 Military Demonstration Which the Rain Peremptorily Ended.

Harrisburg Club's Four-Day Run in Progress



Arrival of the Endurance Contestants at the Nation's Capital, Coming Up Pennsylvania Avenue.

HARRISBURG, Pa., May 6.—Historic and picturesque Pennsylvania and Maryland are this week the scene of a four-day reliability contest—the third of the Motor Club of Harrisburg. Valleys, hills and mountains are on the route of the 694 miles, with all possible road surface conditions, and coupled with rigorous rules and other requirements to thoroughly test those cars which are essaying the trip. The start was made Monday morning; distance, 153 miles, to the national capital, Washington, and interspersed with four checking stations. A return to Harrisburg occupied the second day, with four controls, and the route was entirely different from the outbound run, a length of 170 miles. A still longer route was that for Wednesday, following the Susquehanna Valley and then bearing eastward to Wilkes-Barre, 180 miles, for the night. The Pocono Mountains are being crossed to-day, in the final lap, the longest of them all—189 miles—back to Harrisburg.

As a contest, this one is thorough and exacting, the roads being the prime testers, and as the result of these and in connection with them come the rules and time schedule. Other runs have had more entries, and it was expectd that the list would be larger, but the strenuous nature of the event probably discouraged participants. Fourteen cars started, and their drivers include those noted for success in affairs of this kind.

There are four trophies, one for each class, that for the large touring cars having been donated by Governor Edwin S. Stuart, who is an enthusiastic automobilist. That for the smaller ones was given by the Harrisburg Board of Trade, and of the two in the runabout classes one is given by the Washington automobilists, known as the National Capital cup, and the other is the Harrisburg *Patriot* cup.

Chairman Beecroft, of the technical committee, marshalled his forces early on Sunday afternoon, J. C. Kerrison, of Boston, and Mr. Wright, of this city, acting as his assistants, and the work of examining and sealing the cars commenced. Some few notations were made at the instance of the drivers as to parts or accessories on their cars, which, while doing the required work satisfactorily, would not class as perfect. Play in steering wheels was noted in degrees, and then the seals attached to coils, battery boxes, floor boards, hoods, and other parts of the cars through which work might be done. It afterwords developed that the seals were of little use, inasmuch as they were allowed to be broken at noon for oiling, or at any control, and during the remainder of the days the parts were unsealed. The committee was able to complete the examination by evening, and at a meeting held in the clubrooms the details of the event were explained to drivers, mechanics, observers, and mere tourists by Referee Johnston.

Regulations used in previous runs of the club had proven so satisfactory that with few alterations they were adopted for this year. Briefly, they included the following: A definite time schedule, with numerous intermediate checking stations; observers to report any work done for which there was a penalty, except that of oiling at stated times and places; a thorough technical examination. The remaining rules hinged mainly on these three. As an average the schedule called for between 18 and 20 miles per hour, with time lost in repairing tire troubles not taken out, but for unavoidable delays time was allowed. Penalties were inflicted for motor stops, except when filling with gasoline, or at the noon control, and if the motor was stopped momentarily, as by stalling, an easy start set aside any reason for penalty. For making adjustments two points per man per minute was inflicted, with five for broken seals. Herewith is the list of all cars, contesting and official, participating in the run:

CONTESTANTS.

CLASS A—TOURING CARS CATALOGUED AT $2,250 AND OVER.

No.	Car.	H.P.	Cyl. Bore.	Piston Stroke.	Model.	Cyl.	Driver.
1.	Oldsmobile	60	4 3-4	4 3-4	Z	6	T. W. Berger.

Maxwell	24-30	Press Car	A. Redmond.

THERE WERE PENALTIES ON THE FIRST DAY.

WASHINGTON, D. C., May 3.—As soon as the contestants were started from the public square in Harrisburg their troubles began, for there was a short run over the Susquehanna river bridges, a drop into mud, more mud, and deep holes. Penalties were bound to occur after a run of that character, and that there were as few as were recorded is evidence of sturdiness.

Six absolutely clean scores were placed on the official record in place of fourteen perfect ones when the morning began. Of the remaining eight, however, deliberation may change the marks against the cars, inasmuch as four have been announced as incomplete, such as those that were blocked, or took wrong roads, etc., while one car was withdrawn, and three penalized definitely. Walter C. White was one of those to suffer penalty, seven points being his share, five of which was for breaking the seal of his hood to examine a leaking water union and two points for the minute or less needed in which to tighten it. The Maxwell roadster turned a spring shackle, not a matter for concern in ordinary touring, but in a contest an occurrence for which two points is the price. The Thomas Light Six received 17 points, five for breaking the seal of the hood and the remainder for oiling when not in a control and for fixing a rod which is between the front goosenecks of the frame, broken en route. The car withdrawn is the small White touring car, which had a key on the rear axle shear off. This necessitated the replacement of the part, and some work, but the car arrived this evening, and will continue as a non-contestant.

Two hours and a half was the time allowed for the first control, that between Harrisburg and historic Gettysburg, a distance of 37.7 miles, made up of roads which could hardly be much worse and still be passable. When the tourists were not being precipitated into some puddle or hole they were standing up in the cars while passing over waterbreaks, so that the entire ride was a rough one.

The second lap of the day, from Gettysburg to the famous old town of Hagerstown, was 34.3 miles long, and the time called for was two hours, so that the average of 17 miles per hour gives an indication that allowance was being made for tedious work. The roads were not muddy as the autos approached the Mason and Dixon line; in fact, they were so dry that the dust was thick, but very rough, with a hard surface. To Frederick—always associated with Barbara Freitchie—from Hagerstown was 25.9 miles, and the schedule called for a time of 1 hour 25 minutes; then there was a stretch of 23.6, with an hour and a quarter given; and finally Washington, 31.7 miles, in 1 hour 40 minutes.

The National Capital road laws received a great deal of bitter and apparently well-deserved criticism from the members of the party, for not only are the speed limits extra low, but the drivers of wagons have no conception of the meaning of "keep to the right," nor do the people seem to care whether they are walking on the street or the sidewalks. Three of the party were arrested for "speeding" at fourteen miles an hour.

SIX CLEAN SURVIVORS ON SECOND DAY.

HARRISBURG, PA., May 4.—The run was planned with the idea that Harrisburg should see more of the contestants than is usual, and so the city not only has start and finish, but also a night control en route. From Washington, D. C., to-day the cars returned, but by a different route. Baltimore, York and Lancaster were prominent points in the itinerary, and the roads were generally rough, with the exception of the stretches from the "City of Magnificent Distances" to Baltimore.

Roughness and dustiness had little effect on the contestants, for of the three penalties inflicted only one involved a car which had a perfect score previously. Another minus mark went to a car with a low record against it. The Rambler, Middleby and Maxwell roadster were the sufferers. In the score announced at Washington there were four given as incomplete: Pullman roadster, driven by Hardisty, was set at 9 points for lateness; another Pullman, a small runabout, driven by Goodman, received 19 points for the same reason; the Rambler, which is slated at 735—241 for lateness and 494 for work done; and the Middleby, which was later set perfect.

The run of to-day has affected two of these: the Rambler, which is again given as incomplete, for a few adjustments were made to-day that may lead its driver to decide upon withdrawal rather than to carry a heavy handicap of points. The Middleby had not arrived at a late hour, and so is put down as incomplete again. The Maxwell roadster had an exciting experience, and for work done there is a penalty of 56 points, while its time record had not been calculated completely.

As a result of two days of touring there are three clean scores in class A, out of six starters; two clean in class B, out of three; one clean in class C, out of two at the beginning, and there is none clean in the small runabout class.

Oldsmobile, Franklin; Pullman touring car, driven by Morton; Pullman touring, driven by Hardisty; Maxwell touring car, driven by Goldthwaite, and the Peerless roadster are perfect.

With no roadside troubles of moment, and just as little tire changes, there were two incidents happening en route to attract attention, aside from that of the beautiful scenery and the road conditions. One occurred to a Maxwell roadster, driven by J. E. Sellers, which met a man with two horses near York. One was being led and the other loose, and at just the critical moment the latter jumped across the road and was hit by the car. Sellers set his brakes, skidding the rear wheels, and from hitting the heavy animal and the road conditions the car turned upside down. The driver and observer were thrown free, the latter being stunned and the horse's left front leg was broken. The motor continued to run bottom side up, and when the car was righted, with the assistance of passengers in official cars, there was little damage apparent except bent fenders. The car proceeded, reaching this city somewhat late.

The Stoddard-Dayton touring car, which was carrying the checkers ahead of the run, scared a horse in Westminster, causing the animal to break a shaft and the top of the buggy to which it was attached. The driver of the car was held to await action for damages, as is usually the case happening to autoists whether they are to blame or not, and the checkers were taken on by Referee R. H. Johnston's six-cylinder Thomas.

The "Capital City" was left at 7 o'clock, with the day a beautiful one, and the ride to the outskirts of Baltimore was generally magnificent, as hard and smooth as a floor, with the few rough intervals being put into shape, so that the route will be one of the best examples of excellent road building in existence.

The Automobile Club of Maryland supplied box lunches and in other ways made the short stay extremely pleasant.

Cordial enthusiasm was shown between Baltimore and Harrisburg, many automobiles being parked along the country roadside, while other people drove to the route in carriages, and work was generally suspended in smaller towns. Hanover and other larger places turned out in force, while at Steelton the police force kept the paved streets clear while many of the drivers took advantage of a sign which read "Speed Limit, 95 Miles per Hour."

Herewith is the score at the second day's conclusion:

COMBINED SCORE FOR FIRST AND SECOND DAYS.

CLASS A.

No.	Car.	Time.	Work.	Seals.	Oil.	Gas.	Water.	Total.
1.	Oldsmobile	0	0	0	0	0	0	0
2.	Pullman	0	0	0	0	0	0	0
8.	Maxwell	0	0	0	0	0	0	0
12.	Franklin	0	0	0	0	0	0	0
10.	White	0	2	5	0	0	0	7
11.	Thomas	0	12	5	0	0	0	17
*6.	Rambler	241	494	0	0	0	0	735

*Second day penalties not yet computed.

CLASS B.

No.	Car.	Time.	Work.	Seals.	Oil.	Gas.	Water.	Total.
4.	Pullman	0	0	0	0	0	0	0
9.	White—Withdrawn, continue as non-contestant.							

CLASS C.

No.	Car.	Time.	Work.	Seals.	Oil.	Gas.	Water.	Total.
15.	Peerless	0	0	0	0	0	0	0
3.	Pullman	9	0	0	0	0	0	9

CLASS D.

No.	Car.	Time.	Work.	Seals.	Oil.	Gas.	Water.	Total.
7.	Middleby	0	0	0	0	0	0	0
5.	Pullman	19	0	0	0	0	0	19
16.	Maxwell*	0	58	0	0	0	0	58

*Second day penalties not yet computed.

sturdiness of the cars.

WEDNESDAY REDUCES PERFECT SCORES.

SUNBURY, PA., May 5.—The first leg of to-day's course, 58 miles, reduced the number of perfect scores to three: Franklin, Peerless, Oldsmobile. All others are late. Roads are in terrible condition, as result of high water, and tire troubles are numerous.

"Andy" Auble, Oldsmobiler," wins Pittsburgh Endurance Race

PITTSBURGH, May 3.—For just one-half of the past week the automobilists of western Pennsylvania occupied the center of the stage. The "doings" consisted of an extremely well-fought "mud plug," officially known as an endurance run. This was planned by the *Chronicle-Telegraph* and the *Gazette-Times*. The dates first selected for the run were later changed in the hope that the muddy country roads would be in better condition. This was a delusion, for with the heavy rains which lasted nearly all the week conditions on many of the roads traveled could not have been worse. The extended preparations for the run, however, served to create tremendous enthusiasm all along the line, and there was not a town or village on the route which had not been fully advised of the event and which did not in some way show its appreciation of the honor.

The route lay over hilly, rough, and muddy cross-country roads, through the unsettled portions of eight counties surrounding Pittsburgh, beginning in a terrific rain and hail storm, and ending on the third day in a snowstorm, that was blinding in its ferocity.

Thirty-seven cars were entered, twenty-four started, and eleven finished. After the technical examination, not a single perfect score remained.

Pos.	Make.	Class.	Driver.	Time.	Penalties Rprs. and Adjustm't	Total.
1	Oldsmobile	B	A. Auble	18	17.0	35.0
2	Knox	B	W. J. Murphy	63	.9	63.9
3	Premier	B	Ray F. McNamara.	65	1.5	66.5
4	Oldsmobile	B	F. G. Folberth.....	70	1.2	71.2
5	Chalmers-Detroit.	B	C. B. Lorimer.....	70	13.0	83.0
6	Packard	A	George F. Titlow..	86	3.2	89.2
7	Peerless	A	O. E. Vestal.....	87	6.6	93.6
8	Franklin	B	C. S. Carris.....	102	.0	102.0
9	Corbin	B	W. C. Urling.....	257	25.9	282.9
10	Maxwell Roadster	D	C. E. Goldthwaite.	302	17.9	319.9
11	Maxwell Baby....	E	E. G. Gager.....1013		2.6	1015.6

The run was divided into three days, starting from and finishing at the Hotel Schenley. A different route, laid out in a different direction, was pursued each day, with the cars operating under time limits. This meant penalties each day, in addition to which the referee and judges took the cars in hand after the close and went over them in search of replacements or repairs. The result of their search, added to the previous accumulations of trouble, gave the final standing. When this was announced joy reigned supreme in the Oldsmobile camp. Not only did "Andy" Auble, in Olds No. 11, win hands down, but Folberth, driving No. 12, edged in fourth. As this was the only make to have two cars finish, the adherents of it made "some" noise.

Some famous drivers were entered in the contest. C. E. Goldthwaite, who was in the Maxwell 10,000-mile non-stop contest, also drove a Maxwell in this run. "Perfect Score" Franklin Carris had to doff his plumes, for he was penalized 102 points. Earl Kiser, of racing fame, found it rather monotonous eating mud, but stuck to the game pluckily. The mighty Hans Wagner, without whom the Pittsburgh baseball team would be a sorry affair, entered his car for the run with explicit instructions to the driver that it should not be marred. It was ready for the paint shop at the end of the first day.

Assisting Referee Ferguson at the start were Drs. W. C. Cook and W. R. Stephens, the judges, and Chief Observer I. F. Bailey. Pilot E. W. Cole left at 5 o'clock in the morning in a Velie car provided by the Keystone Automobile Company. W. N. Murray, president of the Standard Automobile Company, in a Packard, handled the official car of the route.

From a social standpoint the endurance run was a great success and the newspaper management was warmly commended on all sides for the cordial way in which they helped along the making of acquaintances and the firmer bonding of old ties among the automobilists of western Pennsylvania. The dinner given by the newspapers to the contestants and their friends Tuesday evening was followed by a banquet to the contestants Friday evening. At the latter several of the city officials were present and experiences were "swapped" for several hours, over a choice menu that was evidently relished.

No serious accidents occurred on the run. Tire troubles and upsets, the latter due generally to ignorance of the routes, were the worst feature reported. On the second day out L. R. Lorimer, driver of a Chalmers-Detroit, demonstrated that "necessity is the mother of invention." When his tire gave out he bought a bushel of oats from a farmer, crammed the tire full, poured in a pail of water, laced it up and on the swollen grain rode 14 miles before he had to take to the bare rim again. At Washington, a Knox car, driven by W. J. Murphy, was struck by a street car and badly injured, but stayed in the contest. The Corbin, with unlucky "13" tied to it, had all kinds of trouble near Uniontown, but managed to get into running condition again. A country constable near New Castle was bent on showing his authority and caused the arrest of two drivers for speeding. They were promptly released after giving bail, and when the circumstances were explained to the higher authorities the constable's efforts went for naught.

WHY AUTO INDUSTRY DOES NOT RESEMBLE PREDECESSOR

By CHARLES CLIFTON, President A. L. A. M.

IT is frequently remarked by those associated with the automobile business, as well as by comparatively unthinking laymen, that the automobile business will follow in the footsteps of the bicycle business. This statement is generally accepted as a sage prophecy, the unthinking prophet assuming to himself the virtue of wisdom. But the history of the rise and fall of the bicycle business will not be repeated in the automobile industry.

As one of those associated in the bicycle business, and conversant with the history of the transition from the bicycle to the automobile as a means of transportation, I have made a careful study of the problem and arrived at certain conclusions. The only common element of the two industries, aside from each representing a method of locomotion, arises from the fact that the early development of the automobile in a commercial way occurred at a time when the bicycle business, as a large industry turning out a popular product, had commeneed to wane, its doom being plainly written. The situation was such that a large amount of capital, energy, producing and selling brains was rendered comparatively idle, and consequently those forces were logically attracted to the automobile business, which had alluring prospects and called apparently for the same essential elements. Thus several of the earlier bicycle makers were pioneers in automobile development; and many mechanics, theretofore engaged in the bicycle industry, being skillful in detail, have in minor capacities aided automobile development in either invention or shop practice. Naturally the automobile attracted to it a selling force, including bicycle dealers. The latter brought into the new industry a rich experience, which unfortunately too few of them realized to the fullest extent, particularly as to the proper function of adversity. Many of them transplanted lax business methods, extravagances and other undesirable phases. They were fond of referring to the new industry as a "game," as to a sporting event, or a hand at poker. Early the old selling methods began to show themselves in instalment sales and questionable methods of attracting and holding business. But in the new industry these elements were, naturally, short-lived.

Many people are prone to say that overproduction killed the old bicycle business. But if they would reflect on the decreased number of wheels in use, I think the answer is obvious. The bicycle was comparatively short-lived on account, in my judgment, of its own limitations. In its day it was regarded as a wonder of convenience in the solving of the essential transportation problem of how best to accomplish a given distance on common roads. It also had the fascination of a healthy outdoor exercise. But it always involved more or less hard work, more or less of the discomforts of the road, and always the limitation of the rider. It, moreover, did not admit of diserimination whereby the love of display, the superiority purchaseable by money, or the essential comfort of the individual could be expressed.

As the result of the expenditure of an enormous amount of money and work by the American pioneer makers, nearly all of whom are members of the Association of Licensed Automobile Manufacturers, the automobile as a means of transportation has become a part of our national life. It is rapidly supplanting the older forms of individual mechanical locomotion; and will endure because it not only supplants, but far surpasses, anything of its kind we have ever known. It will not decline, but grow, because ever since civilized man has been obliged to move from place to place, for pleasure, convenience, or profit, he has had to use the horse, the mule, or the camel, with much limitation in point of distance and speed, and at all times with uncertainty. The new means of common road transportation is untiring and limitless. It has proven itself to be what the people want. It has individuality in form, and variety, and is built to suit any purse.

In the minds of thoughtful people, of those who think conservatively, the automobile as a means of eonveyance has but one menace to its supremacy, and that is navigation of the air, which, if successfully accomplished as to safety and economy, will undoubtedly make the automobile in a way old-fashioned. But even when that day arrives, there will still be numberless people who prefer to be on the ground.

HOW MUCH DOES AUTO WEAR OUT ROADS?

BY invitation of the executive committee of the American Automobile Association, Logan Waller Page, director of the U. S. Office of Public Boards, in the Department of Agriculture, was present at the meeting Tuesday at national headquarters, 437 Fifth avenue, New York City. The result was a decision to hold, probably in June, a series of severe tests to determine: First, just what damage the automobile does to the road surface; and, second, what will be the best measures in road building to prevent the breaking up of road surfaces from constant automobile traffic. Under the auspices of Director Page tentative tests of this character recently took place on a special road near Washington, controlled by the War Department.

"The object of the coming tests," said Mr. Page, "is to get at facts. So many theories have been advanced regarding the causes of road damage by motor cars and the best preparations to preserve these roads that it is high time to ascertain the real truth of the situation. At these tests all of the State Highway Commissions will be invited in addition to the County and local Highway Commissioners where the tests are held. An exhaustive report will then he made, which will be sent to all of the legislative bodies throughout the country and others interested in the good roads question."

The executive committee authorized the tests and referred the matter to the Good Roads Board, of which George C. Diehl, of Buffalo, is chairman. If satisfactory roads can be found, the test will be held in the vicinity of New York.

In the tentative specifications drawn up, it was agreed that there should be two stretches of macadam road, one about three miles long, practically level and with as few curves as possible, while the other should be a road of a similar character about one mile long with a grade of about 6 per cent. Twelve automobiles will be used, four being light high-speed cars, preferably stripped for racing, four touring cars, and four heavy limousine cars.

In the opinion of the committee the trials should be made as follows: On a straight, level course, two miles from the start 400 yards should be measured off and an apparatus arranged for measuring the speed. At the beginning of these 400 yards four high-speed cameras will be stationed to take right angle pictures. A second station will be placed 100 feet farther on, and a third station at 200 feet. The cars will go over this 400-yard section at speeds of 5, 10, 15, 20, 25, and 30 miles per hour, and in regular increments of five miles increased until the maximum speeds are obtained. On the 6 per cent. grade the cars will go up the grade at maximum speeds and down a grade at approximately the same speed, coasting.

In addition, it is also proposed to hold a test over a road with the surface being bound by a dustless preparation.

At the executive committee meeting over which President Speare, of Boston, presided, there were present: Samuel A. Miles, N. A. A. M.; E. P. Chalfant, A. L. A. M.; Alfred Reeves, A. M. C. M. A.; W. E. Metzger, L. J. Powers, Jr., and Secretary F. H. Elliott.

The committee voted to recommend to A. A. A. clubs the week beginning June 1 for orphans' day outings.

The Hermitage Automobile Club, Nashville, Tenn., and the Tampa Automobile Club, Tampa, Fla., secured membership.

Automobile Gasoline and Other Available Fuel

Part IV

By Thos. J. Fay

ORDINARILY, in view of the proneness of automobile gasoline to enter the cylinders in liquid form, the need of quite a length of tubing in the make-up of the carbureter manifold would seem to be an actual necessity. Since the gasoline enters the intake as a liquid, and since the amount of heat available in the air that enters, is not enough to assure vaporization, the greater the length of the manifold, within certain limits, the greater will be the chance of vaporizing the gasoline, since some heat will pass through the walls of the manifold, especially after the motor heats up, because some of the heat will be communicated to the entrained liquid in the mixture, while in the manifold. Then there is the problem involving the delivery of an equal weight of mixture to each of the cylinders; if the mixture is not a homogeneous gas there is small chance of delivering an equal weight of the same to the respective cylinders for the reason that the question of condensation, together with the mechanical separating out of the unvaporized gasoline, in a manner not likely to be uniform in the several cylinders.

In a measure, then, this question of a uniform weight of mixture to the respective cylinders cannot be brought about unless the mixture is free from gasoline in the liquid state. All that is

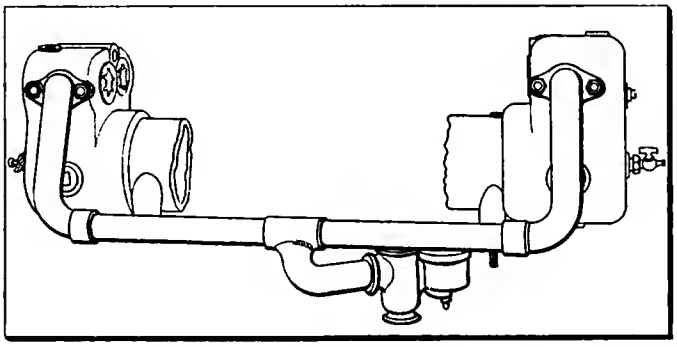

Fig. 11.—Good practice in manifolds for double-opposed motors, showing connections on one side of motor for both cylinders.

wanted in the cylinders of a motor is a fixed amount of homogeneous mixture, the same for each of the cylinders, under like compression and fired at a common angle of advance. On the face of it the mixture must be made, and up to the standard, before it will be profitable to talk about its used and if it is not uniform, equality of distribution will be quite out of the question, so that on the whole the principle problem lies in the process of carburetion.

There Is a Story Connected with the Intake Manifolds.—If the mixture from the carbureter is in the right proportion, and provided entrained gasoline is done away with, it becomes a question of the right distribution of the same to the respective cylinders. In a single-cylinder motor it would seem as if the problem would present itself in the most simple form, and such is the case provided the manifold is of adequate area, and if the hydraulic grade is toward the carbureter. That the manifold should be of some length seems to be a settled requirement, but there is a limit which must not be exceeded if it is true that motors must crank without much, if any, priming, and if the gasoline in the fuel is to be enough and uniformly provided.

In many cases, and in the past in some schools of design, it was assumed that the carbureter should be as near the cylinder as possible, and when the same was placed at a distance it was regarded as bad practice. The area of the manifold was generally increased with the hope that losses would be minimized, but the results did not always show that the practice was a good one, and in the long run it was considered that the area should relate to the valve area, or better yet, to the piston displacement of the motor. Why this is true was not well stated, but experience has taught that the mixture is better when the conditions

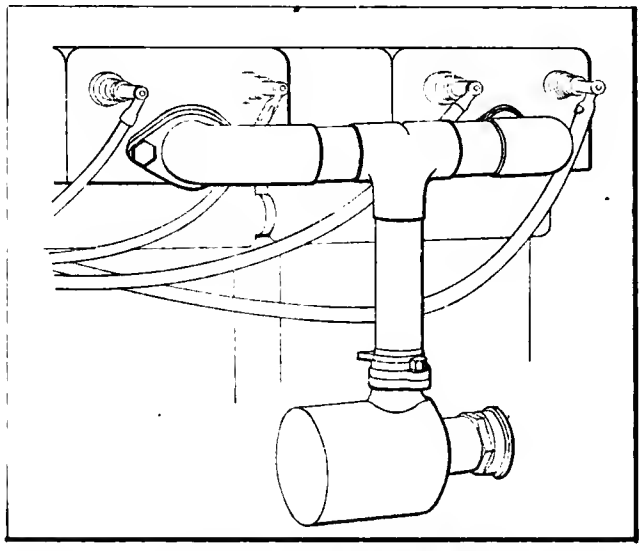

Fig. 12—Make-up manifold showing right-angle turns, involving a raiser and two branches.

that obtain take into account the lack of imperfect carbureter performance. In some cases it was the practice to consider that the intake manifold was really a part of the carbureter, in that vaporization must take place therein, if this important part of the performance does transpire outside of the motor cylinders, which is a moot question, in these days, due to the properties of automobile gasoline, considering the lack of volatility, as indicated by the boiling point of the same, which has been shown to be above the boiling point of water, for the most part.

That there is a happy medium, which depends upon the carbureter used, and the characteristics of the motor in each case is the one conclusion that would seem to stand the light of systematic investigation, and that the rules should not be applied too generally is also true. If, in a single-cylinder motor, the area of the manifold is one-quarter of the area of the piston, and if the length is four times the stroke of the same, it is then that the mixture will be allowed to rest in the manifold

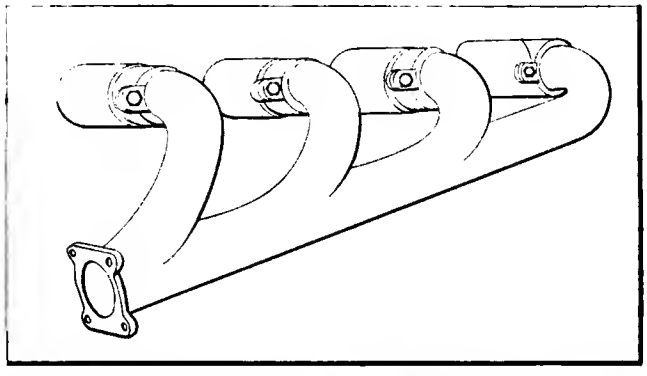

Fig. 13—Manifold so contrived to assure equal distances for all cylinder-ports from depression chamber in carbureter.

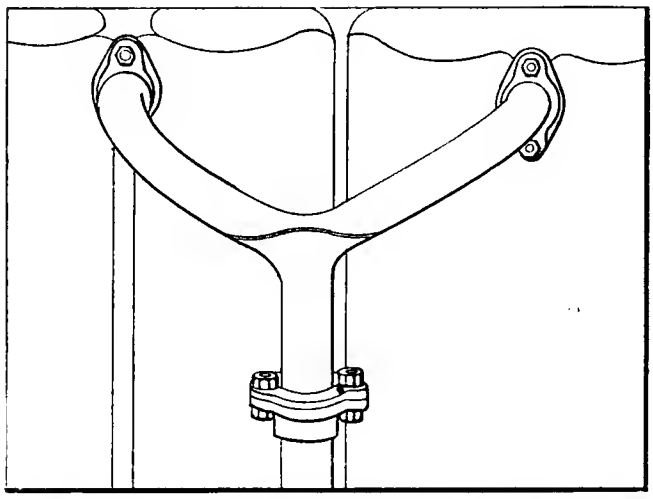

Fig. 14—Manifold of the Y class, with a long, slender raiser and easy bends at all points.

for a time equal to one complete cycle in a four-cycle motor. If the motor delivers maximum power at, say, 1,600 revolutions per minute, the mixture will be allowed to rest in the manifold for a period of time equal to:

$$t = \frac{S}{60 \times c} = \frac{1{,}600}{60 \times 4} = 6.6$$

when,

t = ratio of time that the mixture will lie in the manifold, considering a single-cylinder motor,

S = angular velocity of the crankshaft in revolutions per minute,

c = cyclic period of the motor.

NOTE: During one-quarter of this time the mixture will be enroute to the cylinder, during which period the mixture will not actually lie still in the manifold.

In a single-cylinder motor it is not difficult to regulate the volume of the intake manifold in relation to the piston displacement, but when the number of cylinders are increased the problem becomes more complex. If the relation of the manifold to the piston displacement is not maintained, the torque of the motor may fall off as the speed increases, which is what happens, but not at the same point in the piston speed in all makes of motors. Fig. 11 is illustrative of fairly good practice in two-cylinder motor work, in which it will be observed that the intake is long and slender and the connections in the cylinders come in such a way that the distribution to the respective cylinders is about equal. That the distribution should be so is one of the points to be made, and it certainly is worth something to be able to readily remove the manifold if, in service, it becomes desirable to do so. In this example the hydraulic grade is greater than the net requirement, due to the desire to clear other parts of the motor; this is not necessarily a fault, and it may be that

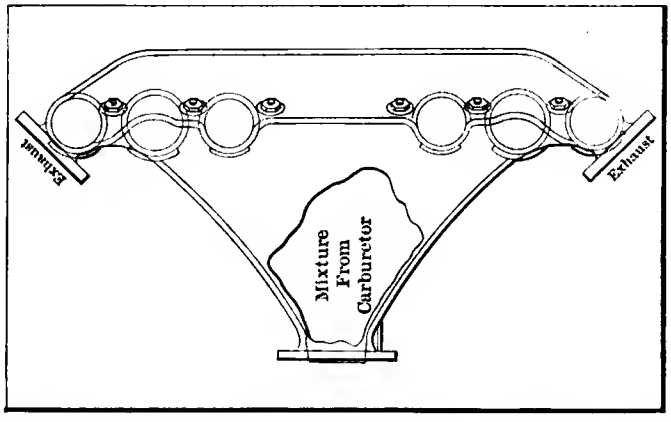

Fig. 15—Manifold of a box-like character, with provision to utilize exhaust heat.

it is an advantage to have the mixture travel through a vertical distance, with the hope that some of the entrained liquid will be weeded out by the gravitational process.

As the number of cylinders are increased, the practical applications become more diversified and there is one more point to be made in that the several methods in vogue seem to work, each in a way to satisfy the needs of the occasion, hence the only question is: Can the trend be picked out of the flock, and has it an upward tendency?

Some Methods in Vogue with Four Cylinders.—However light air may be, even so, it weighs something, and inertia has to be taken into account. When the stream of gas is in motion its tendency is to remain in motion, and to change direction, without suffering a detriment, requires that the conditions be right. The first principle of good designing has for its basis the form under which no change in direction will be required, but if it is the purpose to abandon this principle, then the wise plan will lie

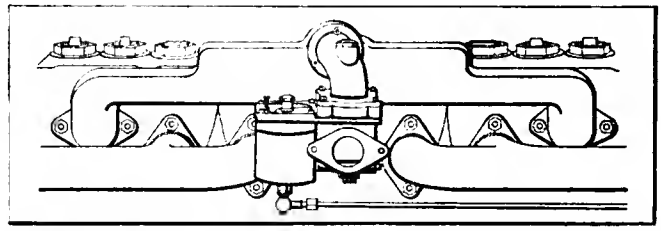

Fig. 16—Enlarged T-shaped manifold, with rather abrupt reductions in the lateral portions.

in having equal and opposite forces, so that the ills of the scheme will not be transfered to the motor.

Fig. 12 offers a plan in which the manifold for the intake is made up, and owing to the form of construction, the bends are right angles. This manifold consists of a raiser and two

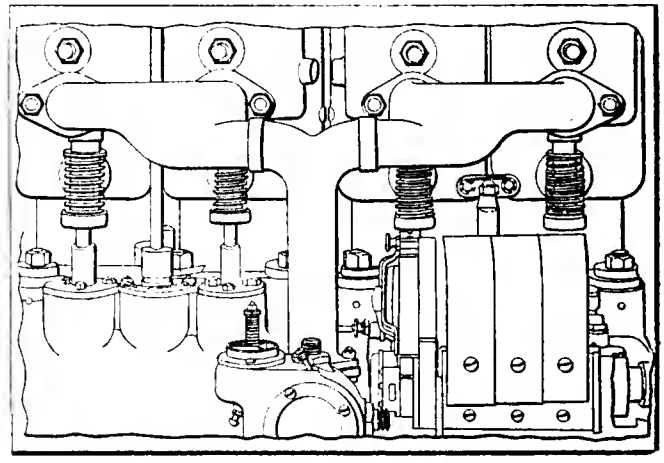

Fig. 17—Another manifold, differing in detail from that shown in Fig. 16, with easier bends from the raiser.

branches, each of which leads to twin cylinders. Considering the usual order of firing a four-cylinder motor, the gas will be sucked into each branch alternately, and that inertia will rob the mixture of its accustomed density is believed. The two arms of the manifold are horizontal and the result is that the hydraulic grade, that retards migration in the direction of the cylinders, is not taken advantage of.

As a refreshing diversion Fig. 13 is offered to utilize the benefits of a hydraulic grade, and tap the mixture off to the respective cylinders without changing its direction and to the extent possible, have all the cylinders the same distance from the carbureter. Considering "individual" cylinders, this manifold lends itself extremely well, and it will also look good when the casting is well made, which it can be, of aluminum.

If siamesed cylinders are used, the same result will be due to the use of a manifold as shown in Fig. 14, in that the carbureter is well below the valves of the motor and the Y is with long and

slender branches, emanating from the raiser, at a low point. If there is any trouble attached to this scheme, it may be traced to the ports, within the cylinders, rather than to the manifold. Still another plan is disclosed in Fig. 15, involving a Y-shaped manifold with a casting of a box-like character, possessing no dividing walls, excepting those which separate the mixture from the exhaust gases that enter a cored portion of the casting, near the cylinders, high up, for the purpose of aiding in the process of evaporation. In view of the large amount of gas that can be stored in the space afforded it is likely that benefits follow its use, although, in the absence of exhaust heat, the space might be regarded as excessive.

Fig. 16 shows still another way, in which the enlargement is

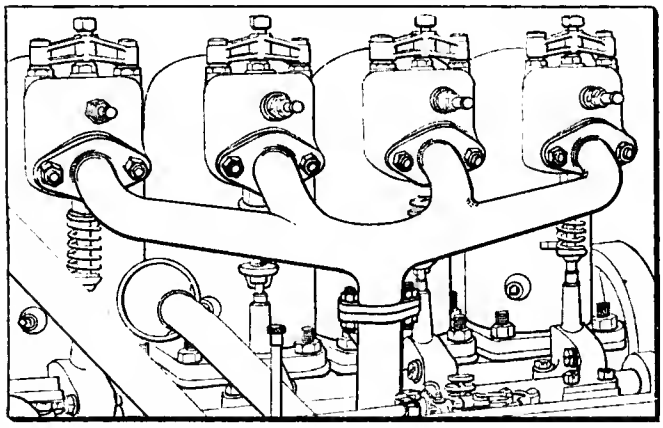

Fig. 18—Manifold for individual cylinders, on a four-cylinder motor, with easy bends, without change in direction of the mixture.

above the raiser although a part of it. This manifold is used on individual, four-cylinder motors, and it should be free from inertia trouble, even so there is danger of other complications in the absence of good carbureter work. This manifold does not offer a large surface for the transfer of heat, which is not a necessity if the carbureter is so devised that the mixture will be in the vapor state, free from entrained liquid. Fig. 17 is of another manifold that belongs to the same school, the only difference being that the enlargement is above the common level of

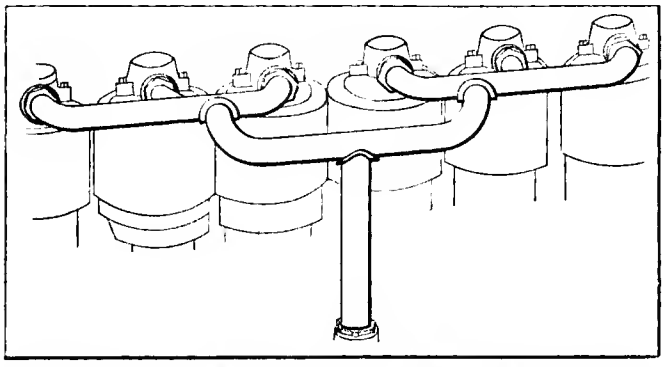

Fig. 19—Manifold for a "six" in which the gas must change direction, thus involving inertia, to some extent.

the portion that branches out to the cylinders. In this case the manifold is devised for six cylinders, and it seems to be a very good plan to get away from the troubles that attend the delivery of mixture to a "six." The hydraulic grade of the branches is not pronounced, but it is not always necessary to have the difference in level so very great. From the simple Y to Fig. 18 is but a step, probably right in that the mixture is not required to change direction, and a neat appearance attends the use of this class of manifolds.

When the plan, as shown in Fig. 18, is applied to a "six" it is not quite so handy, and it may be that it is attended by a certain amount of inefficiency. Fig. 19 is offered as illustrating the point to be made, and as will be observed, if gas inertia amounts to

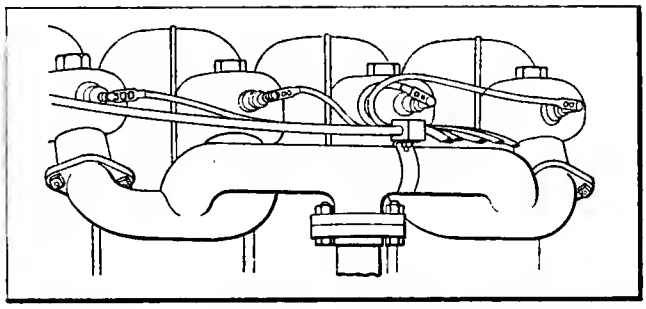

Fig. 20—Manifold, with an attempt to balance inertia forces, with easy bends as well.

anything of practical importance, whatever it does represent will be present in this class of manifold. In this case the gas has to go in the reverse direction to get to cylinders Nos. 3 and 4, while the distance to Nos. 1 and 6 is very great in comparison, although the direction is common to the general trend.

The Method by which Inertia Forces Are Balanced.—In contrast with the plan as shown in Fig. 19 the manifold depicted in Fig. 20 is offered, portraying an effort made to balance the forces due to inertia, in that the laterals leading to the respective cylinders are so connected that the gases will have equal difficulty in all directions. This is probably a very good plan and the reports in practice lend substance to the opinion.

As against this is the scheme depicted in Fig. 21 of a manifold for a "six" in which the pressures of the gas streams are equalized, although it is true that the flow is not in one (common) direction. In this case it is obvious that the designers were alive to the trouble attending the use of the manifold shown in Fig. 19, and it is a reasonable assumption that this way of equalizing is well worth the difference in cost of material. Moreover, the surface offered for the transfer of heat is a maximum, and this is also in the right direction, in the absence of perfect carburetion.

Proper Length of the Intake Manifold.—Considering the presence of carbon in motor cylinders as largely due to unvaporized gasoline, before the fuel enters the cylinders, which carbon is due to the breaking down of the gasoline structure, under the action of heat, in the absence of a right distribution of atmospheric air, rather than to a deficit of oxygen as respects totals, it is reasonable to assume that the manifold, from the carbureter to the cylinders, is, properly speaking, a part of the carbureter, and that the length of the manifold should be such as to do the most good, and that the gasoline, as it is sucked out of the nozzle of the carbureter, should be afforded every opportunity to vaporize. If the manifold is of the required length and if heat is applied to the mixture, through the walls of the manifold, at a constant (desired) temperature, it is then that the manifold becomes a part of the carbureter rather than a connection of convenience, as it is mostly regarded. That the shape of the manifold will influence the situation is rather to be expected. and in conclusion, strange as it may seem, it is better, in all probability, to have the manifolds with a limited area, rather than to employ them with so large an area that the friction factor will be a minimum. It is even possible to consider that benefits will follow a passageway which is tortuous and winding, provided the carburetcd gas travels in one direction only.

(To be continued.)

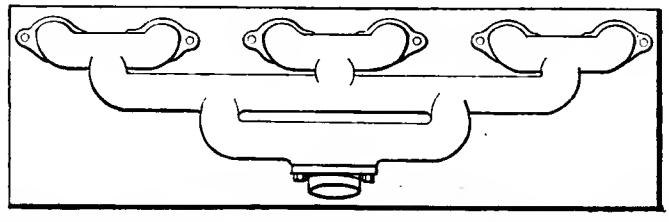

Fig. 21.—Compensating manifold for a "six," wherein the forces due to inertia are but slight and balanced.

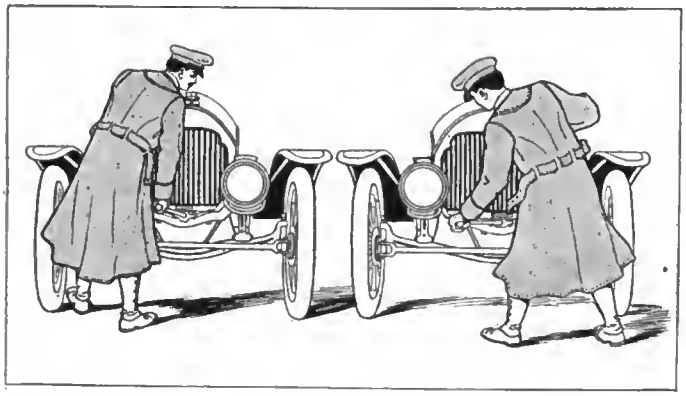
Information for the Man Who Drives

Things to Remember About Starting.—One of the first things that the novice should learn is the proper method of starting. This, too, should be learned in a safe way, for there are methods in daily use which are not safe. Take, for instance, the ordinary way of cranking the motor. Most motors turn clockwise, that is, from left to right. Then, in starting, the



Shows the Improper and Proper Methods of Starting.

ordinary driver, who has just "picked up" driving, grabs the crank with the right hand and pulls on it until the top is reached, then pushes it over the center and the motor either starts or it does not. In the latter case he continues to pull it around. This method, whether right or wrong, may possibly work on a small engine, but wait until this plan is tried upon a large motor.

The driver, to crank in this fashion, must stand at the left and between the center of the car and the wheel or fender. At the top of the stroke, which is also the top of the circle of revolution of the crank, he is in a very awkward position. Worst of all, his arm is extended stiff and a back kick will operate directly against it. In this manner the arm is liable to be broken, or at least badly wrenched. In addition, the awkward position is such that the weight must be concentrated upon the right foot in order to balance. The least tendency toward backfiring is liable to destroy this balance, so that the driver may fall over. The writer has seen men start a car in this fashion, and finding the engine turn over more readily than they had expected and provided for, the very effort of starting was sufficient to upset their balance and they fell over.

With left-hand starting, on the other hand, these three objections are obviated. As the turn of the crank is away from the center of the car, its movement may be counted upon to give the driver more room in which to stand.

Instead of the last and hardest part of the cranking being in the nature of a push with the arms stiffened, with left-hand starting, it is more of a pull with the elbow flexed and therefore free. If the engine back fires it is easier to let go of the spinning crank, because it is exerting a pull on the hand, not a push as before. Then, too, the substitution of a well-balanced position for an awkward one helps to make the action of freeing the crank so as to let it turn freely much easier. The advantages of left-hand starting, then, sum up as: less danger to the operator's arm, easier balance of the body and less work.

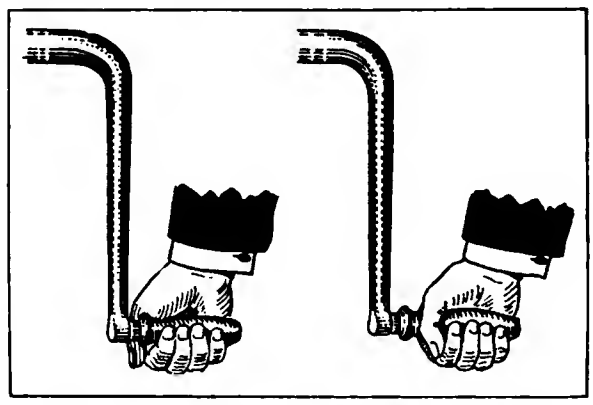
The Amateur's Useful Diary.—One of the first things that the beginner should get is a motorist's diary. This should not take the form of a daily register of everything, making the work of keeping it a hardship. But on the other hand, it should contain a record of the time at which the principal things happened. Thus a form of mileage recorder should be secured and a note made of the mileage at which things occur.

So the diary should contain a record of the distance covered when things occur. It ought to include in this way the punctures, new treads or new tires, charging of batteries, grinding of valves, fresh oil in the transmission or crankcase, examination of various parts, replacements due to wear or accidents and many other little things worth knowing afterward, but forgotten at the time.

By keeping a record of this sort (and a person would be surprised how little time it takes) one can always answer questions directly and exactly. The total life of tires can be found, for instance. The writer knows of one prominent motorist who found out from a diary record of this sort that beyond a certain mileage it did not pay to have tires retreaded, no matter how good they looked. So he fell into the habit of taking the shoes off before that distance and sending them to be retreaded, although they did not then look as if they needed it.

How to Hold the Starting Crank.—In the apparently simple operation of cranking over an automobile engine there are many little points for the novice to consider. Among these the most important are those which make for increased safety. Thus the seemingly elementary action of grasping the crank handle is susceptible of two methods—one, right and safe, the other, not safe, and therefore, not right.

Ordinarily the driver will grasp the handle with a firm grip about as he would grasp a baseball bat; that is, with the fingers wrapped around it in one direction and the thumb around it in the other. Whatever method of cranking is employed this is wrong, for if the motor backfires the position of the thumb prevents letting go, at least quickly enough to be any service.



How to Hold the Crank, Correctly and Incorrectly.

The proper way, as the cut shows, is to take hold with the fingers around the handle, but loosely, never tightly. Then the thumb should not be used at all, but should be folded back alongside of the first finger and out of the way. The whole work is done by the fingers, and if anything happens the backward action of the crank simply opens the closed fingers and no harm is done. This particularly holds true when taken in conjunction with left-hand starting. In that case the latter and dangerous part of the starting action is a pull toward the operator. The arm is in tension, in which the greatest strength can be exerted. So, if the engine backfires, a person just stands still and holds the arm taut, while the backward action of the engine opens the hand and then rotates harmlessly.

Ready Remedies for the Roadside

WHILE the majority of automobiles are reliable and will run for quite a considerable period without the need of repairs or adjustments, still even the best machinery will sometimes need repairing, and the autoist who exercises his ingenuity will not only be able to continue his journey, but will save the cost of a repair bill and sometimes the ignominy of being towed behind a farm wagon. Repairs that call for experts' services and machine work cannot be performed on the road, and would be of no value to a stranded autoist, and are therefore not given here.

Repairing Leaks in Radiators.—Honeycomb radiators are given to "weeping" or leaking at the ends of the cells, and if a radiator plug is not at hand a substitute can be found in passing a long, thin bolt through the defective cell, fitting the bolt at both ends with leather or rubber washers or tire patches, backed with strips of metal, and screwing the nut down until the leak is stopped. If no such bolt is obtainable, a stick can be whittled to take its place and the washers retained by means of copper wire, as in Fig. 1. When a leak occurs inside one of the cells, a square peg cut from soft wood and covered with a piece of handkerchief smeared with white lead can be used as a stopper. In all of these operations only a moderate amount of force should be used, as the tubes are easily buckled. Leaks in gilled-tube radiators can he stopped by applying a rubber patch held in place by tire-tape and wire.

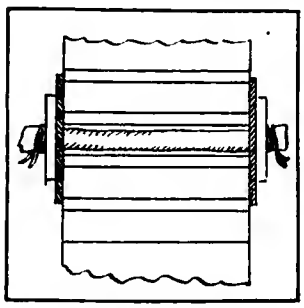


Fig. 1—Section of radiator showing washers held by wires on stick, to stop leak.

Twine Can Be Put to Various Uses.—Speaking of washers, when a lock-washer is missing a fine substitute can be made with twine forming a loop slightly smaller than the outside diameter of the nut and wrapping twine around this loop, forming a "grommet," as the sailors call it. When the nut is screwed down on the grommet it will be held as firmly as if fitted with a nut-lock and will stay tight until the twine rots. Autoists should carry at least some 15 yards of twine in their kit, as it can be put to various other uses about the car, such as reinforcing weak spots in tires, protecting chafed wires and binding together split sections of the steering wheel.

Treating Circulating Pump Leakage.—Leakage of the water circulating pump occurs usually where the cover joins the pump body by means of a ground joint. A gasket of stiff paper dipped in lubricating oil inserted between the cover and the body will remedy this, the gasket being easily formed with the pocket knife. Asbestos cord is better than paper when treated with vaseline and graphite, but few autoists carry it. For leakage around the pump spindle the cord can be used, pushing it in with a piece of strip brass or other soft metal so as to avoid scratching the shaft. If no asbestos cord is at hand one of the strands of a piece of hemp rope treated with tallow will also answer.

When the Gasoline Pipe Gives Trouble.—When the gasoline pipe breaks, a short piece of rubber tubing forced over the broken ends will do for a short time, but as gasoline attacks the rubber too much dependence should not be put on it and the pipe should be brazed at the nearest shop. If the hole is only a small one a piece of soap squeezed in and held in place by a soaped rag and string will serve if gravity feed is used. For pressure tanks a piece of rubber tubing split lengthwise and well soaped will temporarily stop the hole if wired tightly around the pipe, but the pressure must be kept low, otherwise the rubber tubing will be loosened and the leaking commence again. A leak is sometimes hard to locate, but if the pipe is rubbed with lather and blown through, the leak will he shown by bubbles.

Loosening Nuts and Screws.—Refractory nuts can be loosened by heating them with a red-hot piece of iron for a few minutes, when they will come off readily. If a screw cannot be loosened by the screwdriver the latter should be pressed hard against the slot in the head of the screw and turned by a monkey-wrench applied to the flat part of the blade. A tight radiator cap can be moved by winding a large amount of string or cloth tightly around it.

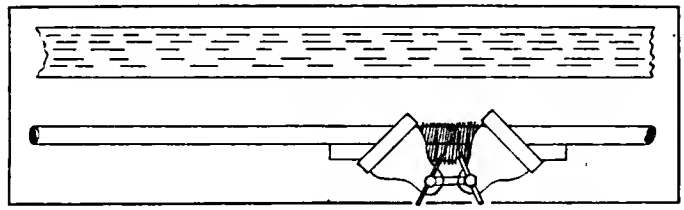

Fig. 2—Repaired drag-link, showing hand vises in place.

Broken Rods and Links Can Temporarily Be Mended.—The repair of a broken link in the steering gear can be effected by placing the broken ends together and fastening a rod or a piece of gaspipe against the link, winding the wire the entire length of the rod. If two hand vises can be obtained they can be attached as shown in Fig. 2. The rod is tied to the joined ends of the link with wire and the hand vises screwed down on both link and rod. Anything but slow running with either of these repairs is out of the question. Any other rod can be similarly repaired provided there is room for the pipe or the vises alongside of it. Wire cable can be substituted for brake rods, but the brake must be kept clear of the drum by some means when not in use.

What to Do When a Chain Breaks.—If a chain breaks and the autoist has no spare links the car can be driven on the other chain after the idle sprocket is secured so that it cannot revolve. An easy way to do this is to pass one end of the chain around the sprocket, fastening the end link to the chain with wire and attaching the other end of the chain to some part of the car, such as a running board bracket. On shaft-driven cars the universal joint pins sometimes work loose and drop out,

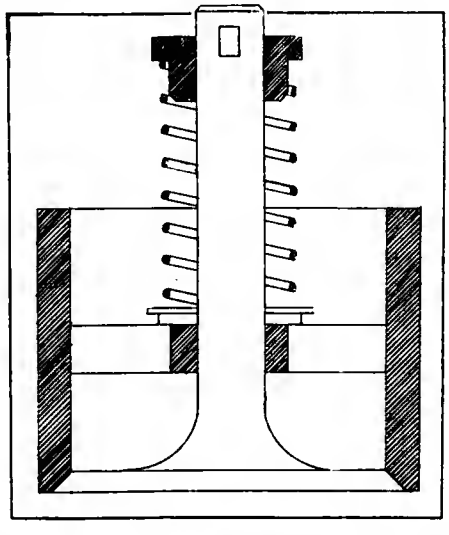

Fig. 3—Valve spring strengthened by inserting metal strips

but a temporary pin can be made from a bundle of wire or a small chisel held in place by wires or twine.

Strengthening Weak Inlet Valve Springs.—Mechanically operated inlet valves have superseded those of the automatic type except for two-cylinder opposed motors fitted in light runabouts and motor buggies. There is a surprisingly large number of these vehicles in service, and as at some time or other the inlet valve springs become weak or break, the following suggestions will not be out of place. If the spring is weak it can be strengthened by inserting strips of brass or the blade of a knife broken off for the purpose between the spring and the spider of the valve cage, as in Fig. 3. In thus strengthening a spring it would be well to test it against another inlet valve spring by placing the ends of the stems together and pressing the cages toward each other as in Fig. 4. The strips of metal can then be put in until the valves both unseat equally, when the springs will be of equal power. If the spring is broken pieces of corset steel can be substituted for it, one end of each steel being notched to straddle the spider arm and being fastened to the collar wedge by wire passed through a hole near the other end as in Fig. 5. Even if the power of the steels is not as great as that of the regular spring the motor will run well enough to bring the car home. A corset-steel-fitted inlet valve was used on a runabout for four days while waiting for a new spring from the factory and was apparently capable of giving some more service when taken out.

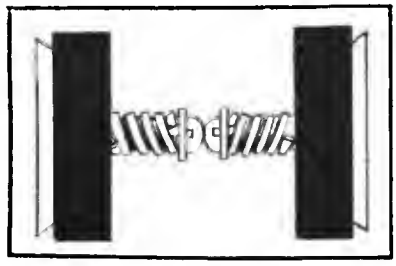

Fig. 4—Method of testing valve springs.

Substitutes for Trembler Blades.—Corset steels can be used as blades for trembler coils, cutting them to the proper length and riveting the platinum button from the broken blade through the hole which is punched by the manufacturer near each end. After making the holes for the retaining screw the blade is complete. A piece of a clock mainspring will also make a good blade.

Remedying Squeaking Springs.—A frequent source of annoyance is the squeaking that indicates that the leaves of the springs require lubrication. The axle is jacked up until the wheels are clear of the ground and the springs quite flat. Then with a chisel or screw driver each leaf should be forced apart gently and a mixture of vaseline, oil and graphite spread between it and the next leaf with a knife or flat steel rule. Where parts are not easily reached by this method they should be squirted with oil. The leaf clips should be removed if necessary to allow of this being done.

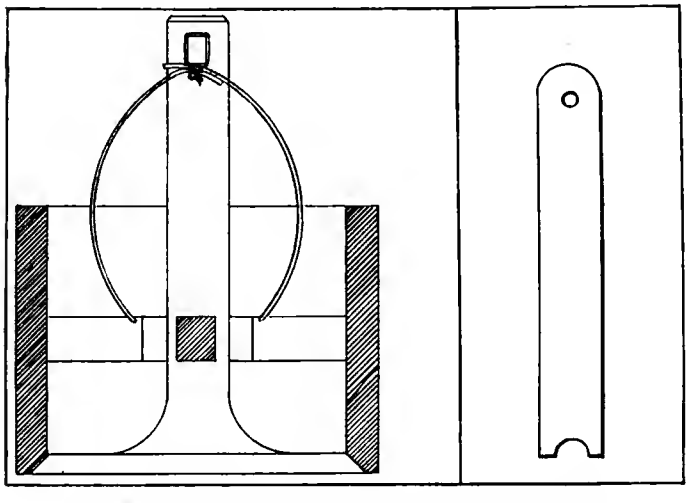

Fig. 5—Corset steels used as impromptu valve springs.

POINTS THAT MAY HELP YOU.

By A. D. HARD, M.D.

There is nothing more exasperating than to get into a small soft place in the road and have the driving wheels spin until the axle rests on the ground and all traction is gone. I used to hunt immediately a farmhouse and get help to haul the car out, but as I do not like to acknowledge dependence on farmers or horses when using an automobile, I have devised the following method of getting out of such predicaments unaided. The material necessary for constructing the device consists of four thick leather straps, 6 feet long and 1½ inches wide, and 26 pieces of hickory wood, 10 inches long, 2 inches wide and ¾ of an inch thick. One-quarter-inch holes were bored at two inches from the ends of the pieces of wood, and the straps riveted to the pieces of wood in such a manner as to make a flexible ladder with leather "rungs," six inches apart from center to center and with 4-inch open spaces between them.

Use of the Strap Ladders.—This gives me two strap ladders, 6 feet long and 10 inches wide. They are snugly rolled up with the strips of wood alternating so as to occupy but little space. When the situation calls for some help to get out of a mud hole I place a trace chain around the rear axle and the frame to prevent the spring expanding, and with the jack under the rear corner of the frame lift the driving wheel up as far as the jack would permit, then unroll the strap ladder on the mud in front of the wheel, with one end under the tread. The other wheel is treated in the same manner, and with low gear the machine will travel over the 6 feet of strap-ladder track with perfect ease. If this does not reach solid ground, I simply repeat the trick until the trouble is passed. This has helped me out of several very trying situations and made me feel independent of outside help, which was very pleasing.

Novel Test for Missing Cylinder.—Frequently my engine misses explosions in one of the four cylinders when under a load, though acting very properly when running free where I can watch it. In order to locate the offending cylinder, I stop the engine and touch each cylinder with the business end of a match. The cylinders which are hot from action will ignite the match, and the offending cylinder will not.

Use Single Tube Tire as Inner Tube.—If you wish to avoid tire troubles you should select a single tube tire of proper size and use it for an inner tube to a clincher casing. If the single-tube tire is too small in cross-section to fill the casing properly, slit an old inner tube around its inner or concave side and place it over the single-tube tire to increase its diameter. Two or even three may be superimposed if needed. Tire lugs will not be needed, and the tire should be pumped up extra tight.

A Priming Kink.—If your motor does not start easily, owing to not getting a rich enough mixture at slow speed of cranking, tie a small bunch of waste with a wire so that it will be close to the air intake of the carbureter. Prime by saturating the waste with gasolene, and the added vapor will make starting easy.

Emergency Filling for Differential Casing.—In case you are unable to obtain oil or grease for the differential casing, beeswax can be used as a substitute, and the car will not skid as much as formerly.

Safe Cranking of the Engine.—The principle involved in safely cranking an engine is to get the explosion when the crank is pulling on the fingers, so that if the kick comes the force will simply pull the handle out of the grasp and not expend its force against the body weight and applied force. Do not attempt to turn the crank all the way around; adjust it to begin against the compression and then give a quick pull upward.

Dry Cells Satisfactory for Ignition When Properly Connected.—Dry cells will give very satisfactory ignition for a four-cylinder motor if you will use four sets of four cells each, coupled in series multiple, so as to get a voltage of only six volts. The secret of light battery consumption, as a rule, is in having the vibrator respond quickly to the traction of the magnet in the coil. The slightest current should open the contact points.

VALVE MECHANISM FOR INTERNAL COMBUSTION MOTORS

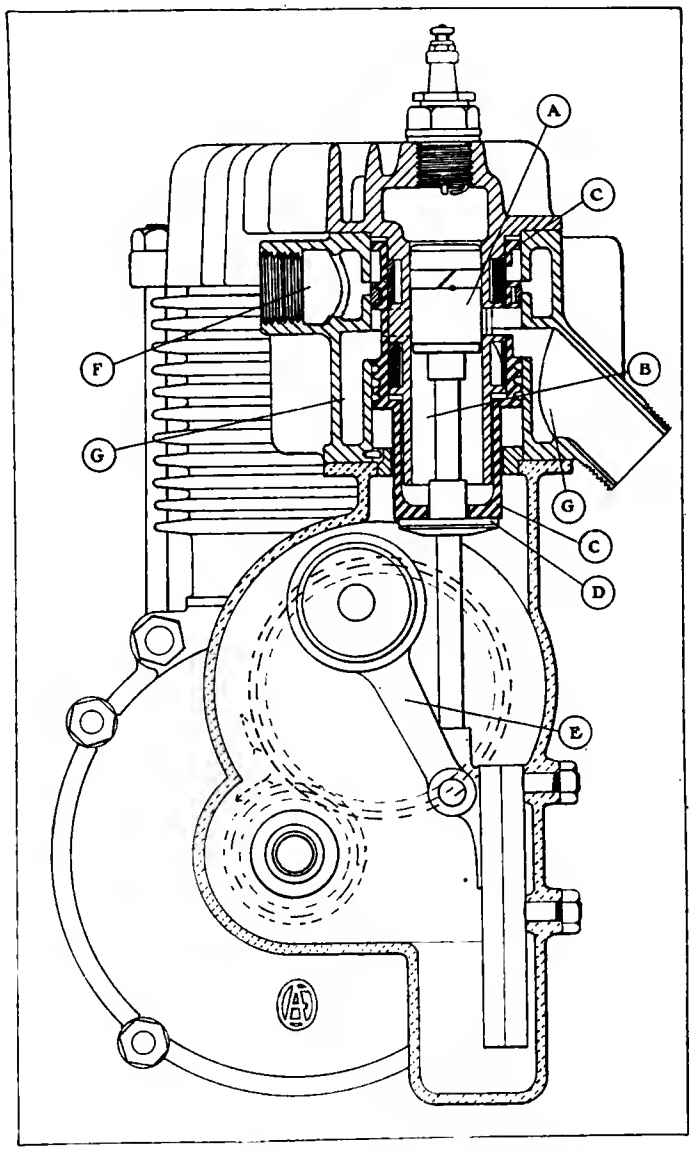
THE majority of internal combustion motors in use to-day are fitted with mushroom-head inlet and exhaust valves working in separate chambers or cages and actuated by cams. There have always been dissenters from this, the received method of valve mechanism, who employ rotating valves, oscillating sleeves and various other devices. Since the demonstration of the commercial success of the Knight motor considerable interest is being taken in such mechanisms and a number of new devices have appeared. The most recent of these is designed to do away with cams and separate valves for both inlet and exhaust and substitute a piston and sliding sleeve which will perform the functions of both valves. In the following description of the mechanism and its action which is that given by the inventor Alden E. Osborn, of New York City, some of the statements have not been proved, as the device is as yet in the experimental stage. He says:

"This valve gearing was invented and designed by me after considerable study and planning of several other forms, and is believed to be new and to possess advantages not only over the present cam-operated valves, but also over other forms of mechanism that have been brought out. The gear shown in the drawing consists essentially of a small piston operating in a cylinder having communication with or opening into the combustion chamber of the motor and combined inlet and exhaust passages in this valve cylinder which are uncovered and put into communication with the combustion chamber by the movement of the piston valve away from the combustion chamber. A means for actuating the piston valve is provided whereby it is given a relatively slow movement at one end of its stroke and whereby it moves faster in one direction than in the other and a valve for throwing the passage above referred to into communication with either the inlet or exhaust chamber of the motor is also fitted.

"In the drawing the main or piston valve *A* is shown in the position it assumes when the motor piston is at the top of the compression stroke, the passage *B* controlled by this piston valve being in communication with the exhaust chamber by the forcing up of the distributing valve *C* by the collar *D* on the piston valve stem. The main valve is actuated from the half-speed shaft by means of a connecting rod *E* pivoted directly on the lower end of the valve stem below the half-speed shaft. The connecting-rod pivot is considerably offset, and this together with the length of the rod, length of valve stroke, size and position of ports and position of distributing collars are so proportioned as to give the correct timing. When the main valve reaches nearly to the bottom of its stroke and the motor piston the end of the exhaust stroke it comes into contact with and forces down the distributing valve thus closing the exhaust *G* and opening communication with the inlet passage *F*, which remains open until the distributing valve is again raised by the collar on the piston-valve stem.

"The distributing valve need not be a very close fit and would be a very light shell both to minimize the shock in removing it and to enable it to be held in place by the ring friction. It should be understood that while this method of operating the distributing valve by the same means as the main valve is new and is very simple, and, it is believed, would be perfectly satisfactory, other methods, such as the operation by a separate crank mechanism or the use of a rotary distributing valve having suitable ports and rotating around the main valve at a speed sufficient to give the correct timing, may be used.

"In cases where high power and efficiency are especially desired the main valve may be in the cylinder head and work downward, thus giving a spherical combustion chamber and a particularly free passage for gases. The cooling of the valves would not present any difficulty, as the only part of the piston valve subject to the hot gases is the top, instead of both top, underside and stem as with the ordinary exhaust valve, and the fresh charge passes through all parts that would be heated, greatly assisting in cooling them. It is believed that this valve system is particularly suited for use with air-cooled motors, it being shown in connection with a small motorcycle motor, but its cooling qualities would be very advantageous in connection with other cooling means. For water cooling suitable passages would be provided around the valves, while in very large sizes the water could even be circulated through the valves themselves. From the foregoing it will be seen that this valve mechanism is of extreme reliability and simplicity, does away with all springs, cams, rollers, etc., eliminates all adjustments, noise and necessity for valve-grinding or other attention and gives a very desirable quick port opening and free passage for both inlet and exhaust gases."



Osborn Valve Mechanism Applied to a Motorcycle Motor.

When Emery Paper Is Forgotten.—Should the autoist neglect to carry emery paper or a swiss file, and the spark plugs need cleaning, a substitute can be found in the igniting composition on a box of safety matches. This can be used in the same manner as the emery paper and, while not quite as good, will clean the plug quite effectually.

Letters Interesting and Instructive

COST OF RUNNING A CAR.

Editor THE AUTOMOBILE:

[1,863.]—I am considering the purchase of an automobile, and, being a man of moderate means, I wish you would give me some information as to the cost of running a car. I do not care for a large car nor a fast one, in fact I would prefer a light slow car to learn on, particularly as I have been told that extra speed costs more.

H. BENSON.

Shenandoah, Ia.

Any figures as to cost of operation would be guess work, unless a person was able to quote you actual figures supplied by a friend, well-known for both careful driving and honesty.

We are fortunate in being able to give you some such figures. These were, however, made in England, and in the consideration of them you should take into account the fact that the roads over there are better than the average roads here. Second year's use of a single-cylinder 6-horsepower Jackson car:

Item.	Cost.	Cost per mile.
209 gallons petrol.....	$63.68	$0.0122
Repairs, grease, oil, etc....	131.81	.0252
Special items, new lamps, etc.	31.10	.0060
Insurance	35.82	.0069
License for car.....	10.23	.0020
Driving license.....	1.22	.0002
Total	$273.86	$0.0525

The above represents the total expense of running 5,210 miles. The driver and owner of the car, says that in the two years he has had the car, he has driven a total of 10,109 miles at a total cost of $512.34, which works out $0.0506 per mile. The above itemized figures then err, if at all, on the side of safety.

These figures selected, at random, so to speak, and showing a total cost per mile for a small light car, such as you would want, of 5 1-4 cents per mile, should reassure you on the score of excessive expense, providing care is exercised.

SOME DIFFERENT RULES.

Editor THE AUTOMOBILE:

[1,864.]—Will you kindly publish whatever data you might have relative to the testing of the different grades of gasoline (that is deodorized, 74 and 76 degrees test) in the way of starting motor, economy, and power. What kind of ether is used to increase the power of motor, and what per cent. of ether to the gallon of gasoline. What are the relative merits and demerits in its use. Would you mention the names of reliable cheap air pressure gauges for tires.

S. KNOX.

Woodbine, Md.

The higher degree test liquids are more volatile, therefore they vaporize more quickly. From this it is easy to deduce that, using them, the engine would start more readily. That is, you could start easier and quicker with 76 degree gasoline than with 64 degree. However, this is just a supposition, as there is no more of either 74 or 76 sold. With the liquid now sold, the interval between any two being less, the noticeable difference in starting effort would be less. As to economy, the same remarks would not hold, as given enough heat to vaporize, the heavier gasolines, which would test up lower, say, about 64 degrees, contain a greater proportion of heat units. They would thus be more economical. The nigger in the woodpile is that they are not pure, and the impurities are higher in proportion with the heavier fluids. Also, there is some question about sufficient heat being present to vaporize.

The usual liquids added to fuels are oxygen carriers. Of these ether, picric acid, chlorate of potash, and pure oxygen have been used. The use of any of them except the latter is to be deprecated, as their presence renders the liquid fuel explosive. The majority of them, also, have a detrimental effect upon the parts of the engine and fuel system exposed. Picric, for instance, attacks cast iron. The first noticeable effect is the rapid pitting of the valves. The percentage varies with the one selected. Aside from increased speed and power, there are no advantages. The increased cost of fuel, of maintenance, and repairs, taken with the explosive nature of the mixture, more than offset this.

The absorption of acetylene gas by gasoline is also used to increase the explosiveness, and consequently, the power from the liquid fuel.

By turning to the advertising columns of THE AUTOMOBILE you will find a number of reliable air pressure gauges for tires, from which you can select one that fits your pocket-book.

HOW TO PAINT BRASS.

Editor THE AUTOMOBILE:

[1,865.]—I am having my car painted and told the painter to paint over the brass parts of the radiator. He told me that the paint would not adhere to the smooth brass after being subjected to the heat of running conditions, but would peel off. Is there any way to prepare brass so that it will take paint and hold it permanently?

F. P. WHITTAKER.

Grantwood, N. J.

The painter was right; paint directly applied to smooth brass parts subject to heat will not stay in place. To prevent the peeling action, have the painter apply a very thin even coat of shellac. When this is dry in place, the paint may be applied over it in any number of coats you wish to have. You need have no fear of the paint peeling off, as the shellac will stand a much higher degree of heat than will ever obtain in a radiator, higher than the temperature of boiling water, in fact, before cracking. If you do not wish to apply a large number of coats, the shellac may be colored, so that the brass will not show through it. In this way, the painting can be completed with one or at the most two coats of paint.

USE OF TWO MUFFLERS.

Editor THE AUTOMOBILE:

[1,866.]—Will you please inform me through the columns of "The Automobile" if better results cannot be obtained by the use of two mufflers instead of one on a horizontal motor. Also advise me if better results can be secured by using double-chain drive on a high-wheel auto with 1 1-2-inch tires, or would you suggest direct rear-axle drive? W. COOPER.

New York City.

If the engine on your car is large enough so that you can spare a little power, two mufflers would reduce the noise very markedly. However, with a properly designed and fitted muffler there should be no necessity for the additional one. All this is said regardless of the type or size of the engine, as the type does not influence the muffling question, while the size only enters in determining the muffler size.

As to the chain versus shaft proposition, the chain is said to have a superior efficiency as a power transmitter, but enclosing it complicates the care and repair of it. The shaft drive, on the other hand, is easily enclosed, and when so covered is clean, quiet, and readily accessible.

A FEW ENGINE QUERIES.

Editor THE AUTOMOBILE:

[1,867.]—Will you please answer the following questions: (a) Which of two engines would vibrate the most noticeably, a four-cylinder 4 1-2 by 6 or a four-cylinder 5 by 5, and (b) which of the two would be most powerful at the same number of revolutions, say, 900 r.p.m., also (c) what horsepower would be considered good with valves in three different positions as: in the head, on opposite sides, all on one side, also (d) what percentage of the actual stroke should the compression volume be? J. M.

St. Paul, Minn.

The force of the explosions vary with the size of the compressed charge, and with the explosion will vary the noticeable vibrations. The size of the charge will be greater with the greater volume swept out by the piston. In the case you cite: (a) this will be 95.4 cubic inches for the 4 1-2 by 6, and 98.2 cubic inches for the 5 by 5. On this basis, the latter would vibrate more noticeably. This is, however, in the nature of hair-splitting, for with as small a difference as this, the difference in vibration could actually not be noticed. All this is on the assumption that the two engines had the same compression. (b) The 5 by 5 would probably develop more power than the other. This is because the bore influences the power as itself squared, while the stroke only enters in the first power. The A. L. A. M. rating for the two would be 32.2 for 4 1-2 by 6, and 40 for 5 by 5. (c) It is not considered that the position of the valves influences the power, although the overhead valve doubtless does to a very slight degree. As between the other two, there is no choice, if power alone is considered. Even with the overhead

valve, this seldom, if ever, is the only thing considered. (d) This varies with the motor, power desired, etc. For a racing motor 1-4, or 25 per cent., would be considered good practice. In ordinary work, 1-3, or 33 per cent., would be more usual. This means 33 per cent. added to the volume swept out by the piston. In designing a motor, the common practice is to figure this so as to get the desired compression. To do this, the formula is used

$$PV^{1.35} = K = 14.7$$

from this, by transformation,

$$V^{1.35} = \frac{14.7}{P}$$

in this P is the desired compression pressure, and V is the ratio of the compression volume to the total volume.

By determining upon the compression, the expression for V is obtained from the above. Then from this, the volume swept by the piston being known, the other volume is readily found, using the equation:

$$V = \frac{\text{compression volume}}{\text{piston volume} + \text{compression volume}}$$

A slight error enters through the use of the constant 1.35, as this has never been accurately determined; however, it is close enough for ordinary work.

MUCH INTEREST IN WELDING.

Editor THE AUTOMOBILE:

[1,868.]—Will you please publish a list of the articles on oxy-acetylene welding or other welding processes which have appeared in the columns of "The Automobile" within the past year? I am very much interested in this subject and wish to read up what has been written on it.

H. M. EAST.

Melrose, Mass.

The following articles have appeared in THE AUTOMOBILE in the past year:

Vol. XVIII, January to June, 1908—"Autogenous Welding in Automobile Construction," pp. 877-879.

Vol. XIX, July to December, 1908—"About Repairing Broken Cylinder Castings," p. 156. "New Method of Autogenous Welding," p. 304. "The General Aspects of Autogenous Welding," p. 781.

HOW TO GRIND VALVES.

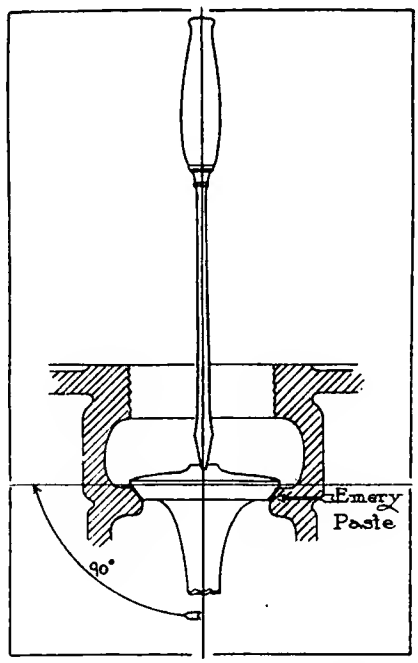
Editor THE AUTOMOBILE:

[1,869.]—I am a newcomer, having recently purchased a car. Some time ago I decided that my valves needed regrinding and attempted to do the work myself. In this I fear that I have done a botch job, for the compression is even worse than before. Will you please tell me how to grind the valves properly?

A. R. SPACKMAN.

Allentown, Pa.

Really, there is nothing to valve grinding except care and the proper materials. First, you will need some very fine emery, the finest you can obtain. Next, this should be mixed to a paste with oil, preferably a light cylinder oil. To use the paste, a screw driver, or if you prefer it, a brace and screw driver bit, will be necessary. Now, have the valve free of its spring, clean the seat off, and spread a very little of the paste over it. Put the valve into place on top of the paste, and with the screw driver or bit turn the valve on its seat about half a turn, then reverse, and turn back half a turn. All the time, pressure must be exerted upon the valve, so that the emery will take hold and cut. Then move the valve around to a fresh position, and repeat the alternate forward and back motions. The first and second positions will have covered the whole circuit, if just a half turn be used each time. In that case,



Showing How to Grind Valves.

the third move should be such as to grind on a space not wholly covered by the previous work.

Beyond this, the only really important point is to have the axis of the valve perfectly square with the seat. If the valve guide has become worn, there is danger of tilting the valve during the grinding process to one side. Then, when in use, it tilts back to the other side and the work of grinding has become useless. There is some danger of grinding off too much. To determine when you have ground enough, note when the pitting has disappeared. After that, grind very little longer before you test the seat. This is done by coating the freshly ground seat with a thin film of red lead, or by smoking it with the flame of a candle. Having thus marked it, set the valve lightly into place and rotate. If you have ground to a proper seat, this rotation will scrape off the lead or carbon used in a continuous ring. It does not matter how wide this ring is, but it must be continuous.

CARBURETER TROUBLES.

Editor THE AUTOMOBILE:

[1,870.]—I have a new automobile, Buick Model F 22-horsepower, on which I had installed a Remy magneto. I find whenever I get in a heavy pull and open the throttle pretty wide, my engine backfires in the carbureter. It never does this on smooth road, although I may have the throttle open wide. When I run on the batteries, I rarely ever have a backfire in carbureter, but when running on the magneto and in a heavy pull, it does backfire. I have used new spark plugs and new batteries, but it doesn't seem to remove the trouble entirely, although it helps a great deal.

If you can explain the cause of this, I will greatly appreciate it. I thought perhaps it was carbureter trouble, but have changed carburetors and still have the same back firing, so I know my carbureter is O. K.

ROY N. CHELF.

Brooksville, Fla.

From the record of your troubles we would have said the carbureter was at fault, but it appears that you have obviated any possibility in that direction. About the only other solution is that the magneto is slightly out of time, say to the extent of one tooth on the driving gear. As the result of this, on slow speeds and even at high speeds with but little load, the effect is not bad enough to be noticed. When working under a heavy load, however, even a slight error in the timing would be greatly magnified. The same results might be caused by the valves being incorrectly timed, possibly by the same small amount, that is, one tooth out of the way in the meshing of the driving gears. In case that a remedy for the trouble does not result from making the changes indicated above, look at your inlet valve springs, or to anything else that could possibly cause the inlet to close late or slowly. Look at the valve seats to see if they are in good shape, and finally read letter (1849) in the April 22 issue of THE AUTOMOBILE relative to the correction of sticking valve stems. If your trouble persists after trying the other remedies, try fixing your valve stems.

MORE RED-HOT PIPES.

Editor THE AUTOMOBILE:

[1,871.]—Will you please publish the following in answer to the letter from J. T. D. relative to a red-hot exhaust pipe (1835)? I have had similar trouble and after much working around and trying of new schemes and suggestions from others, I found that my muffler was clogged, and upon cleaning it, found a little improvement. This was not enough to satisfy me and I continued working on it until I finally decided that the trouble lay in the design of the muffler. This was so designed that there was too much back pressure upon the engine. The result was that it made the exhaust pipe into a radiator by allowing all the heated gases to remain in it. As each fresh supply remained in or was forced in, there resulted a constant increase in the temperature. Finally, this arrived at the point where the exhaust became red-hot, and as far back as the cylinders.

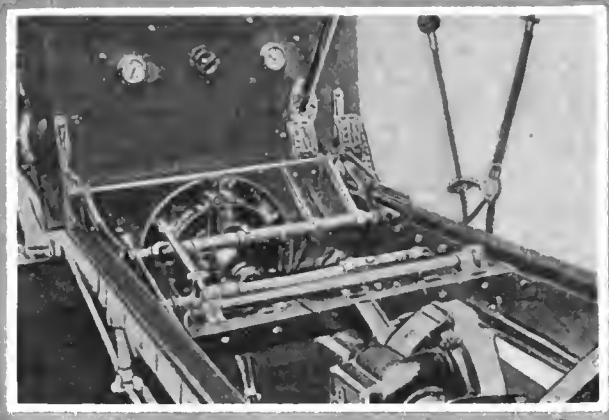
Upon arriving at this conclusion, I bought another muffler on trial, and as it proved satisfactory, I kept it. My hot pipes have entirely disappeared since putting the new one on.

V. K. MALONE.

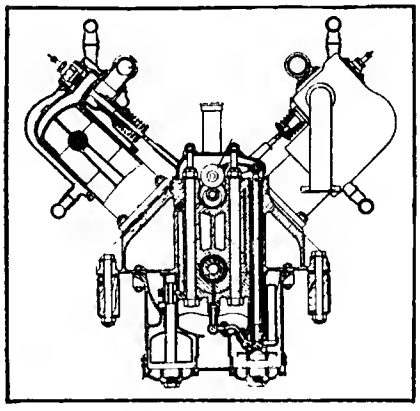
Kansas City, Kan.

This brings out very clearly a point that was not touched upon in the answer to J. T. D., published in the issue of April 15. The point is well taken, and should be kept in mind by anyone having trouble with pipes heating up. Many think this necessary, but it is not.

French Newcomer with Aerial Engine



PARIS, May 1.—One of the largest producers of aeroplane engines in France is about to turn his attention to automobiles, and the advance notes of the car to be produced are of more than passing interest. In fact, to the casual observer, some of the details are in the nature of an amazing departure from current practice. The power plant details, in particular, present some new ideas adopted from aerial practice which will doubtless provoke much discussion. Aside from the new and advanced features, the general appearance of the finished vehicle is not unlike that of a number of other French cars, as Renault, C. G. V., and the recently described Ampere.



Cross-Section Showing Oil Pump.

The possible openings for discussion are shown by the statement that the engine used is the same as the one supplied many prominent members of the aerial brigade, viz., an eight-cylinder of extremely light construction. This gives an opportunity for a revival of the old discussion as to torque of motors with more than four cylinders. Is the torque more even than the four, to more than make up for the extra weight and cost? That is an open question, at least as to cost; but on the subject of weight the E. N. V. scores heavily, as, being built primarily for aerial use, where weight is reduced to the absolute limit, the ratio of weight to power is very low indeed. This will satisfy the advocates of light construction who are not partial to the air-cooled engine; in fact, this motor goes even the latter one better.

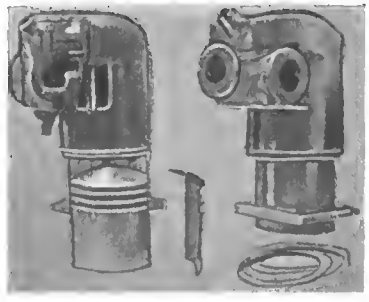
Thus the total weight of the engine alone is 330 pounds. At the moderate speed of 1,000 r.p.m. the power developed is 50, while by speeding up to 1,500 r.p.m. or more, 75 horsepower may be had. The former is 6.6 pounds per horsepower, while the latter speed reduces the ratio to 4.4 pounds. Putting this motor into a car will, with a car weight of 3,300 pounds total, be in the ratio of 44 pounds, which is less than the best "four."

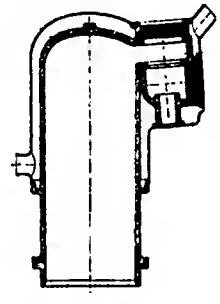
Distinctive Features of the Engine.—The engine presents many distinctive ideas in automobile practice. The cylinders, 100 mm. (3.94 inch) bore by 130 mm. (5.12 inch) stroke, are set at an angle of 90 degrees to one another. In this manner there are two groups of four cylinders on each side of the axis of the motor. The cylinders are cast separate, without water jackets, and are machined both inside and outside. This process results in each of the castings being of exactly the same weight as every other one, and the resultant saving in the total weight is considerable. Moreover, it allows of a much lighter cylinder casting than could be successfully used otherwise.

The position of the outlet and inlet for the exhaust and the carbureted gas are peculiar. The outlet is located at the side of the cylinder casting, and the castings are so placed that number one cylinder in both groups exhausts at the front side, while number two exhausts at the rear side. Three and four are just like one and two, so that there are four individual exhaust pipes on each side. They are conducted into a header, these being placed below the crankcase on each side. From each header, a pipe leads straight back to a muffler. In this arrangement not only does each group of cylinders have its own exhaust pipe and muffler, but down as far as the exhaust header each cylinder has an individual outlet.

The inlet, on the other hand, is placed in a position which would be best described as the middle of the front of the cylinder casting. This brings, when the motor is assembled, all of the inlets on the inside facing one another. Short pipes connect them, and from the middle of these—that is, exactly between cylinders two and three—a pair of pipes of drawn copper tubing lead to the carbureter, placed in front of the crankcase.

The waterjacket, of copper, is not riveted in position nor held by a junk ring, as is usual, but is the result of electrodeposition, all joints being thus proof against leakage. Moreover, so closely is the copper joined to the cast iron of the cylinder that it is impossible to distinguish the exact point where the iron leaves off and the copper begins. It is a method which has but one disadvantage, that of first cost. The water space is determined with accuracy, while minimum weight is obtained.



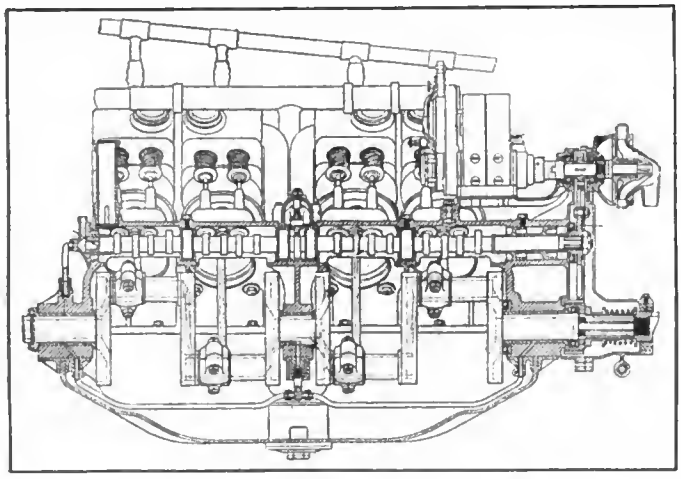


Cylinders Have Electrically Deposited Water Jackets.

The valves are not placed in the head, as is the ordinary practice with very light engines, but are placed side by side on the inside, so that a single camshaft operates the valves of all cylinders. The camshaft, for the operation of these valves, is machined from the solid metal, resulting in rigorously accurate cams, and again the extreme lightness is favored. The drive of the shaft is by means of a spiral gear of very large diameter. This means low friction losses and very quiet action. The cams are of a variable shape, from the point exactly under the valve outwards, and the shaft is slidable in a longitudinal direction.

The driver of the car has at his disposal the manipulation of this shaft, so that he may vary the lift of the valves at will and thus, if he so desires, effect the maximum fuel economy.

Very Lightweight Four-Throw Shaft.—The crankshaft is a fine piece of machine work. The circular webs are turned out, both inside and outside, and the crank pins are also drilled through. The shaft is of the four-throw variety, and, except for the great length of the pins, is not different from any ordinary crankshaft. The circular webs, which are heaviest at their extremities, or rather peripheries, in this respect aid in the flywheel action and allow of the mass and weight of the latter being reduced. They also increase the balance of the motor as a whole because of their location. As to balance, this is not quite as good as the six, but the difference is small. The longitudinal



The Longitudinal Section Displays the Crankshaft.

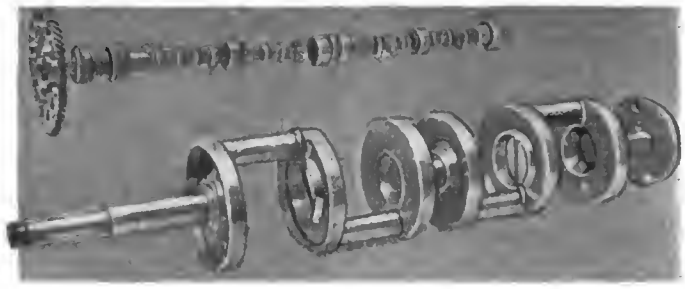
couple is balanced, which is not the case with the six. The transverse couple, similar to the six, is completely balanced, and, in common with the fewer number of cylinders, the primary force is unbalanced. This, however, is very small on the sextuplet arrangement, while, with the eight it is very high.

The largest variation of energy due to the moving parts, or, more correctly, the reciprocating parts, is lower than the same for the more common sixes. So, too, the figure for the energy ratio is less than half that of a six, this being advantageous.

The torque is more uniform than any six, consequently the shocks to the parts of the mechanism are less, and the necessity for changes of speed are even less than in a six, one of the latter having been operated without a gear box.

Size and Length of Main Bearings.—Plain bearings are used and are of exceptional length, that is, at the ends. These have a length of about two and a half times the diameter of the shaft, which is, itself, of a very large size. The crank pins are of the same diameter as the bearings, and the pin length is also two and a half times the diameter.

The connecting rods are offset and have the ordinary I-section. The piston and rings, together with the piston pin and its method of fastening, present nothing novel. The piston has a domed top, which is machined all over. This procedure is expensive, but saves weight, and by making the pistons more nearly alike contributes very materially to the balance. Three rings are used, all placed above the piston pin, but another ring, or, more correctly, a lip, is turned into the inside of the bottom of the piston. This



Camshaft and Crankshaft Are Made Very Light.

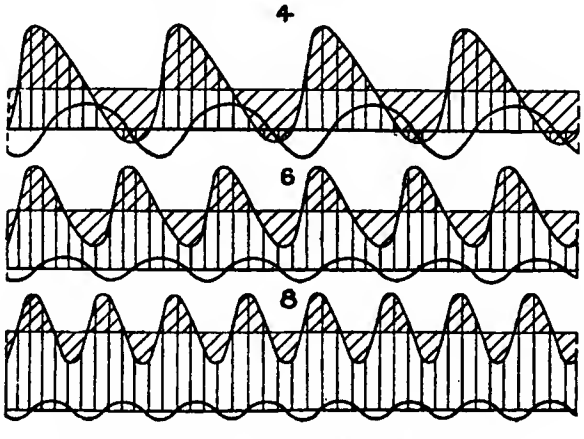
catches and retains the surplus oil, and feeds it through small holes to the cylinder walls.

The lubrication differs from this construction in that it presents some element of novelty. Lubrication is of particular importance on an engine of as fine constructive workmanship as this one, for its very fineness would be less protection against the lack of oil than would the inferior but larger parts of a more husky machine. The lower part of the crank chamber forms an oil tank. The level of the liquid in this is controlled by a float. A lubricating pump driven off the end of the camshaft, the rear end, by the way, delivers a constant supply of oil to the central and main bearings of the main shaft, as well as the camshaft bearings. Both shafts are hollowed out, so that the oil circulates through them. The crank, in addition, is bored at all of the pins, so the oil circulates directly to them. The round webs are also bored and from them to the upper end of the rods a connecting tube of copper leads the oil up to that point. All surplus oil from the mechanically lubricated bearings flows to the crankcase, where it is led into the special chamber, from which the float regulates the return flow.

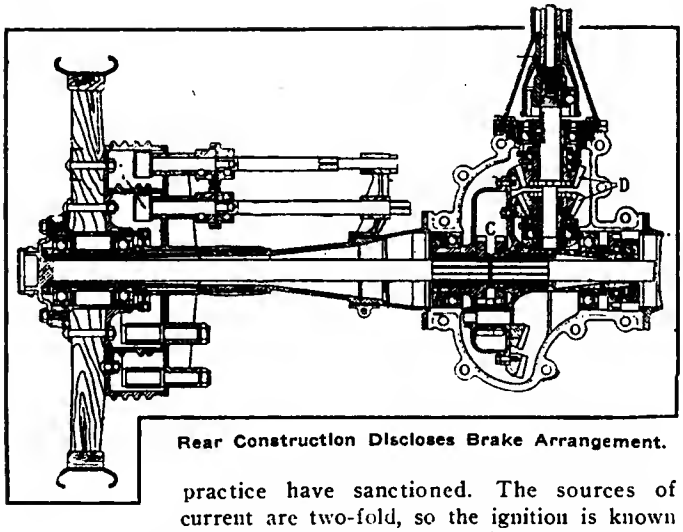
The water is also positively moved around by means of a large diameter pump of the centrifugal type. This is located on the extension of the magneto driving shaft, midway between the cylinders and rather high up. The magneto being driven at crankshaft speed, the water is moved at this same high rate. This high flow rate allows of somewhat smaller diameter water pipes, showing the faithful attention to small details which has resulted in the unusual weight reduction.

The water outlet is on top of the cylinders, from where a gradually increasing sized pipe leads up to the water tank. The pipes for the two groups are separate and enter the water tank, placed on the front of the dashboard, on opposite sides. The radiator is placed, C. G. V. fashion, forward in front of the engine and rather low down. An air-tight bonnet above the engine and an air-tight pan below it force the air after passing through the radiator to do double duty by passing over the length of the engine, in which cooling action is gained.

Ignition Is Regular Except for Magneto Position.—The ignition system presents those features which time and modern



Torque Curves for Four, Six and Eight Cylinders.



Rear Construction Discloses Brake Arrangement.

practice have sanctioned. The sources of current are two-fold, so the ignition is known as double. Storage batteries and a high-tension magneto are provided, the latter being mounted in an unusual position. This, on a shelf or platform formed by the upper half of the crank-case, is located midway between the groups of cylinders. It is closer to the front end than the rear, being nearly opposite to the first pair of cylinders. It is driven from the camshaft by means of a silent helicoidal gear, and carries the water-pump on its outer or forward end. It turns upon ball bearings, which are arranged to take thrust in both directions, thus caring for any possible thrust either from the pump or from the driving gear. A slip joint in the magneto shaft allows of its ready removal without disturbing the pump or driving arrangement.

Short Bonnet and Low Center Line Very Noticeable.—The construction of the motor is such that it takes up no more space longitudinally than any four-cylinder vertical of the same size would. From this the bonnet is short, much shorter than would be expected from eight cylinders. Another characteristic, noticeable at once, is the low center line. The low flat position of the cylinders allows of the center line being kept very close to the ground. In this way the center line is at the same level, and the straight line drive is obtained.

The first step in the transmission of the power from the motor to the road wheels is a band clutch. The two bands, fitted in a groove on the large diameter flywheel, are attached at their extremeties to the ends of pivoting levers, in such a way that they have free movement and can shape themselves freely to the form of the flywheel. To clutch, the pivoted levers are so moved that the bands grip the surface of the flywheel. The operation of these levers is interesting. The inner extremities opposite to the bands carry toothed sectors, which are connected by an inclined shaft. This bears an external toothed gear, the movement of the shaft operating the sectors and the levers.

Three-Point Suspension for Transmission.—The transmission is located back of the middle of the chassis, being hung on a pair of cross members. These are of an inverted U-section, the metal being pressed steel of large breaking area. The forward support is straight, but the rear one is made with a deep drop. The depth is made necessary by the low position of the shaft. The cross member passes down and under the transmission case, while an additional short cross piece stiffens it above the shaft. The latter is of a U-section, and is a casting.

The transmission proper has a number of peculiar features. the speeds are four in number, although the eight cylinders are so flexible and give so even a torque that no transmission would be necessary. Of these speeds, two give a direct drive. The most noticeable point about the gear box is that it contains but two of the speeds and the reverse, the other two being incorporated in the gear box at the rear axle. The box in the middle of the frame gives the first, fourth and reverse. The case combined with the differential housing carries the gears which give second and third speeds.

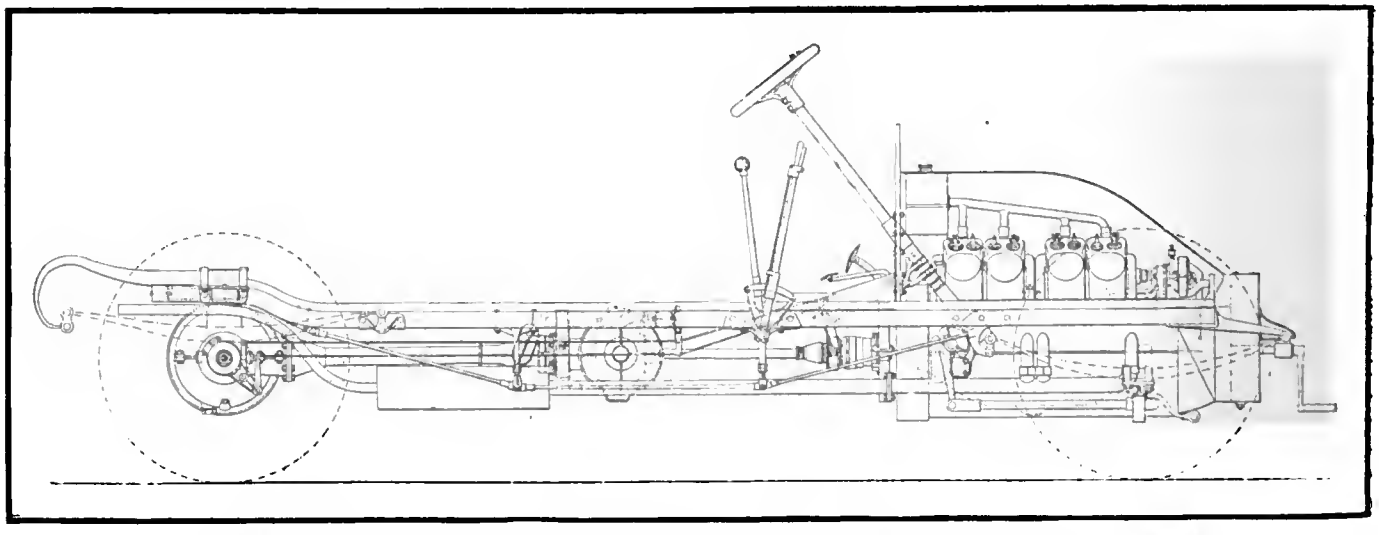
Unusual Rear Axle and Speed Combination.—From the gear box to the rear axle the drive is carried by means of a propeller shaft and special universal joint. This is on the order of a pair of semi-circular hollow forks, which are free to slide around in the grooves of a spherical block. The latter is grooved in two directions, so that the forks, when in place, lie in two different planes, at right angles to one another. The rear end of the universal forms the clutch, which gives the change of speeds incorporated with this construction. To do this, a freedom of motion along the shaft is necessary, and the peculiar universal joint allows this.

Peculiar Universal Joint.

A differential of the spur type is used, to which two bevels are attached. Two gears on the cardan shaft mesh with these, and by means of the clutch, just described, are thrown into or out of engagement.

The shaft is enclosed in a tube of large diameter and very thick, which acts as a radius and a torque rod at the same time. This forms a part of the rear housing, when in place, and is flexibly mounted at the forward end. From the differential housing of large diameter, to the spring seats, which are formed integral, the axle tube is of a tapering section.

The frame is of armored wood, a double truss reinforcing it between the springs. These are semi-elliptic both front and rear, the rear end of the frame being carried out rather far, and a dumb iron fastened to it carries the spring. The construction is such as to give the impression of a three-quarter elliptic. The front springs are of the very flat semi-elliptic type.



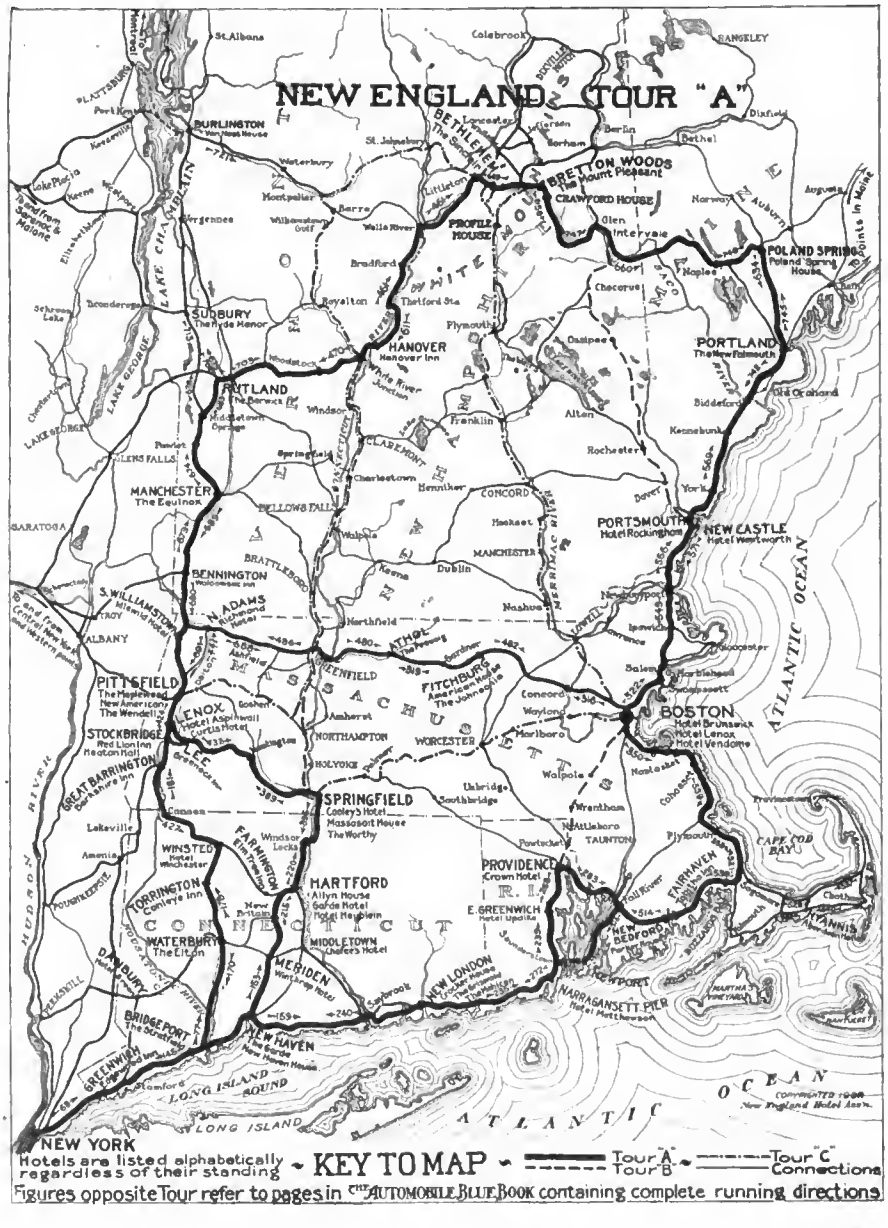
Complete View of the E. N. V. Eight-Cylinder Chassis, with Four Speeds and Armored Wood Frame.

NEW ENGLAND OFFERS MUCH TO AUTO TOURISTS

WHEN one plans an extended tour a great aid is the possession of a map from which one can gain a general idea of the territory to be visited. New England has diversified scenery, excellent roads, and hotels capable of supplying maximum comforts at reasonable prices. While one tourist may desire to plod along leisurely and make the day's run of reasonable length, the next man may find it necessary to utilize his time more sparingly and thus be compelled to drive from early sunrise to late sunset.

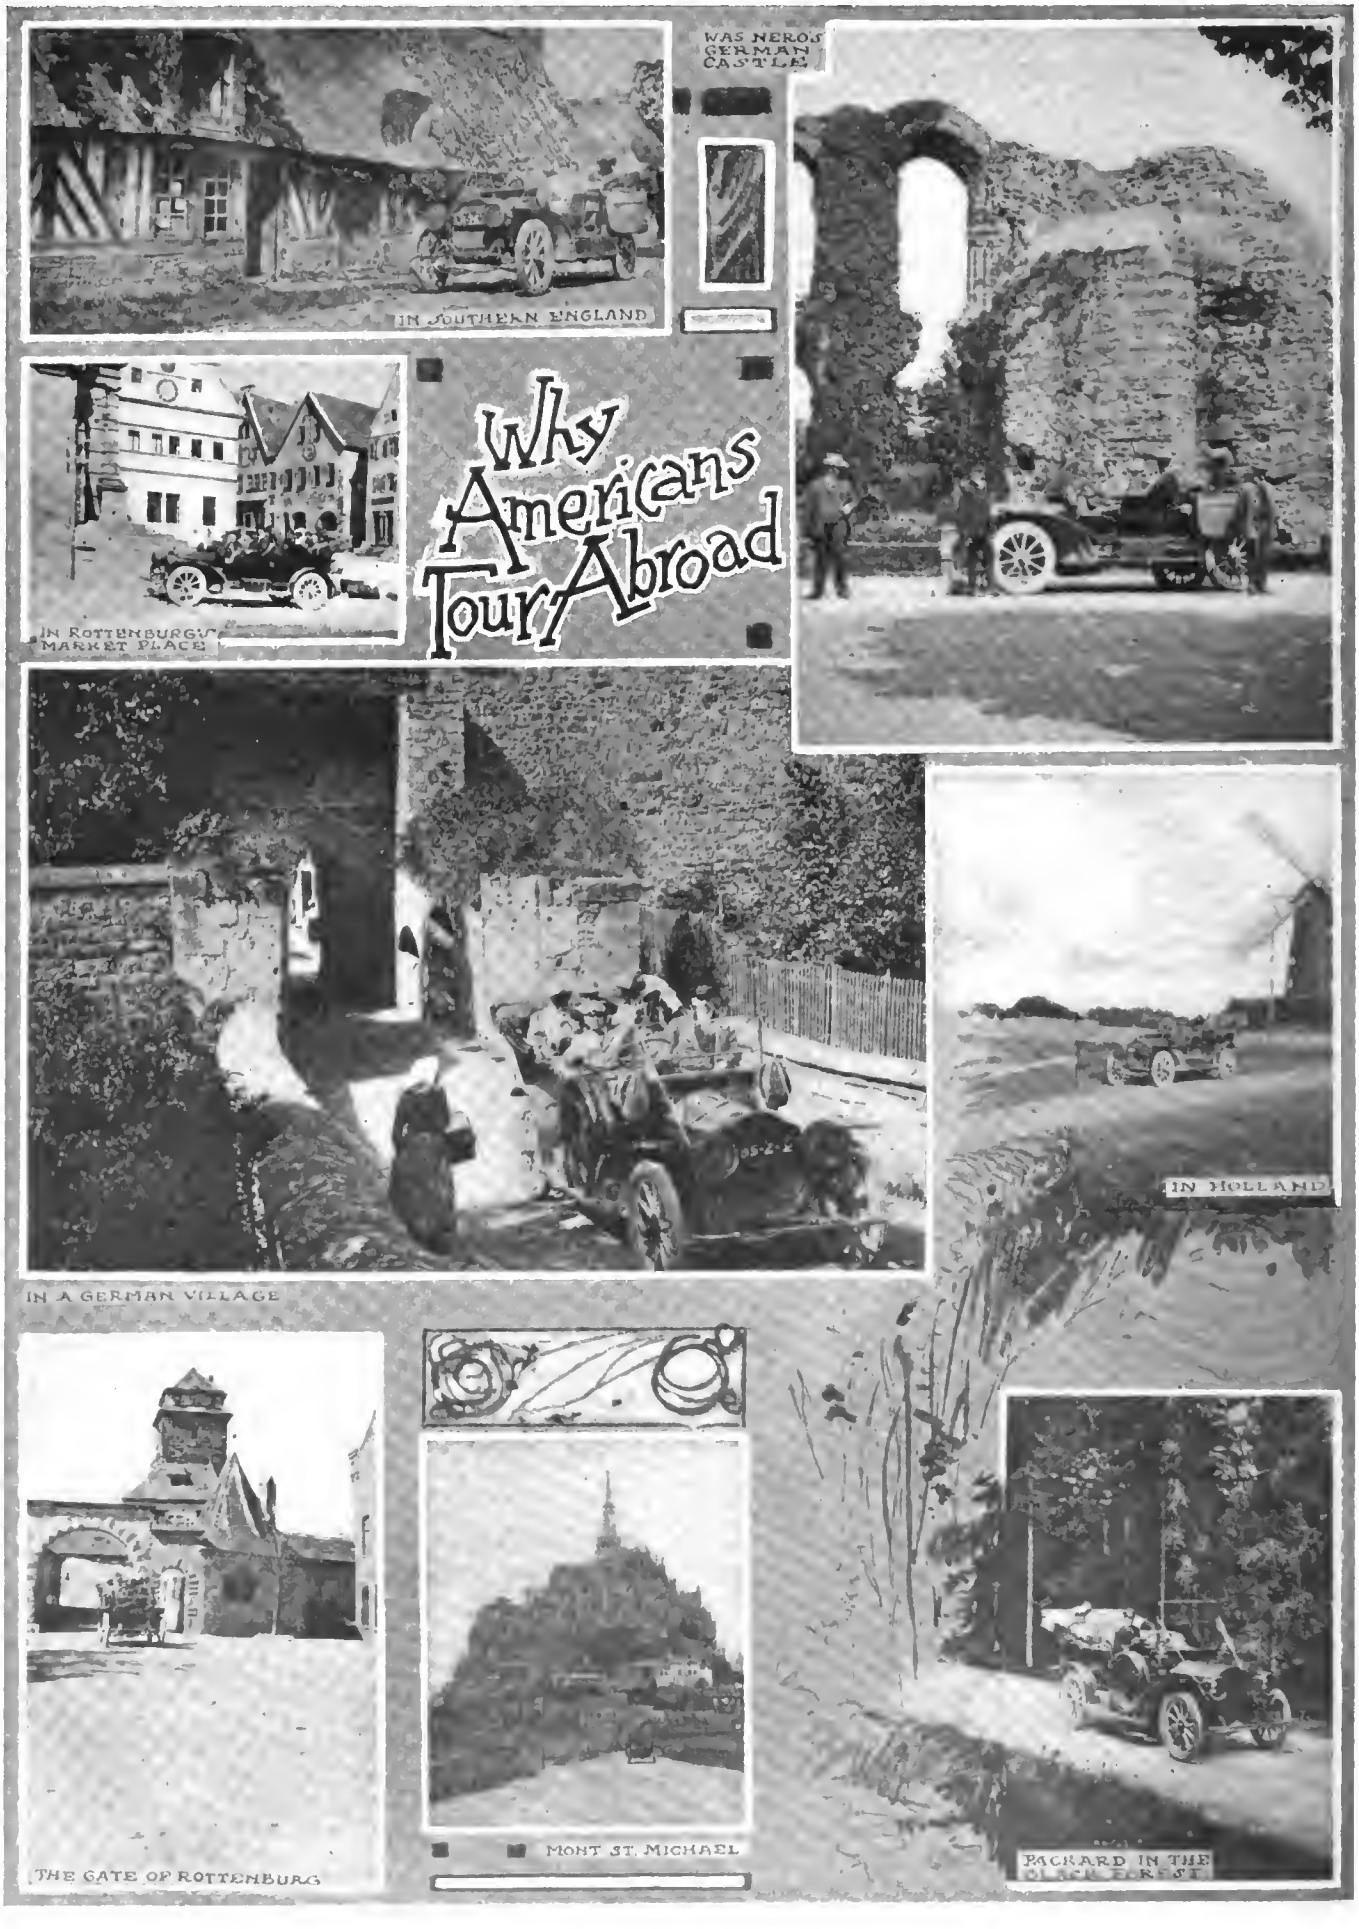
Comfort in touring means a good night stop, either in a spick-and-span New England city, or else at some picturesque resort by the seashore or in the mountains. And New England has cleanly cities and towns, rugged, foliage-covered mountains and peaceful valleys, and also possesses a coast line along which one can drive to the music of Old Ocean's ceaseless roar.

As an aid to the thousands of visitors who this season will enjoy six of the original thirteen States, the New England Hotel Association has outlined three tours for those tourists who do not want to be bothered too much in planning their own routes. The association is distributing folders containing a comprehensive New England map on which the three routes are emphasized in such manner as to give a clear idea, and also include a diversity of side trips and unlimited opportunities for "exploring" in in all directions from the beaten path. These maps contain a reference to the pages in the "Official Automobile Blue Book," which give the complete running directions. Any one of the hotels belonging to the association will, upon written request, supply the folder maps.



Herewith New England Tour "A" is given and it will be supplemented with Tour "B" and Tour "C." Tour "A" follows the shore line from New York City to New Haven and New London, and then goes to Providence, swings around toward the Cape Cod country, and finally reaches Boston. Northward the route is to Portsmouth, then to Portland and Poland Springs. Next comes a westerly course through the White Mountains, then the Connecticut River is followed, after which the Green Mountains are crossed to Rutland. Vermont and western Massachusetts are covered, with the option of returning by two routes from Lenox—one going through Springfield, Hartford and Meriden, and the other by way of Winsted, Torrington and Waterbury. Of course it is possible for one to modify the trip in various ways: for instance, from Boston to Pittsfield, Athol, Greenfield and North Adams, which supplies an interesting cross-State tour. Indications are that New England will see more automobile tourists during the coming season than ever before since the appearance of the motor-driven vehicle, and the preparations being made insure excellent treatment all along the line.

Another Blue Book Section.—The 1909 edition of "The Automobile Official Blue Book," Section No. 1, for New York, Canada and the West, is off the press. In this edition the Class Journal Company incorporates considerable additional road information throughout the territory. It is a leather-covered volume of 720 pages, covering in more detail than ever before the territory in New York State and portions of Canada, to which is added, for the further convenience of the tourist, the Erie — Pennsylvania—section, whose routes, on account of their peculiar location, enter both the territory of the New York State book, the New Jersey-Pennsylvania volume, and also the Middle-Western volume. In the first part of it is used an entirely new map of New York State. A new feature is a key supplied this map, which plan is carried into the index by a letter and figure, reference to which will enable the tourist to look up any place desired quicker and easier than has heretofore been possible. The index itself has been broadened in many ways, and a large number of smaller places have been added to the former lists. The great amount of road improvement on the lower west side of the Hudson River has furnished tourists a considerable number of new routes. Of the routes printed for the first time this year, one of the most notable is that from Montreal to Burlington, Vt., which will be found in the Canadian section this year, including odometer mileages, and a map specially drawn.



AMERICANS FORMULATE EUROPEAN TOUR.

Automobile touring parties who are looking forward to spending the coming Summer abroad are already starting for Europe. Three Franklin cars, respectively from Denver, Oakland, and Salt Lake City, are in the van in this European invasion, with parties that will in their travels cover all the countries between Spain and Norway, Scotland and Turkey. The plans of the tourists are outlined as follows:

From Salt Lake City.—Starting on a tour of no less than ten countries, George T. Odell and party from Salt Lake City recently sailed from New York on *La Provence,* and in the course of the next four or five months they will travel between 6,000 and 7,000 miles, using a six-cylinder car.

Landing at Havre, the tourists will go to Paris and Bordeaux, and thence into Spain, there visiting San Sebastian, Saragossa, and Barcelona. Returning to France on the way to Italy, they will visit Montpelier, Marseilles, and Monaco, and in Italy will follow a route leading through Genoa, Florence, Rome, Milan, and Venice. In traversing Austria the party will tarry at Vienna, and in Switzerland at Zurich. Through Germany, by way of Munich, Stuttgart, Leipzic, and Berlin, the travelers will go to Luxemburg, and thence, by way of Ghent in Belgium, back to France, whence from Calais they will cross to England, going from London to Plymouth, Shrewsbury, and Newcastle. Crossing the Scottish border they will visit Edinburgh, Inverness, Wick, and Aberdeen. Returning through England, by way of Carlisle and Chester, they will make Liverpool their port of departure for home.

From Oakland, Cal.—Setting out on a tour of Europe which will extend over 10,000 to 12,000 miles and continue from six to nine months, Mr. and Mrs. Walter Morgan and Mr. and Mrs. A. F. Cornwall, of Oakland, Cal., are about to sail from New York on the *Rotterdam.* Landing at Boulogne, they will take a Franklin touring car, which has been shipped to Havre by another boat, and thereupon begin their wanderings, which will extend over the Continent and the British Isles.

The first four months will be spent in the countries of the Continent; then will follow two months in and about England, after which the tourists will spend a month in Norway and Sweden. In November they will leave the car and start for Egypt.

From Denver.—Shipping his automobile, a seven-passenger, 42-horsepower Franklin, to London, Dr. J. W. Harris and party will, June 15, leave his home in Denver for a tour of the British Isles and France. Arriving at London, he will tour north to Cambridge and York, and thence to Edinburgh and Inverness, then back to Glasgow, through the Burns country, and will cross to Ireland. The party will take a trip through the north of that island, going then to Dublin and south among the lakes of Killarney. Crossing to Wales, the tourists will traverse the north of that region and on the way back to London will visit the Shakespeare country and Oxford. Going to Folkstone, they will ship the car to Boulogne and will then spend three or four weeks in touring France.

HOYT SAYS AFRICAN ROADS ARE MAGNIFICENT.

New York City, May 3.—After a 5,000-mile motoring trip, Colgate, Hoyt, ex-president of the A. C. A., arrived home recently. He came direct from Southampton, but spent the month previous in Northern Africa, where his party toured from Algiers across an oasis in the desert to Biskra. Thence their route lay through the desert toward the northeast coast of Egypt and finally along the Mediterranean to Tunis, where they took a steamer. Many ancient cities were passed, including Carthage and Kabrouan.

Although warned of brigands, the trip culminated without any untoward incident. Speaking of the African part of the tour, Mr. Hoyt said: "We were all enchanted with the coast roads to the eastward of Algiers. Most of the roads were even superior to those of France. The trip was magnificent, whirling away over mile after mile of sand, ancient cities and historic spots."

MAXWELL PERSONALLY CONDUCTED TOUR.

One of the most novel tours of the Summer will be that which the Maxwell-Briscoe Company are now arranging for the early part of June. This will take the form of a pleasure tour, closed to Maxwell owners and the running schedule will be very easy. The daily mileage will not exceed 100 miles, over the most attractive roads of the eastern parts of New York, New Jersey and Pennsylvania.

No entry fee will be charged, and a number of interested Maxwell owners, who do their own driving, have already signified their intention of taking in the tour.

Starting from New York City, Monday, June 14, the tourists will proceed up the Hudson to Tarrytown, and thence via New Haven and Waterbury to Springfield. From there the route goes through the Berkshires to Poughkeepsie. The third stage will carry the Maxwellites over into Pennsylvania, by way of Port Jervis and the Delaware Water Gap to Philadelphia. Jersey will then be crossed to Atlantic City, where the tourists will rest over Sunday, the 20th. On the following day the return trip to New York will be made, traveling via Lakewood.

Victor Breyer at His Desk in His Paris Office.

FOREIGN A. A. A. TOURING ARRANGEMENTS.

Members of the American Automobile Association who expect to tour abroad this Summer will be interested to learn of the creation of a European touring bureau specially adapted to their needs. The main object of this bureau is to provide all members of the association going abroad with any information or help they may require. Its services are to be entirely gratuitous, except, of course, in cases where unusual expense is involved. The management and direction of this bureau has been intrusted to Victor Breyer, who is well known to the automobiling fraternity, both in America and in Europe. He has been one of the leading writers of the European sporting press for nearly twenty years, and is thoroughly conversant with the English language, as well as with American methods and customs.

For the benefit of association members who wish to rent cars, either by the day, week or month, arrangements have been made with the best Parisian firms whereby they can secure special rates. Care will be taken to secure good cars and competent chauffeurs, and any complaints will be thoroughly investigated by the association, and measures taken to remedy them. A scale of prices for this service, varying according to power, number of passengers, and distance to be covered, will be sent on application. Mr. Breyer's address is 4 bis, rue Descombes, Paris, France.

The Riviera Gateway into ITALY

By FRANCIS MILTOUN

NO softer, more delightful automobile touring ground exists than the French and Italian Rivieras; and Italy, too, is now becoming the vogue among automobile tourists, as it has been for long years past with all other classes of travelers.

Taken all in all, that wonderful strip of Mediterranean coast-line, from Marseilles to Genoa, has not its like on earth for picturesqueness and historic souvenirs, and it is blessed with good roads, too, throughout its length of four hundred odd kilos.

The Riviera gateway to Italy is the peer of all others for making one's entrance into that romantic land. While the Swiss-Italian and Franco-Italian passes are still snow-bound, or running rivers of slush and mud, one may pass the Pont Sainte Louis, between Menton and Vintimille, at sea level, amid the flowering blossoms of an early Spring, and between groves laden with oranges and lemons.

The itinerary is an historic one, and there is not a kilometer of the way but has a reminder of some Roman Antony, or a fleeing Pope, or some confident or down-hearted Napoleon.

We set out to cover the ground again, though already well known to us by road and rail; this time *en auto*. We set out from a little Mediterranean fishing village on the shores of the Golfe des Lions, where we had passed a happy Winter with a crew of artist folk.

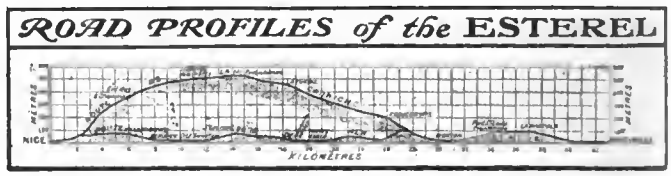
The sunsets and the quaint customs of the fisherfolk, and the rare old house fronts, and the canals and quais of Martigues, the Provençal Venice, were quite different attractions from those to be found in the resorts out East, and more, much more, to our liking; and so it was that we had lingered on at that delightful spot the whole Winter through.

Just as King Carnival was sending out his invitations to come and visit his cities of pleasure of the real Riviera, his *battailles des fleurs*, his *bals* and *fêtes* and *veglioni*, our thoughts turned thither, not to rest within his realm, but to pass through, simply, en route for Italy, where the genuine romance life of the Middle Ages still pursues its course, or something not very far advanced beyond, in many a little town of the Tuscan hills and Lombard plains, unspoiled by any such interpolations as the super-refinements of the Côte d'Azur, the world's loveliest and most dissolute playground. Italy is backward; there is no doubt about that, in the small towns at any rate; thougb Milan and Turin and Rome are as advanced as "Young Italy" can make them.

A Nicios Whom We Met While On the Route.

We were three, the author-méchanicien-chauffeur and two in the tonneau, when we set out from Martigues. We dodged around Marseilles and its twenty kilometers of horrors in the shape of badly-paved and worse encumbered roadways in and out. The automobilist down from Paris—if be knows his way about, and sticks to the "Route d'Italie" via Aix-en-Provence, leaving that leading into Marseilles to the right—does the same.

Just east of Marseilles we dropped down a red earth hillside into the little town of Cassis, there to renew acquaintance with another artist colony of folk, snugly quartered in the immaculate *chambres hygièniques* of the quaintly-named Hotel Cendrillon, a modest inn which would never have existed at all had it not been for the initiative of the Touring Club de France, which pointed out the way and showed why and how it should be done. Result: happiness and prosperity for the proprietor, and contentment for the guests. Such a hotel is, of course, a success. Some English and American country innkeepers could get some points at the Hotel Cendrillon, if any of their craft should ever come this way.



For sheer charm and beauty Cassis runs Martigues a close second, and the hotel is a wonder, and so is the white wine of Cassis, which is drunk as the accompaniment of fish and oysters. For these, and some other reasons, we found Cassis not at all bad, though we had a hair-raising fright as we dropped down the 10-kilometer slope of its hillside, with *lacets* and *virages* that were terrific, finally to land on the very quais of Cassis' little port itself. To get away again it is a 10-kilometer climb skyward, of course.

"Ate and slept well, and off again at daybreak," as Pepys would have said; following the coast-line eastward past Toulon to Hyères, one of the least-traveled itineraries (65 kilometers) of southern France, and one of the most delightfuly environed. The main "Route d'Italie" passes through Brignoles and Le Luc, only coming down to the coast at Fréjus, 121 kilometers from Aix-en-Provence. One may take his choice, the main road is considerably "faster," though not much shorter, and decidedly less attractive.

After the magnificent road skirting tbe Bai de la Ciotat, its great Bec de l'Aigle pushing far out into the Mediterranean blue, the wondrous color of its waters and the green of its shores, one comes to Bandol, an incipient watering place, with a promenade lined with palm trees along the sea front (the gift of some Pacha from Constantinople, exiled doubtless for his country's good) and a "good-enough" hotel (de la Marine), of the conventional order, where one gets tourist fare instead of that of the country. There was another heart-breaking drop down from the road on the height as we came down to sea level at Bandol, but the brakes held and nothing happened. One must go slowly though; these finely-graded and well-surfaced French roads look often less steep than they really are, and it's a mighty easy manœuver to slip down at a dangerous pace when nothing is in sight, but more difficult to pull up suddenly if one has to.

After Bandol it was flat, easy going via the rocky Gorges d'Ollioules, always along the coast, via Sainte Nazaire du Var—where the trade in early Spring hyacinthes and narcissi has completely absorbed the population, who used to make a living at fishing, by Tamaris—where Georges Sand laid the scene of one of her romances, and so on and by Toulon—by Toulon and its great arsenal at *pleine vitesse*, for no one ever stops at Toulon unless he has to—and with good reason. Finally, 18 kilometers beyond Toulon, one reaches Hyères.

We lunched pompously at Hyères, in the vast Hotel des Isles d'Or, amid fifty or more English and American and five lonesome Frenchmen. If you don't care for that sort of thing don't come here, but go to the Hotel de France; it is of the soil and will do you quite as well in the feeding line, though less luxuriously. Having been there before ourselves, we changed off, though for no good and sufficient reason. The next time we are passing this way we shall change back again to the smaller place.

A Monte Carlo Gendarme.

Memories of the days when Robert Louis Stevenson lived at Hyères, and his little villa, which to-day is a notable literary shrine (to us, at any rate), was the only reason for our stopping anyway—not being partisans of tea or golf. Hyères, on the whole, is the most unconvincing French (*sic*) resort that ever was, but its climate is mild and one can play golf, tennis, and croquet without going far afield, and that is why it has become popular with a certain class of homeopathic sportsmen and sportswomen from this side.

Cogolin, forty odd kilometers further on, is quaint and the center of a flourishing industry which makes corks for bottles from the bark of the *chêne-liège*, which is gathered in the neighborhood in vast quantities. The process is interesting, and the young girls who mostly occupy themselves with the various processes are of a specious beauty which defies the author of these lines to describe with full justice. The susceptible should come and see for themselves.

Sainte Tropez for *déjeuner* would have been better than Hyères, for the Hotel Sube makes a *bouillabaisse* that is almost the rival of that of Chabas at Martigues.

"A plat there is in France that's famous,"

sang the poet; and he sang with reason.

Sainte Tropez is another artists' colony, and its "Golfe" is marvelously beautiful, and its top-masted, latteen-rigged barques are like nothing so much as great white birds as they come winging their way home at sunset.

Menton as Seen from the Frontier of Italy.

Sainte Tropez faces north and gets the *mistral*, that dread north wind, with full force when it blows. On the opposite side of the gulf, but facing south, is Sainte Maxime, with a few hundred regular inhabitants and as many more living in the magnificently named Grand Hotel. We gave the town and its hotel the go-by, though the place itself is really delightful. Fréjus was more to our liking; there at the Hotel du Midi we were out of the resort sphere of influence, and ate good, wholesome country fare instead of imitation Paris *plats*.

Fréjus is the deadest town on the map of France, and we ourselves, just here, nearly came to being included in the same category by reason of having run full tilt into a chain which barred the road at a railway level-crossing between Sainte Maxime and Fréjus. It was not an effectual barrier, either, for we tore off the front lamps and one mudguard. One might well be half killed and his automobile entirely wrecked by such idiocy, and yet the train might come along and finish him off before he had time to pull himself together. Some day, after a few more accidents of a similar sort. these railway crossing chains will be plainly marked by a white placque hanging in the middle, or, indeed, they may be suppressed altogether. Meantime automobilists will do well to go slowly on this delightful shore road.

Fréjus is a quaint old relic of Roman days, with its ancient

The FRONTIER

The DOUANE

triumphal arch, its arena, and its aqueduct still tangibly in view —though all are in a shockingly ruinous state. It is for this reason that we love Fréjus more than we do its more highly polished little brother, Sainte Raphael, just beyond, on the shores of the Golfe de Fréjus, now a resort of the first rank—a decadent fall since the days when Alphonse Karr, Gounod, the musician, Hamon, the landscapist, and Fromentin sought to make of it, and keep it, simply a quiet, unobtrusive little retreat.

The road Italywards divides just beyond Fréjus, the main road mounting the inner flank of the Esterels, via Les Adrets and its still existing auberge and its memories of the brigands Robert Macaire and Gaspard de Besse.

Via Sainte Raphael and the now wide-famed Corniche d'Or, that realization of a benevolent project initiated by the Touring Club de France, one of the marvels of modern road making, the road ultimately arrives at Cannes in about the same distance as the inland route, say forty kilometers.

Where Lives M. Baliff of the Touring Club.

To-day the surface of this new-made road is excellent throughout as it twists and turns and rises and falls by the water's edge, hanging perilously here and there on a narrow shelf of rock of porphery red all the way to La Napoule, just before Cannes. M. Abel Baliff, the president of the Touring Club de France, lives midway along its length. Perhaps it is for this reason that the road is so well kept. We are thankful for such a treat, anyway, for it is the most delightful forty kilometers on earth.

Now commences the classic Riviera, a region we already knew of old, even in good old bicycle days. Its scenic charms are as great as ever; indeed, that strip of coast line from Cannes to Menton, by Monte Carlo's rock and on across the Italian frontier, is without doubt the world's most brilliant panorama.

Cannes, Nice and all the rest now string out for fifty-odd kilometers, a succession of gay playground cities, with all the distractions that pampered humanity can suggest.

In the cities and towns of the Riviera to-day all is as *bruyant* and encumbered as the Rue de la Paix of a mid-November afternoon, and the *corniche* road by the sea, from Nice to Monte Carlo, is now doubly dangerous with a double line of tram tracks and an endless procession of scorching automobiles.

By the "Grand Corniche," up around Mont Gros, the Observatoire, and the Col de Quatre Chemins, is the better route by far, and the view is quite as superb, with Eze and its olive trees and La Turbie and its great Augustan trophy—in memory of that noble Roman's victory over the peoples of Gaul in the foreground, and Monte Carlo, Cap Martin and Cap Ferrat stretching seaward in the background far below.

What hill-climbs there are hereabouts! But what gentle grades they have! No modern automobile will give even a gasp at them; one could mount to the skies on such easy rises as those which climb up out of Nice or Menton via Roquebrune.

After Fréjus we put in the night at Cannes, merely because we had some friends whom we wished to meet, and because the Hotel Beau Rivage had a most convenient garage, and because the hotel itself—though a resort establishment in every sense of the word—was one which catered for an exclusively French clientèle, and therefore omitted the eternal *omelette au jambon, bifteck* and boiled mutton from its menu. Did you ever remark the frequency with which the *plats* occur when you, a stranger, take your seat at a *petit table* in a hotel which serves one class of fare for its table d'hote and another for *"les étrangeurs"*?

Coming out from Cannes the next morning we ran over a sheep—which was "playing" in the public road with a dog. The dog escaped, but the sheep became mutton forthwith.

Goats Never Get in the Way.

In the Esterels there is a road repairer who is always accompanied by a pet goat, with a great brass collar and a bell hung around its neck. The goat never gets in the way of an onrushing automobile which is trying to hold on to its speed as long as possible on the coming rise. It stands simply to one side and eyes the passing crowd with a genuine and intent interest. Wonderful beasts, goats! But sheep and dogs and chickens and small children—they are not in the same class!

The gateways into Italy from Nice and Menton are either via the mountain road over the col de Tende, via Sospel and the Italian Custom House at San Dalmazo de Tende, or via the shore road through the Pont Sainte Louis—where the Italian Customs arrangements take place—and Vintimille.

We chose the latter route on this occasion because we were bound on an itinerary which proposed following the Italian coastline all along to Reggio, where we were to cross to Sicily.

Leaving Cannes or Nice en route for Italy one might plan to take his déjeuner at that little seashore restaurant called the "Roches-Rouges," on the lower road just beyond Menton, on Italian soil. We had planned to do this because of pleasant memories of a former repast. This little Franco-Italian restaurant is really very good, though unpretentious, and you will be regaled while eating by the music of a quintette of smiling Italians, and afterwards have your photograph taken and printed on a half a dozen post-cards—at a cost of three francs—and the loss of ten minutes' time. Quick work!

The Route d'Italie leaves French soil and enters the neutral ground of the Pont Sainte Louis—marked by a great white painted triangle on the face of the cliff above—just beyond Menton. A moment after it boldly circles the face of the Maritime Alps of Piedmont, and in another six kilometers plunges through a tunnel and enters Ventimiglia.

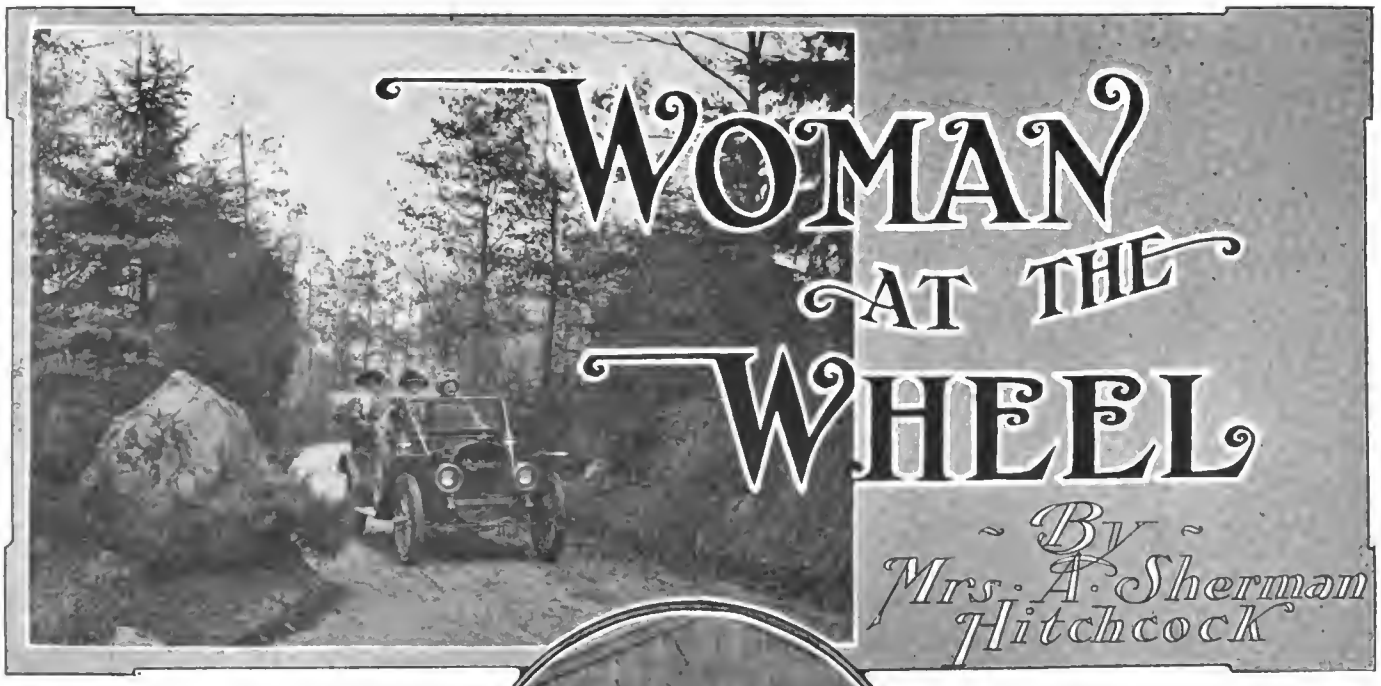
And One Passes from France into Italy.

The Montée Sainte Louis or Avenue de la Frontiere at Menton is well known of all automobilists bound into Italy. Here, at one end of the bridge, is the cabin of the French *douaniers,* where you present your "passavant," giving the details of your automobile in case you propose entering France again. At the other end is the Italian customs bureau, where, between sunrise and sunset, you may enter your automobile temporarily for three months into Italy upon the payment—in gold—(not even French or Italian banknotes being accepted) of two hundred francs for each five hundred kilos of weight. If you have that open sesame, the *triptych,* issued by the Touring Club de France or the allied automobile clubs, showing that you have already paid a similar sum into the coffers of that association, the procedure of passing the Italian frontier is but a matter of minutes instead of hours if you have not supplied yourself.

We, fortunately—for "time is money," as even the Frenchman has learned to say—were in the former class, but a poor unfortunate who followed in our wheel tracks had not taken the same precaution and was forced to weigh up his machine on the spot, calculate the tax, and then go back to the office of the Credit Lyonnais at Menton to change eight hundred francs worth of French banknotes into coin that would be acceptable to the Italian authorities—which he wasn't able to do after all, the bank having closed its doors for the day before he arrived.

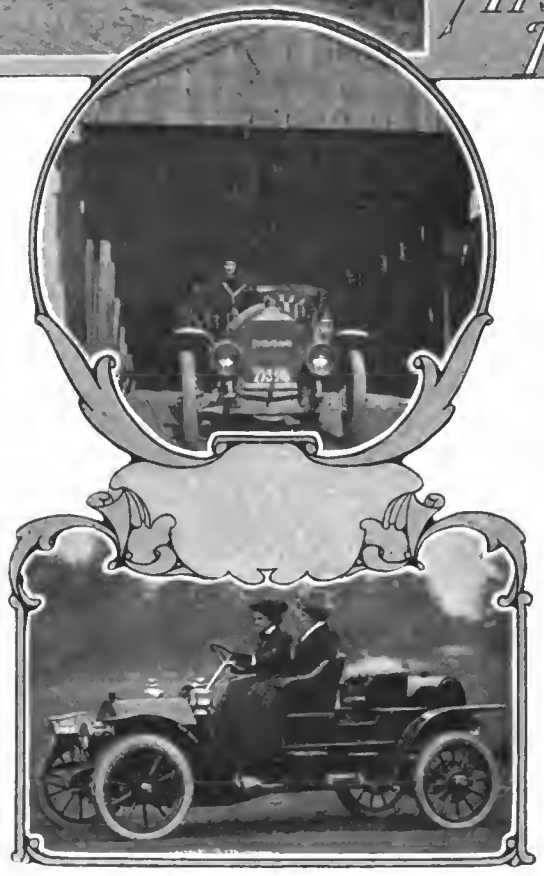
We all dined that night at the Hotel de Paris at San Remo (marked in the Annuaire de Route of the Automobile Club de France with a miniature knife and fork and a four-posted bed, indicating that food and lodging are good).

Our acquaintance of the road only arrived four hours after we did, however, and then only because he was able to bribe a customs official to change his notes into gold by the transferrence of a "Louis"—a ruinous piece of usury. Moral—go prepared!



WOMAN AT THE WHEEL

By Mrs. A. Sherman Hitchcock



WOMAN who has acquired the ability to drive her car successfully is now speeding over the country highways and through the city parks, while Woman who is a novice watches for her more competent sister with wonder—not unmixed with envy—and the desire is created to do likewise. The first time a woman operates her car without an expert to whom she can turn in a case of emergency she will have little confidence in her own ability, whether she has been taught by an experienced driver or otherwise.

Lack of Experience Leads to Confusion in Emergencies.—On each occasion when change of speed is necessary, when she has to avoid other vehicles and obstructions to her progress, it is exceedingly difficult for her to bear in mind even the most simple instructions. It is especially necessary at such times to have the car under complete control and to be possessed of presence of mind to do the right thing at the proper time. The ability to judge speed and distance and the knowledge of control are only to be obtained by actual experience; and careful study and keep observation, combined with intelligence, care and discretion, will in a short time give one complete confidence to drive a car with perfect safety. Until one has acquired confidence in herself it is very unwise to try to drive through congested thoroughfares, or in dangerous and out-of-the-way places.

Learning to Drive.—A clear road where there is plenty of room should be found for experimenting, and learning to steer properly should be the first thing attempted. The steering mechanism of a motor car will be found very sensitive to the woman beginner, the slightest turn of the wheel bringing an instant response that is rather confusing at first. The changing of gears should next be thoroughly learned, and to do this the best practice can be had by backing and turning around. This should be done repeatedly until there is an instinctive response to each condition. The woman motorist should avoid short turns until she has had sufficient practice to insure accuracy of control and judgment. After confidence has been fully established the operation of changing gears on a motor car becomes almost second nature.

Preparing the Car Before Starting Out.—The experienced driver will be able to detect any faults in the motor of the car she is driving and with the knowledge she should possess will usually be able to overcome the difficulty and thus prevent more serious trouble from arising. A woman autoist can never be too well informed regarding the mechanical features of her car, as she cannot always depend on others to help her out in case of trouble. Before starting out the tires should be examined to see whether they are in good condition and properly inflated and all the wearing parts of the car well oiled, particularly the steering pivots and joints of the steering gear and the change gear and brake mechanism. The crankcase, gearbox and differential case should be seen to have a sufficient supply of grease or oil and the gasoline, water and oil tanks should be filled. The batteries should also be tested before the start and the spark plugs examined to see if they are clean. A good rule for the autoist is to test the brakes daily, the operation only taking a second, but being of the utmost importance for safe driving. No trip should be taken without extra spark plugs and inner tubes, and an extra battery should be provided in case of failure of the regular one.

Strict Attention Must Be Paid to the Driving.—The most important thing to be remembered by the autoist is to keep her attention concentrated on the work before her. It is bad practice to look around, wave to one's friends or become so interested in conversation with one's companion that the responsibility is overlooked, as one is apt to lose control of the wheel, strike a sudden obstacle in the road and dash into a fence, river or sidewalk before it is possible to prevent it. In starting off from a standstill the low gear should always be used,

the change into higher gear being made as the car gathers speed. If starting is attempted on high gear the motor will be stalled, which necessitates getting out and cranking.

Changing Gears and Negotiating Corners.—In general in changing gear time should be taken; one should not attempt getting into the high gear until the speed of the car increases sufficiently and the motor is running strongly. In taking a hill the motor should be given plenty of gas and the car driven up on the high gear as far as possible, but as soon as the motor shows signs of slowing down the change should be made to a lower gear at once. Corners should be taken at a slow rate of speed and plenty of room allowed in case of skidding. The autoist should not take chances, as it is better to lose a little time in slowing up than risking injuring some one or the car. Bumps and cross-walks should be taken at an angle, as it tends to distribute the shock evenly, whereas, if one drives straight over them the whole brunt of the shock falls on the steering gear and front wheels and this in the long run will send the car to the repair shop. Car tracks should be taken at as near a right angle as possible for the same reason.

Precautions to Be Taken in City Streets.—When the autoist has acquired sufficient control of her car to drive on roads having considerable traffic she can next attempt driving on city streets. Here the greatest care must be exercised; turns must be made slowly and obstructions avoided by liberal margins. The autoist must be ready at any time to slacken speed when in doubt as to the course to be taken by other vehicles and equally ready to move ahead quickly when the occasion demands it. When leaving the car standing by the sidewalk or road the emergency brake should be set and the switch plug removed to prevent possible accidents through people meddling.

Motor Faults and Their Detection.—The detection of motor faults is by no means difficult and the majority of them are readily recognized. For instance, an explosion is heard in the muffler. This is caused by too much gas being fed to the motor, and as this gas cannot be fired or exploded it is forced into the muffler, where it is exploded by the heat of the exhaust. Blue smoke from the exhaust is a sign of too much lubrication, but black smoke shows that too much gasoline is being used in the mixture. If the motor slows down the fault will most likely be in the mixture or due to the battery being run down. If the motor stops suddenly the trouble can be attributed to an ignition fault. If it slows down and after a minute or two starts up again and runs for quite a while it is a sign that the battery is getting weak. Sometimes one cylinder will miss fire, and though the spark plug has been cleaned and examined and seems to spark well when the car is running on the level, it refuses to do duty on a hill being reached, it is a certain sign that the plug is short-circuiting. This may be due to dirt or oil on the inside or because the porcelain is cracked. The remedy is to change the plug for a new one.

When the Motor Overheats.—In the case of an empty water tank where the absence of water has not been discovered until the motor has overheated and the pistons seized, test the cylinders by sprinkling a few drops of water on them. If the water hisses and quickly evaporates do not refill until the motor cools off. Kerosene taken from the lamps can be poured into the cylinders—this can be done while they are hot. If the pistons have seized tightly the cooling process is a slow and tedious one. The careful driver will try to avoid this happening and will take prompt measures to overcome any symptoms of overheating, such as steam issuing from the filling nozzle or water coming out of the overflow pipe while driving. Other symptoms are continued firing after the ignition is switched off or a slight cloud of smoke rising from the motor.

When a Bearing Becomes Hot.—If a bearing should become hot the best and simplest way to cool it is to pour water on it until quite cool and then lubricate well before running again. In new cars the bearings are very apt to run hot. The least looseness in the bearings of a connecting rod or in the main shaft will set up a jarring knock or sound. This noise will speak plainly to an ear that has once recognized it, and if the motion that causes it is not immediately overcome it will prove most destructive. A common cause of loss of power in gasoline motors is poor compression. This may be due either to the piston rings failing to bear smoothly and evenly against the cylinder wall or to one of the valves, usually the exhaust, not closing tight, or not quickly enough.

THE AUTOMOBILE CALENDAR

AMERICAN.

Races, Hill Climbs, Etc.

May 7.....Birmingham, Ala., Track Race Meet, Police Relief Association.
May 10-13.....Detroit, Mich, Four-Day Endurance Run, Detroit Automobile Dealers' Association.
May 15.....Washington, D. C., Reliability Sealed Bonnet Contest, 170 miles, Westminster and return, Washington Automobile Club.
May 18-19.....Norristown, Pa., Second Annual Endurance Run, Norristown Automobile Club, to Hagerstown, Md.
May 22.....Hartford, Conn., 200-Mile Endurance Run, Hartford Automobile Club.
May 22.....Newark, N. J., Third Annual Endurance Contest, New Jersey Automobile and Motor Club, 190 Miles.
May 22.....Albany, N. Y., Hill Climb, Kenwood Hill, Albany Automobile Club.
May 28-30.....Denver, Col., Reliability Contest, Pueblo and return, Denver Motor Club.

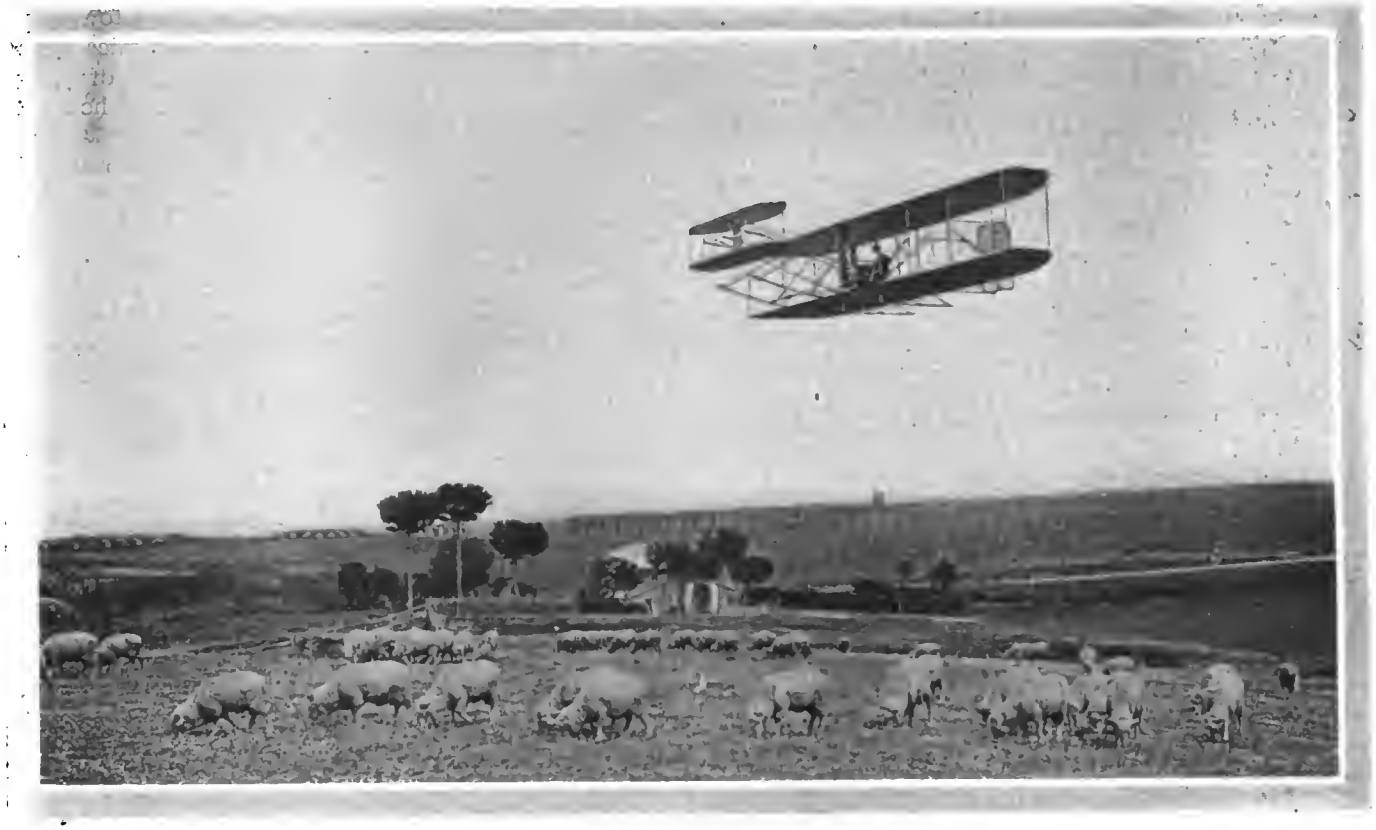
June 24-26.....Montreal, Blue Bonnets Track, Race Meet. R. M. Jaffray, Manager.
June 25-26.....Philadelphia, 24-Hour Track Race, Quaker City Motor Club.
July 3 and 5.....Wildwood, N. J., Straightaway Races, Motor Club of Wildwood.
July 4.....Los Angeles, Cal., Southern California Automobile Dealers' Association. Road Races, 250 Miles for Large Cars; 150 Miles for Light Cars.
July 12.....Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.
Sept. 6-11.....Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
Sept. 15.....Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Oct. 7.....Philadelphia, Second Annual Stock Chassis, 200-mile Race, Fairmount Park, Quaker City, M. C.
Dec. 29-30.....Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

FOREIGN.

Races, Hill Climbs, Etc.

May 6-9.....Austria, Small Vehicle Competition, Automobile Club of Austria.
May 8-23.....Belgium, Antwerp, Sixth International Automobile, Cycle, Maritime and Fluviatile Exposition.



Wilbur Wright Astounds the Romans of To-day by Traveling Over the Appian Way Built Before the Cæsars.

WRIGHT BROTHERS ARE COMING HOME.

LONDON, May 3.—Wilbur and Orville Wright are leaving for America, Thursday, their principal idea being the completion of the trials for the United States Government at Fort Myer, Va.

To-night there was a remarkable demonstration of enthusiasm at the Institute of Civil Engineers, when the Aeronautical Society of Great Britain conferred on the Wright brothers its first gold medal. Those who had gathered at the institution to witness the presentation cheered and applauded repeatedly, while the Wright brothers blushingly bore their honors through an hour of the warmest eulogies. Finally the entire assemblage rose up and gave three cheers for each of the brothers. They sang "For They Are Jolly Good Fellows," and ended by cheering Miss Katherine Wright. Sir Henry Maxim, Lieut. Col. Baden-Powell, Capt. F. S. Cody, an American, who is struggling, but thus far unsuccessfully, to perfect his own aeroplane for the British Army, and a large number of scientists and ladies were present.

Col. J. E. Capper, the War Office's aeronautical expert, referred to the Wright brothers as "unspoiled, as though they were nobodies," and declared that the nation which failed to keep pace with the flying developments might get badly left in war.

Both Wilbur and Orville Wright made speeches, tersely expressing their thanks. Earlier in the evening they were guests at a dinner at the Ritz Hotel, given by the Aeronautical Society.

The Wrights had a conference with War Secretary Haldane to-day, but the War Office is not likely to conclude arrangements with the inventors until their aeroplane has had a trial in England in the presence of experts. Their engagements in the United States and Germany, however, preclude the possibility of their being able to attend this personally for some months.

MAINE NOW HAS AN AIRSHIP COMPANY.

PORTLAND, ME., May 3.—That the men of the "Pine Tree" State are progressive is shown by the incorporation here of the Flying Auto Company, which will manufacture and sell aeroplanes and dirigible balloons. The capital stock under the terms of the incorporation is to be $1,000,000.

FIRST WRIGHT FLYER GOES TO MUSEUM.

PARIS, May 1.—After a short but glorious career, Wilbur Wright's aeroplane, the one which went through the French campaign of 1908 and showed the world that flight was a reality, is about to be put in the Arts et Metiers Museum in Paris. According to the contract passed between the Wright brothers and Lazare Weiller, the machine should become the property of the French committee on fulfillment of the contract. This has now been done; but the committee, having no practical use for the machine, has decided to present it to the Paris museum, where it will occupy a position by the side of Ader's Avion, the first flying machine in Europe to rise from the ground, with Cugnot's steamer, built in 1770, and considered the father of the modern automobile, as a very near neighbor.

The Wright machine thus secured for the Paris museum was brought into France last year at a time when only one other similar apparatus existed. The other one was then in the hands of Wilbur Wright, but was practically put out of commission in the unfortunate accident at Fort Meyer. Both machines had been entirely built by the two brothers, even the engine being their own handiwork. The Wright aeroplane made its first public appearance on the Hunaudieres racecourse near Le Mans, but after a few short distance flights was removed to the Camp d'Auvours, further out of town, where its last flight was the winning of the Michelin prize by a journey on the last day of the year, lasting nearly two hours.

Now Wilbur Wright is using a French-built machine—made of American wood—and even his motor has come from a French factory. Fifteen of his machines are in actual service and others are almost ready for launching. Thus it was possible to remove the most glorious of them all from the flying ground and place it on a pedestal in a crowded city museum.

Gross II, Germany's New Airship, is to be stationed either at Metz or Cologne, on the German-French frontier. The dirigible is driven by two eight-cylinder Koerting motors of 75-horsepower each.

ENDURANCE TESTS NOWADAYS.

Clean scores in profusion will not be features of the endurance runs and contests of the current season. Once it was undoubtedly necessary, in order to demonstrate to the general public the reliability of the motor-driven vehicle, to have events wherein the rules duplicated in some degree the actual touring conditions which a man might meet with in a cross-country run. But the buying public has come to realize that the average automobile answers satisfactorily to the needs of any reasonable owner, and hence, in order to make contests valuable and at the same time to retain general interest, the rules must be drafted in such manner as to call for a more rigorous scrutiny of the survivors than in previous years.

This doesn't mean, however, that all the glory goes to the car which evolves as the winner, for all others performing creditably and in excess of what is demanded by the amateur owner are certain to obtain a commensurate amount of publicity for participation. Of course, in the big, complicated and long-distance contests competitors are certain to be few unless they have resources tracing back to the factory itself. In events of a local character the tendency is toward contests wherein the real amateur can compete against his own kind, and thereby extract a profitable and pleasurable experience. Meeting with other fellow autoists he gains much from observation of their methods, and, furthermore, there is certain to be a greater spirit of helpfulness toward one another than is usually the case wherein trade interests somewhat interfere with candid expression of opinion and opportune aid in the way of suggesting how some remedy will meet the needs of the situation.

It is a difficut matter for the average onlooker to realize that things other than speed are involved in the running of a contest, and in consequence the repeated injunction of "Hit it up!" is certain to be heard for some time to come. The discriminating public, however, is beginning to learn that economy of operation and proven reliability are greater factors than speed in determining as to the car which best supplies all around utility.

True it is that there will be those who think that they must have excess speed, but the long distance traveler will continue to miss half of the delights of the healthful pastime in which he indulges in a swirl of dirt and leaves behind a trail of cuss words from those who consider him both partially insane and criminally inconsiderate of other users of the road.

* * *

NOW THE SLIDE VALVE ENGINE.

In the wake of the success of the British-Daimler slide valve engine, known as the Silent Knight, because of its American inventor, will doubtless come a number of motors along similar lines. This success was accentuated by the unusually severe tests to which the engine was subjected by the committee of the Royal Automobile Club.

The tests were such as very few makers of automobile engines would care to subject their products to, but in this case the Daimler company found it necessary to prove in an undoubted fashion the efficiency of their new motor. The discussion of this gained volume as time went by and no facts were forthcoming. Then it assumed the form of doubt and acrimonious reflections. Finally, the very life of the company being in jeopardy, in default of proof, the company decided to make a public trial that would prove once for all that their foster child was all that they had claimed for it.

The result of that trial is now well known, and with the publication of it the most carping of critics has become a rabid adherent. Any engine which can maintain for 132 hours a power output in excess of its rating, amounting to 42 per cent. of that rating, or that can maintain for five hours an output of 50 per cent. in excess, is good enough for anybody, regardless of principle or methods of construction.

If, in addition, a car equipped with the selfsame engine can run, immediately thereafter, a distance of nearly 2,000 miles on a basis of over 35 ton-miles per gallon—35.46 to be exact—it is then apparent that the engine is not only a good one, but a remarkably fine product and probably superior to many of the ordinary motors with mushroom valves.

This test and its unusual conclusion, without a particle of doubt, marks the beginning of an epoch in automobile engine design and construction—the slide valve epoch. While the engine of the automobile of to-day has improved in such marked degree that its earliest predecessor beside it looks like a bunch of junk, the final word has yet to be said, even though the improvement should be painstakingly gradual.

HOW NEW YORK OBTAINED A LIBERAL LAW

ALBANY, N. Y., May 3.—By the time this summary of what motor-vebicle legislation has been secured in New York this year is ready for issue, Governor Hughes may have signed the Hamn bill which outlines the new motor-vehicle law. Again, he may not, as the bill is among those the Governor may hold for 30 days. This bill embraces practically all there is to motor-vehicle legislation this year. In its Senate form it was killed by amendments in the Assembly, and was rescued in its Assembly form only the day before final adjournment. Its history is the story of the year on the subject.

It will be recalled that a year ago when the Legislature adjourned an agreement had been reached after several conferences and a bill introduced by Senator Armstrong and Assemblyman Hamn which contained no miles-per-hour clause and had an annual registration fee for autos. It did not pass, nor could the Governor be induced to recommend it for the extra session.

This year Senator Allds, who succeeded Senator Armstrong as the head of the finance committee, and Assemblyman Hamn reintroduced the old eleventh-hour bill of 1908 very early in the session. But nothing was done for three months. In fact, it became the policy of the autoists to press no sort of legislation of a general character, but to wait and ascertain what the Legislature was to do with Governor Hughes' recommendation that the registration fees on autos should be increased so as to provide a respectable fund for the repair of the improved highways of the State.

There was the usual grist of freak, hostile and restrictive legislation introduced, but the legislative leaders in both houses put a crimp in it from the start, and no committee reported a bill or bothered anyone with hearings on the bills.

Finally there was a conference called by the legislators at which the New York State Automobile Association, backed by the A. A. A. and the N. A. A. M.; and the A. C. A. and a few others, met and agreed without much difficulty on a bill which repealed the old motor vehicle law and substituted a new and revised motor vehicle regulation code, the chief feature of which was the abolition of the speed limit provisions of the old law and the substitution of a fair and equitable proposition putting motor-driven vehicles on the same basis as other users of the highways. Another feature was making horsepower the basis of tax or license fees and taxing the autoist for his registration certificate and number $4 a year for machines of less than 20 horsepower; $6 for those less than 30 horsepower, and $10 for all over 30 horsepower.

There were other new features, such as a licensing of professional chauffeurs and the issuance of different colored badges each year; the prohibition of permanent anti-skidding devices on wheels; the establishment of a $50 fine penalty, which is the limit of the jurisdiction of the country justice, thus taking out the absurdity of the old law where a fine of $100 and more was decreed, notwithstanding no justice in the rural districts could constitutionally impose a fine of over $50. There was at first a $2 fee for chauffeurs on commercial vehicles, but as this created classes it was deemed unconstitutional and dropped, the final draft of the bill making the chauffeur's fee flat at $5.

When the bill was first printed it left the enforcement through the collection of registration or license fees and badge or certificate issuing to the Secretary of State. Samuel Koenig, a Republican State committeeman, occupies that office now. He went to the legislative leaders before the bill passed the Senate and demanded more money to run that bureau in his office. Senator Allds, as head of the financial committee of the Senate and also introducer of the motor-vehicle law, did not coincide, and when the Secretary of State made the bluff that he did not want the bother of the auto tax collection, Allds prompty amended the bill to give the whole business to the State Highway Commission (where it properly belongs, as the motor-vehicle law is to be a section of the State highway law and was so passed). The bill passed in that shape under an emergency message from Governor Hughes, who was undeniably interested in its passage.

Then Koenig got busy with the Assembly. Assemblyman Hamn did not amend his bill as he was supposed to do and exclude the Secretary of State. He left it in the rules committee, and Senator Allds' bill was reported out. On the floor of the Assembly the next day Secretary of State Koenig's friends joined with the rabid, rural anti-auto Legislators for two things: to either change the Allds bill to put the collection of fees in the Secretary of State's office and cut out the State Highway Commission or to emasculate the bill and let it die.

Assemblyman Howard, of Tioga, who wanted a speed limit, the making of all regulations by villages, towns or cities without reference to what other regulations were made, and a higher tax, put bis amendments up, and on a rising vote they were carried and put in the bill. That killed the Allds bill so long as the amendments remained in it. It could not be printed in time to pass regularly, and none would ask the Governor for an emergency message, and the autoists would not vote for the bill anyway while in tbat shape. The same night there was a conference with Sam Koenig, and on condition that the Hamn bill —identical with the Allds bill just amended save that it retained the Secretary of State as the fee collector—be passed the Koenig squad was called off from the opposition forces. As a further compromise and sop to the rural anti-auto legislators, the speed section was amended to take in the Connecticut law, making 30 miles an hour presumptive evidence of reckless driving when something happens. The "rules of the road" unintentionally omitted in the Senate bill were also put in. This and a few verbal amendments were all the changes in the bill, and thus the measure was practically what had been agreed upon before the bill started in the Senate.

This was passed in both houses the same day, and is now before Governor Hughes for his signature. It is the broadest gauge motor-vehicle law on any statute book, and purposely continues to omit that petty retaliation clause, which some autoists desire to have in, requiring every auto owner from another State where New York's license certificates are not recognized to take out a license here.

What takes the place of the old speed limit is section 287, and as amended in the Assembly when passed, reads thus:

"Every person operating a motor vehicle on the public highways of this State shall drive the same in a careful and prudent manner and at a rate of speed so as not to endanger the property of another or the life or limb of any person; provided that a rate of speed in excess of 30 miles an hour shall be presumptive evidence of reckless driving."

The rules of the road, to turn to the right when meeting and to the left when overtaking and passing, etc., are now in the bill to be a part of the highway law.

The Hill-Robinson bill to make joy riding a penal offense punishable as larceny went through, and to the Governor as a code amendment. It is provided for in the new motor-vehicle law, where both joy riding and malicious tampering with an auto is made a misdemeanor, and the chauffeur or other person may be fined $100 for doing it and sent to jail for six months and may also be suspended from privilege of operating an auto, if a chauffeur.

Secretary of State Koenig a few minutes after the Hamn automobile bill was passed, received a letter from William H. Hotchkiss, State Superintendent of Insurance, applying for license 1 under the new law. This is the first application received by Mr. Koenig. Superintendent Hotchkiss gave a full description of his touring car, his home address as 20 Lincoln parkway, Buffalo, and said that as soon as the blanks are issued he will be pleased to send in $10 for license No. 1.

STUDEBAKER PURCHASES CONTROL OF E-M-F COMPANY

DETROIT, May 3.—One of the most interesting deals with which the automobile world has ever been acquainted was consummated here Saturday when William E. Metzger, B. F. Everett and William Kelly transferred their interests, aggregating about one-third, in the stock of the Everett-Metzger-Flanders Company to the Studebaker Automobile Company, of Cleveland. The change involves a complete reorganization of the Everett-Metzger-Flanders Company, W. E. Flanders becoming president and general manager, C. L. Palms and Dr. J. B. Book remain on the directorate, and the new stockholders will secure two directors, one of whom will be Hayden Eames, of Cleveland, and the other Fred. S. Fish, general manager of the Studebaker Wagon Company, of South Bend, Ind.

Not the least important feature in connection with the deal, both to this city and the trade at large, is the entrance of the Studebakers into the automobile field on a scale in keeping with their operations in the vehicle line. Studebaker cars are well and favorably known, but this places the concern in the forefront in the medium-priced field that bas already proved so profitable. The Studebaker Automobile Company, which is under their direct control, will after September 1 next become sole distributors of the E-M-F. "Thirty" cars.

The price paid by the Studebaker Automobile Company for the Metzger-Everett-Kelly stock is not made public, but it is known to have been between $700,000 and $800,000. This furnishes some interesting information regarding E-M-F affairs. The company was organized eight months ago, succeeding the old Wayne Automobile Company. Its capitalization was $1,000,000, of which Metzger and Everett held one-third, Kelly's interest being about $75,000. In the transfer just made the two former are known to have received approximately $4 for every dollar of money they had invested.

That tbe price paid by the Studebaker company was not exorbitant, but that, on the other hand, it must be regarded as a gilt-edged investment is shown by the fact that during the eight months it has been in existence the net earnings of the E-M-F company have been $800,000. Not only this, the business is exceeding all expectations, the daily output of "Thirties" now being between 65 and 70.

The success of the concern is directly attributable to the efforts of two men—W. E. Flanders and E. LeRoy Pelletier. Flanders is recognized as one of the foremost factory men in the automobile world, and tbe fact that the E-M-F company will produce 7,500 cars this season reveals his ability in this direction in an unmistakable manner. Pelletier, whose fertile brain is responsible for tons of bright "copy," has made the E-M-F "Thirty" famous throughout the land. The change will in no way affect him, as he will remain as advertising manager of the reorganized company.

It is rumored that James Heaslett, formerly with the E-M-F company, will be made chief engineer, taking the post Mr. Kelly occupied. Mr. Heaslett is well known to the trade, having been identified with the Rainier and other companies as engineer. He designed practically all the Studebaker cars. Messrs. Metzger and Everett have not determined what they will do in the future. Both will spend some months traveling in Europe, takin life easy until next Fall, when there are intimations that they will once more enter the automobile field.

"OVERLAND" NEWS FROM TOLEDO.

TOLEDO, O., May 3.—The Kinsey Manufacturing Company, of Dayton, will move to this city about the first of July, and after that date will be maintained as a subsidiary concern to the Overland Automobile Company. The Kinsey Manufacturing Company is a large manufacturer of automobile parts, the principal portion of its output having been absorbed to date by the Stoddard-Dayton and the Overland companies.

Isaac Kinsey, principal owner of the concern, has sold his interests in the Dayton plant to the Dayton Motor Car Company, which will continue manufacturing automobile parts on a reduced scale, while the company proper will be removed to Toledo. This procedure was followed that the company's name might be transferred to the business in this city.

That Hitch in Pope Sale to Overland.

A temporary hitch has been experienced in the transfer of the Pope Motor Car Company's plant to the Overland Automobile Company. When the local concern built several additional buildings some years ago they were located on some of the city's property, which consisted of an unopened street. Now, in negotiating for the sale of its property, the Popes are unable to give a clear title, and the purchasers desire a bond insuring them from any trouble, a thing which the Popes will not agree to do. It is likely, however, that the city will vacate the street and give a good title, as the street is only 600 feet long and is in a part of the city which will never allow its being needed.

CARRIAGE CO. TO BUILD AUTO WHEELS.

The Shortsville Wheel Company, of Shortsville, N. Y., is preparing to go into the manufacture of automobile wheels, in addition to continuing its manufacture of carriage wheels, and has purchased a complete outfit of machinery for the purpose from the Defiance Machine Company, Defiance, O. The new department is to be entirely separate from the carriage wheel plant, and it is expected that a new factory will be erected in the Fall.

NIEUPORT MAGNETO WORKS FOR DETROIT.

DETROIT, May 3.—While complete details are lacking, it is known positively that the Nieuport Magneto Company, makers of the famous French magneto, will in the near future establish an American branch in Detroit. The men interested in the enterprise have been looking over American territory for some time with a view to selecting a location for a plant. The clinching argument was supplied when a local automobile manufacturer expressed his willingness to contract for a large number of Nieuport magnetos, provided they were manufactured here.

Whether the company will manufacture magnetos in their entirety at the outset, or import the parts and have the assembling done on this side, depends largely on the success met with in securing a sufficient number of skilled employees. However, it is the intention to ultimately build a plant that will furnish employment to several hundred persons, next year's output of magnetos being placed at 25,000. French capital will, it is understood, hold a controlling interest of 51 per cent., the rest of the capital being supplied by Americans.

Zeglen May Locate in Detroit.

Detroit also may shortly number among its industries a factory devoted to the manufacture of a puncture-proof and impermeable automobile tire. C. Zeglen, of Chicago, has been here for some days looking for a site for a factory for the manufacture of auto tires that will employ in the neighborhood of 2,000 persons. Zeglen is maker of a bullet-proof cloth, and controls patents for a puncture-proof tire composition.

YORK ALSO MAKES ITS ENGINES.

YORK, PA., May 3.—The York Motor Car Company desires to have it unmistakably known that in addition to the manufacturing of its parts, it also makes its own engines. An article in THE AUTOMOBILE of recent date excepted the engines, and the York company desires to have the fact known that such is not the case, for it particularly prides itself upon the motor of the car.

General Managers Miles and Reeves Were Treated to a Tour of Fulton County and Were Guests at a Fried Chicken Supper.

MILES AND REEVES FIND FOR ATLANTA SHOW

ATLANTA, GA., May 1.—When S. A. Miles and Alfred Reeves, heads of the two big national associations of automobile manufacturers, returned to New York last night they had tentatively announced the dates of Atlanta's first show as November 27 to December 4, and also had made careful plans for the arrangement of exhibits in the big new Auditorium-Armory.

Atlanta's show has been in the air now only a few months. It was proposed by Atlanta's newspapers and worked up by the Atlanta Auto Trades Association, an organization formed for that very purpose; the Fulton County Automobile Club, and the Atlanta Chamber of Commerce. A few months ago delegates from these bodies went to New York and won over the joint approval of the big manufacturing associations.

This visit to Atlanta of the representatives of these organizations was the result, and the city spread itself to give the delegates a good impression. There were meetings with the Atlanta organizations interested, a careful inspection of the Auditorium-Armory, a tour of Fulton County in a fleet of Whites, and a regular "fried chicken supper" at the Fulton County Automobile Club's new house.

It was at the meeting of the directors of the Chamber of Commerce at which the show proposition was definitely completed. Those present, besides Messrs. Miles and Reeves, were:

President Candler, President Edward Inman, of the Automobile Club of Fulton County; E. W. Gans, president of the Atlanta Auto Trades Association; Major John S. Cohen and Clark Howell, of the Atlanta committee, who went on to New York and secured the show; S. E. Davidson, Frank Weldon, Frank S. Ellis, Rawson Collier, Asa G. Candler, Jr., Beaumont Davison, F. L. Seely, F. J. Paxon, D. Woodward, V. H. Kreigshaber, Mell R. Wilkinson, H. A. Maier and Secretary Walter G. Cooper, of the Atlanta Chamber of Commerce. The contract as drawn up between the Atlanta committee and the National Association of Automobile Manufacturers was read, and the Chamber of Commerce gave its unanimous sanction and approval.

Clark Howell, at the request of the meeting, outlined the preliminary steps which led up to securing the sanction of the two automobile associations upon the Atlanta show, and secured an agreement whereby the two associations which hold shows at different times and in different buildings in New York City each year will work together in the Atlanta show just as they have done heretofore only in Chicago.

A New York-Atlanta reliability run has been scheduled to precede the opening of the show, the New York *Herald* and Atlanta *Journal* being the most energetic in the project.

The Auditorium-Armory in which the first big show in the South will be held is a by-product of an effort to have an exposition in Atlanta in 1910. About $250,000 was raised for this purpose, but that was not considered enough to give a suitable "world's fair," and the men who had subscribed the money agreed to lend it to the city of Atlanta for the purpose of building an auditorium. The city agreed to pay back something like a third of the amount this year and gave it as an opinion that future administrations would pay back the remainder in smaller installments. The men who had put up the money agreed to take the chance, and the building was constructed. Committees of citizens and the architects examined every big auditorium in the country, spending weeks of time and thousands of dollars before they decided on plans. The result is a building which is as admirably suited for an auto show as it is for other purposes.

GEORGIA WANTS MORE AUTO RACING.

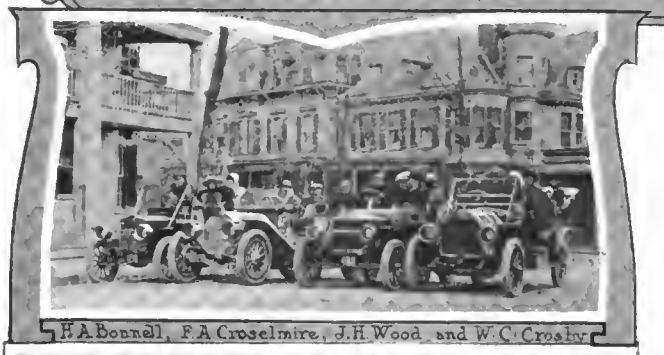
SAVANNAH, GA., May 3.—The three-day race carnival which is to be held in Fitzgerald, Ga., June 15, 16 and 17 is attracting wide attention just now in the automobile world. The course will be guarded by the State troops just as the Grand Prize race was in Savannah, and the races that are to be run are promised to be the best the South has had since the Grand Prize race.

If nothing about the Grand Prize race is heard from the Automobile Club of America in a very short time, steps will be taken by the Savannah Automobile Club to secure a race. It has been said that many of the members of the Savannah club are in favor of having their own cup, and if nothing develops it is probable that this will be done.

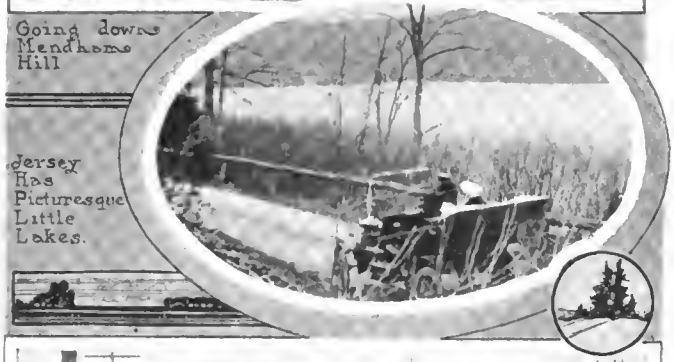
HARTFORD DEALERS RE-ELECT OFFICERS.

HARTFORD, CONN., May 3.—At the annual meeting of the Hartford Automobile Dealers' Association the following officers were re-elected: President, Ralph D. Britton; vice-president, Louis H. Elmer; secretary, S. A. Miner. The association already has plans under way to the 1910 show, which is to be held the second week in February. The following show committee was appointed: T. Dudley Riggs, chairman; B. F. Smith and R. D. Britton. Mr. Riggs resigned as chairman, and B. F. Smith was substituted. A uniform schedule for care and storage of cars was adopted, as follows: Storage for touring cars by the month will be $20, and $15 for runabouts. This price, it is announced, also includes washing and polishing of cars.

REAL ROADS AND SCENIC BEAUTY FOR JERSEY ENDURANCE RUN



H. A. Bonnell, F. A. Croselmire, J. H. Wood and W. C. Crosby.



New Jersey still building roads; near Cranbury Lake.

NEWARK, N. J., May 3.—Arrangements are practically complete for the amateur enduranee run of the New Jersey Automobile and Motor Club, scheduled for May 22, over a 95-mile circuit, which will be twice covered, thus giving a total distanee of 190 miles.

Of eourse the start will be from Newark, and Hackettstown, 42 1-2 miles exactly half way, will be the only other checking place. The route includes some of New Jersey's best roads and most picturesque scenery, but there are some stretches of highway which could be improved upon.

To Hackettstown the course is one long ribbon of macadam, with the exception of Schooleys. Then comes the run through the prettiest section of country touched by the tour, near Tranquility. Beyond there will come the crucial test. If it is rainy during the run, or just preceding it, the drivers will have their hands full in reaching Stanhope with clean cars or clean scores; if it is dry and the weather is fine, they will eneounter roads that are not macadam and which in some parts may be partially blocked by road repairing operations, but nothing that should hamper them seriously. It may be a bit hard on tires, but otherwise will cause little trouble.

Recently the committee in charge of the contest, H. A. Bonnell, chairman; F. A. Croselmire, A. D. Le Messena and H. A. Bowman, made a second tour of the circuit and found the route in better condition than on the original journey, some three weeks before.

The matter of observers has been satisfactorily settled by arranging to have students in the graduating class at Stevens Institute of Technology at Hoboken act in the capacity of officials. These men all have had an engineering training and know the difference between a spark plug and an inner tube. Most of those who will act have expressed a desire to stay on duty for the entire ten hours. No man will be allowed to stay on the same car for the complete run, however, but each will be shifted to another car when he reaches Newark at the end of the first lap, at about 1 o'clock.

CONNECTICUT DOESN'T WANT COMMISSIONER.

HARTFORD, CONN., May 3.—That pressure brought to bear from all quarters of the State to suppress the proposed bill for the creation of the office of eommissioner of motor vehicles was successful is evident from the fact that the scheme has been practically abandoned, at least as originally outlined. There was much opposition to the proposed measure, and various officials of the Connecticut Automobile Association, of which W. F. Fuller, of Hartford, is president, were at odds over the matter, one faction being for and another against the proposed bill. Senator J. W. Alsop, Senate chairman of the committee on roads, rivers and bridges, made a motion in the Senate that this bill, together with the proposed amendment to the motor vehicle law proper, be recommitted to the committee. It is the intention of this eommittee to redraft the measures and make such changes as are deemed necessary. In the motor commission bill the committee has decided not to recommend the appointment of a commissioner at a salary of $2,500, but instead to leave the enforcement of the law with the secretary of state (which is the present arrangement), and to provide for the appointment of a "supervisor of motor vehicles" at a salary of $2,000 per year. The term of office is to be for four years, and appointment will be by the secretary of state, who shall also have the power to summon witnesses to hearings on complaints. The new bill does not clip the wings of the seeretary of state, so to speak, as did the original proposed measure, much to the satisfaction of the opposition contingent regarding the original bill.

Aviation Grounds on Motor Parkway.—The meadow opposite the grand stand of the Long Island Motor Parkway has been made the official aviation ground of the Aero Club of America, according to President Cortland Field Bishop. Rights have been acquired for the ereetion of the necessary buildings. The Automobile Club of Ameriea will direct and control all aviation contests and have custody of the prizes, under authority of the International Aeronautic Federation.

What the Clubs are Doing These Days

A. C. OF PHILADELPHIA NOW HAS 740 MEMBERS.

PHILADELPHIA, May 3.—For the convenience of its rapidly growing membership the Automobile Club of Philadelphia has been compelled to establish easily accessible quarters on the ground floor of the Hotel Windermere, at the northwest corner of Broad and Locust streets, diagonally across from the Hotel Walton, where the Quaker City Motor Club holds forth. A suite of three rooms has been secured, consisting of assembly, reading and map rooms, where members will find all the necessary maps and data for laying out tours, etc. By an arrangement with the hotel management, the club has the benefit of most of the facilities afforded by a separate club house—restaurant, baths, barber shop, bar, cigar stand, etc., being located on the same floor with the A. C. of Philadelphia suite.

The club charter has been so amended as to permit of an increase in the number of directors to not less than nine nor more than twelve, the terms of office of one-third to expire each year. A limit of 1,000 has been placed upon the membership, and the maps, routes and signs committee and the touring information committee have been combined under the chairmanship of W. O. Griffith. Arrangements have been made whereby members of the club can secure fire and liability insurance, or either, at lower rates than when applying personally. Sixty-six new members were admitted at the last board meeting, and the total on the rolls is now 740 in good standing.

ACROSS PENNSYLVANIA AND RETURN RUN.

PHILADELPHIA, May 3.—After looking up the numerous routes for crossing the State, the Quaker City Motor Club has determined upon the one to be taken in its June run to the Smoky City and return. Starting June 14, the contestants will follow the usual route to Reading and will then leave the Harrisburg route and strike northwest to Pottsville, Bloomsburg and Williamsport, where the night stop will be made, a distance of 180 miles. From Williamsport to Johnstown, 143 miles, will be the course on the next day, through Lock Haven, where all the paper for government money is made, Tyrone, and Altoona. Mountain climbing will be a feature throughout the second and third days of the contest.

Pittsburg is merely touched on the third day, leaving Johnstown in the morning and traveling 72 miles for lunch, through Blairsville and Wilkinsburg. Turning eastward again in the afternoon, the roads through Greensburg, Holidaysburg, Huntington and Reedville to Lewiston will be taken, 93 miles, making the distance for the day 165. Philadelphia is about that same distance from the night control, and will be reached over the route through Harrisburg and Lancaster. The entire trip will be about 725 miles in length.

PRICE CLASSIFICATION FOR SPORT HILL CLIMB.

BRIDGEPORT, CONN., May 3.—The climb of Sport Hill this year will be conducted by the Automobile Club of Bridgeport under the price classification recently announced by the A. A. A. This was decided upon at a recent club meeting and is one of the last matters to be definitely arranged. The climb will be held May 31, and will include nine classes. President Frank T. Staples has offered a handsome silver trophy for amateur driver, and the Board of Trade trophy and the one given by the Isotta Import Company, of New York, will again be open to competition. State troops will patrol the course and A. L. Riker will again act as referee. Entry blanks are now ready and may be secured from Ralph M. Sperry, Box 518, Bridgeport, Conn.

IOWA AUTOISTS STRENGTHENING STATE BODY.

MARSHALLTON, IOWA, May 3.—With the election of the Iowa State Automobile Association to membership in the A. A. A., the work of further organization of automobilists in the cities of Iowa is rapidly progressing. The charter members were the clubs of Council Bluffs, Marshalltown, Mason City and Sioux City, these incorporating the State body soon after forming it. Five other cities are now interested in the work, Dubuque, Davenport, Cedar Rapids, Boone and Fort Dodge.

The officers of the association are: President, Dr. T. B. Lacey, Council Bluffs; first vice-president, H. B. Groves, Sioux City; second vice-president, A. J. Zingre, Mason City; secretary, D. J. Denmead, Marshalltown; treasurer, W. H. Hanthorn, Mason City. These with J. L. Denmead, of Marshalltown, constitute the board of directors.

CROSBY PRESIDENT OF JERSEY'S BIGGEST CLUB.

NEWARK, N. J., May 3.—Without an opposition ticket, the annual election of the New Jersey Automobile and Motor Club was held to-night. These are the new officers selected: President, W. Clive Crosby; vice-president, Clarence H. Bissell; secretary, A. B. Le Massena; treasurer, George H. Simonds; trustees, H. D. Bowman, Jay L. Adams, Jr., and Paul E. Heller.

The new president of the organization is also president of the Associated Automobile Clubs of New Jersey. Reports of officers showed that the club has a membership of more than 1,500 and is the second largest in that regard in the A. A. A.

KNOXVILLE AUTOISTS FORM A CLUB.

KNOXVILLE, TENN., May 3.—Automobile interests in this city have been focused through the organization of a local automobile club. About twenty-five autoists met recently and elected the following officers: President, W. J. Oliver; vice-president, N. E. Logan; secretary, E. G. Oates; treasurer, U. D. Beeler. Several matters will receive the attention of the body, among them being the local speed regulation, the improvement of good roads around the city and the development of sport. There are no mountains which would give a chance for a climb similar to that of the Lookout Club at Chattanooga, but the pikes would be suitable for speed events.

BALTIMORE'S ORPHANS TO BE ENTERTAINED.

BALTIMORE, May 2.—The committee of the Automobile Club of Maryland in charge of the Orphans' Day outing, June 9, is arranging to make this event by far the best ever held. At least 500 children will be cared for this year, and the committee has assurances of enough cars for the purpose. The start will be from the center of the city, through Druid Hill Park to Electric Park, where the orphans will have refreshments and be the guests at an entertainment. The outing committee comprises E. A. Dolle, chairman; Dr. H. M. Rowe, Frank W. Darling, C. Howard Milliken, J. M. Zamoiski and James S. Reese.

MONTREAL CLUB SECURES OILED ROADS.

MONTREAL, May 3.—Co-operation between the Automobile Club of Canada and municipal authorities has resulted in the decision of the latter to have the city road department oil Park avenue, from Pine to Mount Royal avenues, in order to prevent dust. A combination of oil and coal tar will be used, and it is hoped that adjoining cities and country officials will see the advantage of the plan and do likewise.

Alco Tourabout Fitted with Special Alco Top.

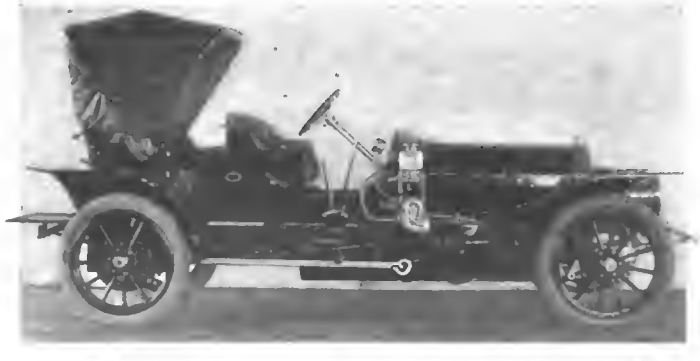
HOW A NEW SPARK PLUG WAS INTRODUCED.

In this era of modern advertising the marketing of a new product is not only unique and successful, but the campaign is often wonderful in its results. This is true of the plans carried out in the introduction of the Red Head spark plugs by the Emil Grossman Company, of New York, and shortly to be reproduced in bringing public attention to the hydraulic windshields made by the same concern.

In the latter part of February the campaign was started through the use of considerable advertising space in THE AUTOMOBILE, *Motor Age* and one other paper, just mentioning the name "Red Head," followed by another series stating, "Red Head Is Coming," "What Is Red Head"? and "Everybody Is Talking About Red Head." The advertisements of small size each were sprinkled through the papers, and March 4, inauguration day, the Red Head spark plug was announced in double-page advertisements printed in colors, while in the same issue appeared a number of small cards using the words, "Red Head Is Here." On that day Mr. Grossman, who was in Chicago, sent out 550 telegrams to dealers calling attention to the advertisement in the various papers.

This first public announcement March 4 was followed by the first delivery March 16 by the manufacturers and in the issues of April 15, just one month later, there appeared a full page giving the names of 56 leading supply houses in 25 States which were then carrying in stock a full line of these plugs, covering the United States and Mexico from the Atlantic to the Pacific and from Maine and Oregon to the Gulf. Moreover, the number is increasing daily and demands became so urgent that the concern was influenced to insert an advertisement of a different character as early as April 1, which said: "Have a little patience! Red Head spark plugs are coming through as fast as human hands and improved machinery can make them." The advertisements, as a rule, are composed simply of a picture of the plug with the trademark prominent and little wording, only a few of the displays making comment on the features of the plug, the mere appearance seeming to bring orders from dealers, jobbers, and many automobile manufacturers.

After the first popularity was indicated from the results attained by the use of THE AUTOMOBILE, *Motor Age* and another publication, Mr. Grossman determined to attempt still another type of exploitation: that of supplying manufacturers, dealers and users with sample plugs with the proviso that they must be given a hard test and then the results made known. Consequently every dealer was supplied with an order blank in duplicate authorizing the delivery to them of two spark plugs each from any jobber and 15,000 plugs were thus distributed. At approximately the same time the manufacturers' interest was secured through offers to furnish them any number of Red Head plugs between 2 and 100 to be used by testers and reckless drivers with orders to resort to any means that "puts other plugs 'out of business'" and to note the result upon the Red Head. A campaign to the owners is being planned.



Six-Cylinder 48-Horsepower Pierce Arrow Miniature Tonneau.

DETROIT HAS DELAYED IN TAXICABS.

DETROIT, May 3.—The old horse-drawn coaches and omnibuses that have for so long been a familiar sight to travelers stopping in Detroit, will be supplanted in a large measure by taxicabs in the near future. The Detroit Omnibus Lines Company, holding the contract rights for transferring travelers between railroad stations and steamboat landings, and also maintaining carriage stands about the city, has made arrangements with the Detroit Taxicab Company to place 75 taxis in commission.

Agent Evans' Frontenac with the Oldest Automobilist.

In the automobile carnival parade of Monday in New York City J. J. Evans, general agent for Frontenac cars, had as a passenger, Mrs. F. D. Cottle, who was 100 years old on March 12, 1909. She occupied the rear seat to the left of Mrs. Evans.

WHAT PART IS THE STRONGEST?

In the majority of cases where an automobile owner is asked as to his idea of the strongest part of an automobile he will mention such parts as the piston wrist-pin, the crankshaft, gears or driving axle. There is a great strain on these parts, to be sure, but when the question arose recently in the Pierce-Arrow Motor Car Company's factory it was settled, according to an official of the company, by going to the testing laboratory, where records are kept of the strength of the component parts entering into cars. The engineer in charge stated that the valve springs show the greatest tensile strength, reaching 272,211 pounds to the square inch in tests. The nearest to it was a French steel which tested 237,787 pounds.

RIDER-LEWIS COMPANY IS INCORPORATED.

MUNCIE, IND., May 3.—Articles of incorporation have been filed with the county recorder by the Rider-Lewis Motor Car Company, of Anderson, Ind. The capital stock is $400,000, of which $50,000 is preferred. The directors for the first year are: Clermont Rider, Muncie; George D. Rider, Kentland; Ralph C. Lewis, J. W. Lovett, Anderson; Arsomas Burkdoll, Chicago; H. D. Lingle, Denver, and C. A. Ulsh, Rising Sun. The factory is being built in Anderson and will manufacture automobiles, cars, trucks, buggies and all kinds of motor-driven vehicles.

A Typical Frontiersman. Mr. Guggenheim Greets the Pathfinder in Wyoming. Miller Meets Acquaintances.

A STATEMENT FROM THE M. C. A.

By order of the advisory committee of the Manufacturers' Contest Association, a press notice was issued April 29 under the heading of "M. C. A. Corrects a Misstatement." Herewith is the material:

A statement has been issued to the daily press by the promoters of the New York to Seattle contest, specifically stating that the rules of the contest have undergone certain changes "pursuant to the recommendations made by the Manufacturers' Contest Association at their meeting of April 6."

This statement is misleading and without foundation. The Manufacturers' Contest Association did not hold a meeting on April 6, nor has it officially made any recommendations whatever respecting a change in the rules governing this contest. At its only meeting held March 30, the members declined by resolution to support the Seattle contest for stated reasons.

The promoters have very sensibly undertaken to correct many of the objectionable portions of their rules, but are entirely without authority to make a public statement that the changes have been made at the recommendation of the M. C. A., for that organization has within a week by mail vote declined to re-open the subject of the New York-Seattle contest, having already officially disposed of it.

By order of Advisory Committee,
MANUFACTURERS' CONTEST ASSOCIATION.

It is understood that several M. C. A. members were not unfavorable to the event under revised rules, but they have accepted without comment the decision of the majority.

A STATEMENT FROM THE PROMOTORS.

From Mills & Moore, the Eastern representatives, comes a press notice, released May 3, wherein is reaffirmed a claim of 13 entries made with 11 having paid the fee. The notice reads:

Some doubt has been caused in the public mind as to the attitude of the Automobile Club of America, in view of the activities of certain opponents to the Ocean-to-Ocean Contest. Chairman Robert Lee Morrell of the Contest Committee was asked as to the result of the letters reported to have been sent by the manufacturers to the president of the A. C. A., requesting that the club's sanction be withdrawn.

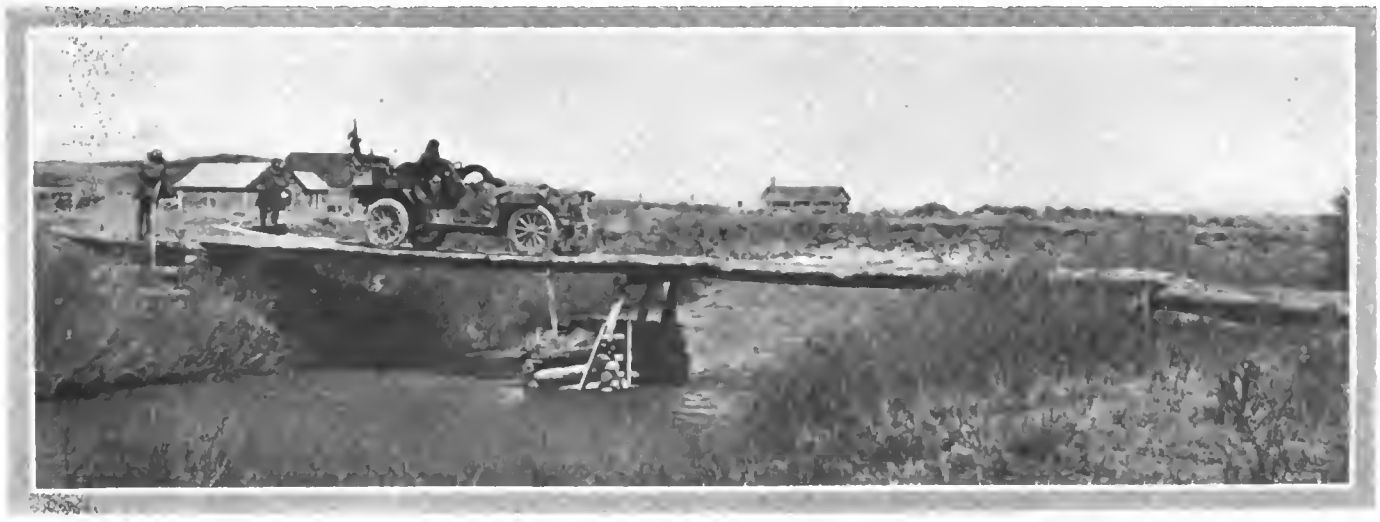
Mr. Morrell stated that the club's sanction would not be withdrawn and that the club's position had not been varied; that it would see that the contest be properly conducted and that the $5,350 in cash prizes, which had been deposited by M. Robert Guggenheim and which was now in the hands of the Automobile Club of America, would be paid to the winners.

When asked if the number of entries would have any effect on the attitude of the club, Mr. Morrell said: "Not the slightest; if the Seattle Automobile Club and the Alaska-Yukon-Pacific were prepared to start only one car June 1, the club will be ready to carry out its obligations as the sanctioning body." This statement should set at rest, once and for all, the rumors that have been given circulation that the contest did not have the full support of the Automobile Club of America.

C. M. Hamilton announced Wednesday that he has practically completed arrangements to enter the transcontinental contest, with an Isotta standard 40-horsepower car.

Seattle now has an Aeroplane Club, through the organization, in the western city, of a number of those interested in aviation, and that the club is in earnest is shown by the trip of its president, Harry Whitney Treat, to New York, to purchase a real aeroplane, and to arrange for an affiliation with the Aero Club of America.

Twenty entries have been received by the Swiss Aero Club for the Zurich Gordon-Bennett event, starting on October 3. This is three less than last year, but it may be that late entries will be forwarded. Switzerland, Germany, France, Italy, and Belgium are represented by three balloons each, Spain two, and England, the United States, and Austria pin their faith to one.



Typical Western Country Met with in Wyoming, Where Bridges Are to Be Crossed with Much Caution.

In Front of the Pennsylvania Capitol in a Franklin.

In the background, at the end of the avenue, in Harrisburg, is shown the $13,000,000 State Capitol of the Keystone commonwealth. On the front seat of the air-cooled Franklin, Model G, are J. Cyde Mason, secretary of the Harrisburg Motor Club, and James Bell, of the Harrisburg Board of Trade.

An Amateur Trans-Continentalist.—From San Francisco to Portland, Me., and then back to the Pacific Coast by way of the northern route to Seattle is an automobile trip to be made this Summer by Mr. and Mrs. C. A. Littlefield, of Oakland, Cal. Mr. Littlefield has given considerable time and expense to preparations, both as regards his car and routes and roads. Marsh quick acting rims with Diamond 36 by 5 tires all around will be used, and the trip East, which will be by way of Los Angeles, New Orleans and Washington, includes also a visit to the Diamond rubber factories in Akron, O. The return journey will be via Buffalo and Chicago, thence for the most part along the route of the New York-Seattle endurance event.

Cameron Raises the Price.—The Cameron Motor Company of New York City, distributors of the four and six-cylinder air-cooled Cameron cars, announce an advance in price of three, four-cylinder models, as follows: Model 14, runabout, formerly $900, raised to $950; Model 14, three-passenger roadster, $950, raised to $985; Model 16, four-passenger roadster, $1,050, raised to $1,100. Harry Doherty, vice-president, states that the demand for the company's product is exceeding the most sanguine expectations, and that arrangements are already being made for the 1910 season.

Firestone Believes in Tire Contest.—With the approach of the Glidden Tour, and the discussion of penalties, H. S. Firestone, president of the Firestone Tire & Rubber Company, states that he favors a system of penalizations for tire troubles. He says: "A large per cent. of the stops en route are made because of trouble with tires, and it seems strange that tire service is not connected more closely with automobile efficiency. Penalties for weakness would inevitably raise the prevailing standard of tires."

Many One-Lung Autos in California.—H. J. Neumann, a Los Angeles, Cal., autoist, in sending along his renewal subscription to THE AUTOMOBILE says: "People out in this country are just waking up in the buying of up-to-date cars, for I think all the one-lungers in the whole country are now used here, where we have a different name for almost everything pertaining to the automobile. For instance, most folks call a windshield a glass front."

Remy Equipments for Older Models.—The manufacture of equipments for attaching its magnctos to carly models of automobiles has proven a success, according to the Remy Electric Company, Anderson, Ind. Many owners of cars built as recently as 1907, not originally designed to have a magneto have been furnished with them, and the company is making and keeping a full set of fittings, with instructions for attaching.

Benz Importers Have Open House.—To celebrate the recent victories of the Benz racing car, the Benz Auto Import Company, of America, had an "open house" on last Saturday, with "scribes and good fellows" as guests. Incidentally the Sir Thomas Dewar $2,000 trophy, which was won at Daytona, was shown, and the improved business outlook made the cause for felicitations.

Cheyenne, Wyo., announces a Motordrome.—The Cheyenne Motor Club has announced that it has completed plans for the construction of a five-mile automobile race track to built near the city. There will be a course within a course, banked curves and other features.

New Men in Gramm-Logan Company.—The Gramm-Logan Motor Car Company, Bowling Green, Ohio, has added to its officials several leading men of the Lima Locomotive & Machine Works. Increased capital and factory facilities have been obtained.

RECENT BUSINESS CHANGES.

Gibney Brothers Have New Quarters.—James L. Gibney & Brother, the Philadelphia distributors of Continental tires and general dealers in Gibney solid tires and accessories, in order to relieve a cramped condition in their present quarters at 211-213 North Broad street, have secured the building next door at 215-217, and are having it thoroughly overhauled. The new store will soon be ready and will give a large, well-lighted salesroom, offices, stock rooms and tire repair shop. The building is a large three-story one, equipped with an electric automobile elevator and power.

Four Traction Auto Company Looks for Factory Site.—Minneapolis may be the location of the Four Traction Auto Company, the maker of the Kato trucks, according to factory officials. At present the machines are built at Mankato, Minn., but the necessity of increasing production has made a larger plant imperative, and Minneapolis sites have been examined. The concern was recently capitalized at $200,000, and has a large business in making trucks, patrol and fire wagons, all with the four-wheel driver, which has been such a marked success.

Luitweiler Pumping Engine Company Moves East.—Rochester, N. Y., will soon be the location of the Luitweiler Pumping Engine Company, now situated at Los Angeles, Cal. The plant of the American Laundry Company has been purchased, and will be occupied about June 1, after extensive alterations are completed. The concern is engaged in building automobile fire apparatus, and steam, gasoline and electric pumping engines.

Utica Pliers and Nippers Marketed Direct.—The Utica Drop Forge & Tool Company, of Utica, N. Y., is now marketing its products, pliers and nippers, direct to the trade. The new policy was begun on April 1 and has been found successful. The plant is in full operation, more than an acre of floor area being under one roof, with over a mile of industrial railroad between the various departments.

Davidge Motor Car Company in Binghamton, N. Y.—John M. Davidge, of Binghamton, has filed a certificate with the county clerk, announcing that he will go into business under the name of the Davidge Motor Car Company.

Birmingham Auto Company Changes Hands.—Leo Loeb and J. H. Loveman, of Birmingham, Ala., have purchased the Birmingham Auto Company, carrying with it the agency for the Chalmers-Detroit and Thomas cars.

Nesmith Buys Auto-Shine Company.—The C. I. Nesmith Company, Reading, Mass., has recently purchased the Auto-Shine Company, of Buffalo, N. Y., manufacturers of "Auto-Shine" a varnish restorer and polish.

IN AND ABOUT THE AGENCIES.

Fry Spark Plugs.—The Standard Sales Company, of New York City, is introducing to the trade the Fry spark plugs, made in 1-2 inch, metric, and A. L. A. M. sizes, with interchangeable porcelain and mica cores. Manager J. Stewart Smith is enthusiastic over the future, which the simplicity and reliability of the plug insure.

United Manufacturers Establish Branch Offices.—The following distributing centers and branch offices have been opened by the United Manufacturers: Chicago, 1430 Michigan avenue; Detroit, 225 Jefferson avenue; Cleveland, 1932 Euclid avenue; Philadelphia, 422 Commerce street; Boston, 109 Massachusetts avenue.

Rambler, Atlanta, Ga.—The Rambler has just broken into Atlanta, with Baynard Willingham in charge of the agency. A warehouse has been converted into a comfortable and commodious garage at 70 South Forsythe street.

TAXICABS AND TRANSIT.

Philadelphia to Have Auto Patrols.—Director of Public Works Clay is contemplating the installation of an automobile patrol service. Garages for this service are to be built at the new Thirty-sixth District Station at Hunting Park and Germantown avenue, and also at the Twenty-first District Station at Woodland avenue and Market street.

Autos to Collect Minneapolis Mail.—Major W. D. Hale, postmaster at Minneapolis, has requested the government to furnish two automobiles for use in collecting mail, and it is believed that they will be furnished. The superintendent of delivery has gone to Milwaukee to inspect the operation of the auto mail wagons there.

Stage Line in New Haven, Conn.—A Knox sight-seeing bus of 30-passenger capacity, has been put into service by S. A. Lewis, on several streets of the city. Other cars of the same type will be used when needed, running as buses during the day and evening, and open to engagement for Savin Rock and other resorts along the Connecticut shore.

Pueblo, Cal., Get Taxicabs.—A Ford enclosed cab has been put into service here as the first of the taxicabs received by Robertson & Marks. It was run over the roads from Denver and has made a favorable impression in "sunville."

McKinney, Tex., to Establish Bus Service.—An automobile service will shortly be installed between Blue Ridge, Melissa and McKinney. A number of prominent men of Blue Ridge are interested in the service.

More Taxicabs for Dallas.—Increasing popularity of taxicabs has evinced itself to such an extent that four more machines are to be added to the present service of thirteen.

PERSONAL TRADE MENTION.

Percy Neel, president of the Automobile Sales Corporation of Philadelphia, which handles the Peerless and Cadillac, sailed last Saturday for a six weeks' trip abroad. Mr. Neel has just recovered from a long illness, and his physicians prescribed a rest and ozone of a sea voyage to complete the cure.

Cadwalader Washburn Kelsey, of Philadelphia, who is not unknown to fame in connection with the Maxwell car, will be married June 2 to Miss Mariah Sharwood, of Bryn Mawr, in the Church of the Redeemer at that place. After a honeymoon abroad, Mr. and Mrs. Kelsey will reside in Tarrytown, N. Y.

G. C. Lewis has joined the selling force of the New York branch of the E. R. Thomas Motor Company. Mr. Lewis was formerly Boston manager for the Dragon car, and prior to that time was manager of the Wayne Automobile Company's branch in Boston.

Edward A. Kingsbury has accepted the position of business manager of the Chase Motor Truck Company, of Syracuse, N. Y. He was formerly connected with the Hudson Portland Cement Company.

P. O. Sheenan has been appointed city salesman for Boston for the Republic Rubber Company, of New York, and will make his headquarters at the local branch at 735 Boylston street.

Lee Dykeman for some time associated with the Dayton Motor Car Company has been appointed superintendent of the Firestone Automobile Company, of Columbus, Ohio.

R. E. Ross, of the Quaker City Motor Club, has been appointed chairman of the contest committee, by President Berger, succeeding the late Ferdinand M. Johnson.

NEW AGENCIES ESTABLISHED.

Knox, Pittsburgh, Pa.—Hiland Automobile Company, in addition to the Peerless and E-M-F.

Winton, Altoona, Pa.—Hollidaysburg Automobile Company, Montgomery and Mulberry streets.

Dixie Flyer, Minneapolis.—Sangstrom Motor Company. For the entire Northwest.

Chalmers-Detroit and Thomas, Birmingham, Ala.—Birmingham Auto Company.

Columbia, Chicago.—Fred R. Jenkins Company, 1330 Michigan avenue.

Rider-Lewis, Minneapolis.—Segerstrom Automobile Company.

Elmore, Waterville, N. Y.—Orrin Terry and Fred C. Bufford.

Maxwell, Brainbridge, Ga.—E. T. Hines and T. M. Battle.

Hupmobile, Milwaukee, Wis.—Samuel B. & Harry C. Taylor.

Peerless, Fort Worth, Texas.—Hugh H. Lewis, Jr.

Ford & Overland, Washington, N. J.—Hoyt Sharp.

RECENT INCORPORATIONS.

Union Auto Company, Little Rock, Ark.—Capital, $10,000. To buy, sell, rent, repair, automobiles. Incorporators: President, C. B. Ledbetter; vice-president, C. K. Lincoln; secretary, L. E. Polk; treasurer, W. L. Hemingway; R. L. McKinney, J. F. Loughborough, D. H. Cantrell, J. L. Dibrell.

Garny-Mehserle Machine & Auto Company, Rochester, N. Y.—Capital, $2,000. To manufacture motors, engines, wagons, cars and vehicles of all kinds. Incorporators: George Garny, Theresa Garny, Henry Mehserle and Katherine Mehserle.

Plainfield Auto Sales Company, Elizabeth, N. J.—Capital, $25,000. Incorporators: C. C. Brown, C. C. Rocap and S. A. Aldrich. To manufacture and deal in automobiles of all kinds, and to deal in supplies and fixtures.

American Automobile Association Publishing Company, New York.—Capital, $2,000. Incorporators: Lewis R. Speare, F. H. Elliott and J. H. Bruce. To conduct a printing and publishing business.

Munsing Motor Car Company, Jersey City, N. J.—Capital, $1,000,000. To do a general manufacturing business. Incorporators: W. H. Buresmith, J. B. Franklin, C. H. Bellows, Jr.

Stoughton-Folkins Company, Portland, Me.—Capital, $10,000. To manufacture motors, engines and vehicles. President, M. S. Folkins; treasurer and clerk, P. T. Stoughton.

Park Garage Company, Asbury Park, N. J.—Capital, $125,000. Incorporators: A. M. Fisher, G. F. Mitchell and M. W. Bates. To conduct a general garage business.

Preston Auto Improvement Company, Boston.—Capital, $100,000. Incorporators: R. N. Gowing and F. G. Preston. To conduct a general automobile business.

L. B. Repair Company, New York.—Capital, $10,000. To deal in and repair automobiles. Incorporators: J. A. Lewis, F. H. Bonner and W. A. Rue.

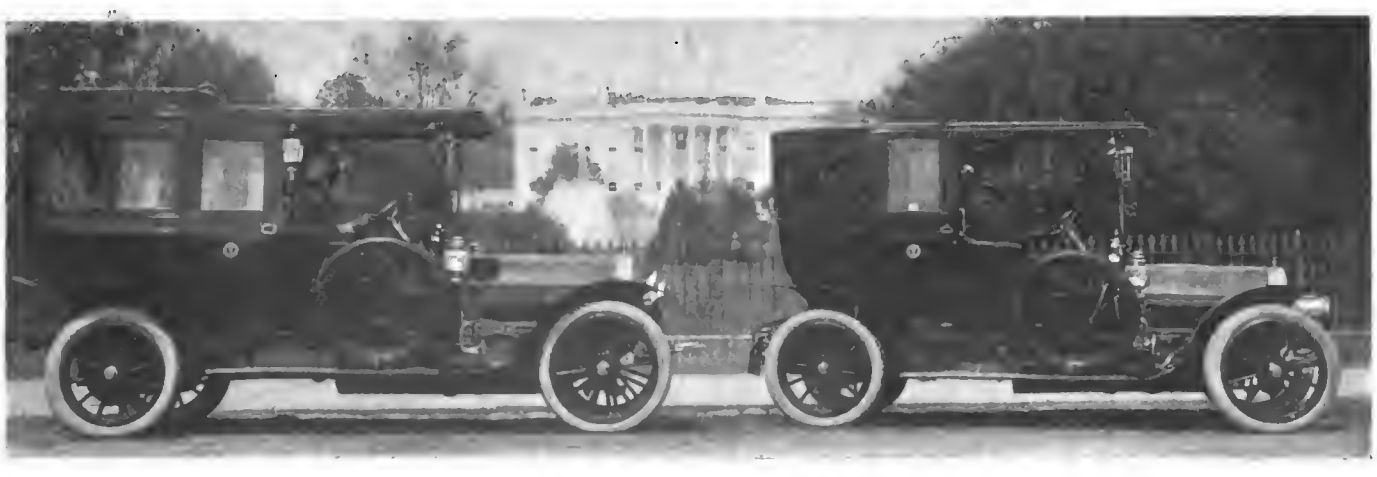
McDuffie Motor Car Company, Denver, Col.—Capital, $25,000. Incorporators: J. W. Ebert, C. H. McCausland, J. H. McDuffie.

McCord Manufacturing Company, Springfield, Ill.—Capital, $750,000. Maine corporation to manufacture automobile supplies.

Albert Sterne Motor Car Company, St. Louis.—Capital $15,000. Incorporators: Albert Sterne, M. L. Weiss, L. A. Fassett.

NEW TRADE PUBLICATIONS.

Xargil Manufacturing Company, Utica, N. Y.—Mufflers which do not create a back pressure upon an engine have long been sought, and those which create a vacuum would give an ideal condition. The Xargil Manufacturing Company is now producing a muffler which is known as the Xargil Vacuum Muffler, and is described in a new catalog published by this concern. This booklet includes the reproduction of a curve, plotted from a series of tests made of the muffler at the Franklin Company's works in Syracuse. This shows that at 1100 revolutions of a Model D Franklin car the pressure in the muffler is but .4 of an ounce. The muffler consists of an outside elongated steel cylinder, with two smaller interior ones, divided in turn into some thirty compartments interconnected. The exhaust is divided into innumerable small jets, as explained by the booklet.



Six-Cylinder 48-Horsepower Suburban and Six-36 Landaulet Pierce Arrow Cars in the White House Service, at Washington.

Information for Auto Users

Red-Head Spark Plugs.—These plugs are made and marketed by the Emil Grossman Company, 232 West Fifty-eighth street, New York City, and the design, as shown by the illustration, is along the accepted lines of spark-plug construction, with features embodied therein designed to give special results to the user. The porcelain cores are made of a special clay, aged for nine months by a new process which does not make them brittle. These are then formed and baked, and can be thrown with great force against the floor or a hard surface, but will only rebound and not break. Under a red-hot heat it is asserted they do not even bend, and in exhaustive tests made by the Electrical Testing Laboratories, in testing for the dielectric strength it was found that the Red-Head porcelain under 17,400 volts arced over its surface; whereas of two porcelains taken at random one was punctured at 8,000 volts and the other at 6,600, arced through a puncture.

RED HEAD PLUG.

The shell or base is substantial and compact, turned from solid steel, with a solid brass bushing nut to surround the porcelain or mica core. The bushing may be forced down upon the shoulder of the porcelain to make a tight joint. One copper asbestos washer is used in packing the core into the shell, and it is claimed that sufficient packing is used to prevent its blowing out. Still another feature is in the electrode, which is extra large and heavy, so that it will stand any heat from either a magnet or battery and coil.

The order which was placed by the Emil Grossman Company for the parts of the plugs was double the largest of its kind ever made, according to Mr. Grossman. There are three types of plugs in the Red-Head class: One-half inch, A. L. A. M., and metric, made so that the porcelain is interchangeable with mica cores, and the price has been made uniform, one for any style.

Umph Roller Timer.—Among the season's best productions in the realm of ignition, is the Umph roller timer, manufactured by A. R. Mosler & Company, 163 West Twenty-ninth street, New York City. The illustration shows a front view of the timer, with the cover removed. In construction the Umph is such that wobbling is overcome and irregular wearing of the roller and shaft bearings is eliminated by the use of ball-bearings. In this timer the roller is itself a ball-bearing and is supported by a yoke which fits in a specially shaped slot in the front end of the hollow revolving shaft, so that the roller and its yoke can move radially under the

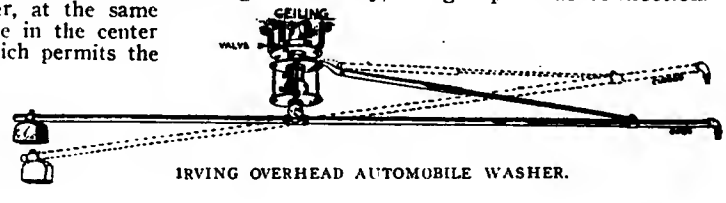
UMPH ROLLER TIMER.

action of a spring but cannot move sideways and therefore must keep true to the contact surface at all times. The shaft is mounted on two ball-bearings, the rear one running on a flanged ring and being held up to its work by a pinch-collar and arched spring-washer which fit over the rear end of the shaft. The front bearing revolves on a collar formed on the shaft itself. The segments are made of brass, each being of one piece, and are inserted by pressure from the interior of the casing. The rear end of the shaft is split, and is fastened on the timer shaft of the motor by means of the pinch-collar which in its turn is kept from sliding off by a horseshoe washer fitting into a groove cut in the shaft near its end. By removing this washer, the entire timer can be taken apart without the use of tools.

Irving Overhead Vehicle Washers.—These handy devices are made in four patterns by the I. J. Smith Mfg. Co., 4283 Park avenue, New York City. Indestructible washer No. 3, the subject of the illustration, is constructed principally of brass, and provided with automatic water cut-off. Inserted in the top of the washer is a plunger attached to a tube, which runs down the center of the washer to the movable joint in the bottom of the device. When the party washing a car desires water, he pulls down on the hose, thus drawing down the revolving arm of the washer, at the same time working valve in the center of the washer, which permits the water to run. The arm is held down in position by adjusting the counter-balance weight so that the hose-arm is a few pounds the heavier. When it is desired to close the water off, a slight upward push on the hose will send the hose-arm upward, and in such a position it is retained by a catch to the supporting arm, and the water pressure at once closes the valve on the top of the washer. The sliding counter-balance weight can be so adjusted as to automatically close off the water the moment the hose is released from the hands of the operator.

With the indestructible washer, the party using same cannot put more than 10 pounds pressure on the center by pulling down on the hose, for on placing more than that force on the revolving arm, the spring and counter-balance allows the arm to give down, and when the man lets go the hose the arm goes back into position.

The other Irving washers are Nos. 1 and 2, and the Every Ready. These are not made with automatic cut-offs. They have arms varying from 4½ feet to 6 feet in length. Electric-light equipments can be ordered with washers Nos. 2 and 3. All washers are secured to the ceiling by four lag screws, and to the end of the revolving arm is attached the hose, which is always hanging and ready for use. By their use hose can not be run over, trod upon, or rot out from water lying in it, and it also prevents the hose kinking.



IRVING OVERHEAD AUTOMOBILE WASHER.

Shippey Shock Absorber.—"In all our output during the last three years, we have yet to hear of one broken spring," is the statement made by the George E. Shippey Company, Pittsfield, Mass., makers of the Shippey shock absorber, in setting forth its claims for a record. As can be seen by the illustration, the Shippey is striking in its simplicity of construction and method of operation. The springs are made of the best crucible spring steel, oil tempered, and all wearing parts are specially hardened. No adjustment is necessary, once the absorber is applied to the car, and the easy movement of the springs is not affected on the smooth roads, but the device comes into play on the bumps. The absorber that is used on the front of the car is attached directly to the frame of the car at its top, and the connection on the bottom is made with a special clip. The rear absorber is attached inside of frame, under the body, using a plate as connection.

SHIPPEY SHOCK ABSORBER.

Vol. XX New York—Thursday, May 20, 1909—Chicago No. 20

THE AUTOMOBILE

Washington's Reliability Supplies a Tie

By H. G. Ward.

Packard

Matheson

WASHINGTON, D. C., May 18.—Packard and Matheson are tied in the top notch class of the reliability run of the Automobile Club of Washington, held Saturday last over a trying 165-mile course, which included Maryland and Pennsylvania roads, both good and bad. Apparently the Packard, driven by John Day, had survived the run with a perfect mechanical and road score. Subsequently a protest against this decision of the technical committee was filed by William Orme, entrant of No. 13 Matheson, which finished second with W. B. McBurney at the wheel, its score being four points away from perfect. Mr. Orme himself drove another Matheson car, which landed in the third place in the summary of Class A, with 26 points less perfect. The protest was based on the fact that the Packard had a loose grease cup on the rear spring, and, furthermore, it was claimed that the driver had worked on the car after the conclusion of the run and before it was turned over to the technical committee for examination. It is stated that at first the driver thought something was wrong with the ignition system, and subsequently he discovered that the trouble was due to the loss of a cover over the air valve in the carbureter. The driver had something to say about its having been tampered with, but eventually the cover was found in the pan underneath the engine.

The technical committee consisted of Robert B. Caverly, Fulton R. Gordon, and H. Chadwick Hunter. The cup for the class was a handsome one offered by the Washington *Post*. Exactly what will be done with the tie is not known at this time, but it is among the possibilities that a run-off will be arranged in the near future.

Class B, the cup for which was donated by the Washington *Star*, had a Model 17 Buick winner, perfect in its road score, but having a penalization of two points for a dead battery.

Class C, with the Washington *Times*, the donor of the cup, fell to the Model T Ford roadster, penalized fourteen points, ten of which were for lost time and four for technicalities reported.

Twenty-one cars were entered in the contest, but three failed to start. A Model KA Maxwell did not arrive in time from the factory, a Chase delivery wagon was scratched because certain gears did not come to hand, and a Thomas-Detroit was disqualified because its observer did not show up.

The course was one calculated to try the endurance of cars and drivers, being over various kinds of roads and crossing three mountain ranges. At Waynesboro, Pa., which was half the distance, a half hour's compulsory stop was made, where the contestants were permitted to replenish with gasoline. Water and oil could be taken on at any time under the rules.

The two Matheson entries showed a good performance, the No. 13 losing only four points for lost body bolts, having otherwise a perfect road and technical score. The other Matheson lost 24 points, according to the observer's time record.

Concluding Preparations for the Start of the Reliability Run of the Automobile Club of Washington

Fourth in Class A was the Franklin with 45 demerit points, 4 being for four lost spring clips, 12 on the observer's technical report, and 29 for being late.

If there was one car penalized that certainly had a tough break in the luck bag it was the Oldsmobile, driven by O. W. Hoffman. This car was penalized 4 points for being late at the finish, a condition brought about by the melting of a connecting rod bearing, for which an additional penalty of 50 points was assessed. This happened only a few yards from the finish line and the car had a perfect mechanical and road score up to this time. The fact that the car was entered late, and was taken right off the sales floor of the local Oldsmobile dealer without having any tuning up whatever, accounts in a measure for the trouble.

Another Oldsmobile, a Model X Special, also came in for a bit of hard luck. It sustained a penalty of 65 points; 33 of which were levied on the observer's report. It also had 2 points against it for a turned shackle, 3 points for a loose frame bracket, 25 points for a damaged wheel, and 2 points for being late. Twelve miles from the finish this car, driven by Tyser, cast a front tire and it came home on the rim, being only a minute late. Tyser did a sensational piece of driving that was acknowledged with applause by the hundreds at the finish line.

The Columbia lost 2 points for a loose spring clip, 46 points for being late, and 25 points on technical examination. The Pullman sustained a loss of 154 points, 2 of which were for a loose muffler pipe, 2 for lost chassis bolts, 10 for a loose thrust bearing, 110 on the observer's report, and 30 for being late. The other Packard suffered the heaviest penalty of all, due to a broken spring. It lost 1,860 points for being late, 2 for a broken seal, 35 for broken spring leaves, 2 for a loose spring clip, 2 for a loose muffler pipe, 2 for a loose mudguard, and 38 on technical examination.

In Class B the Chalmers-Detroit was assessed 16 points on the observer's technical report. Twenty-six points went against the Stoddard-Dayton, 2 for a broken oil lead, 1 for a loose spring clip, 2 for a turned shackle, 10 for lateness, and 10 on the observer's technical report. The Wayne was disqualified because it was removed from the official garage before the examination by the technical committee.

In Class C the Reo roadster had a loose oiler when the car started, but the driver forgot to declare this fact to the committee the night before the start. The technical examination disclosed this fact and 20 points were charged, together with 2 points for stalling the engine twice. A Ford, driven by Machin, had a time penalty of 22 and 2 points for a loose muffler pipe.

The two Brush entries had hard luck. No. 11, driven by Nichols, had a broken web, for which it was assessed 50 points; 284 points for being late; 25 points for a lost tool kit, and 2 points technical. The other Brush had a loose cylinder nut, costing 2 points, while 70 points were levied for being late.

Officials in Charge of the Reliability Run.

From left to right: Robert B. Caverly, referee; H. C. Hunter, judge; Wm. D. West, pilot and president of the club, and J. K. Heyl, clerk. An energetic quartet of Washingtonians.

CLASS A—CARS COSTING $2,500 AND OVER.

Car.	H.P.	Bore	Stroke	Model	Driver	Penalty
1. Packard	30	5	5 1-8	30	John Day	4

SAVANNAH TO AUGUSTA ENDURANCE RUN.

SAVANNAH, GA., May 17.—The Savannah Automobile Club is arranging for an endurance run from this city to Augusta, a suggested date being May 31. An extensive prize list is being planned, and a large entry is assured for the event.

DATE FOR DELAWARE ASSOCIATION RUN.

WILMINGTON, DEL., May 17.—At a meeting held recently the Delaware Automobile Association selected Saturday, June 12, as the date for the proposed sealed time run. The course will be from Wilmington to Dover and return.

"SONS OF OLD ELI" ARRANGE HILL CLIMB.

NEW HAVEN, CONN., May 17.—Shingle Hill will be enlivened for the second time by the annual hill climb of the Yale University Automobile Club, on May 26. Motorcycles and automobiles will have the right of way on that day, with three classes for the former, a popular mode of transportation around this city among the students, and seven classes for autos. Under the sanction and rules of the A. A. A. there will be a price classification for the cars, and a piston displacement for the two-wheelers, with free-for-alls for both. Shingle Hill is a winding road of macadam located near this city, about 5,000 feet long, and with grades varying from nothing to 20 per cent. There is an abrupt rise at the start, a short level stretch, at the end of which there is a sharp S turn and a steep climb to the finish. The record is held by David Bruce Brown, who made the ascent in the Fiat Briarcliff racer in 1:06 4-5.

Robert Lee Morrell will act as referee and C. H. Gillette as A. A. A. contest board representative. Post & Lester have donated a valuable cup for the free-for-all in the automobile division, and a gold medal will be given by the club to the member who makes the fastest time of the day. Cups will be given to the winner of each event. Entry blanks may be obtained from R. E. Wiles, secretary Yale Automobile Club, Yale Station, New Haven, Conn.

FOR THE BABY TONNEAU CLASS.

DETROIT, May 17.—Gliddenites contesting in the baby tonneau class will have an added incentive this year, as the result of action taken by the city of Detroit. When it was first determined that Detroit would be the starting point for the big tour in July Mayor Breitmeyer urged that the municipality offer a suitable trophy, to be put up annually, as is the case with the other cups that feature in the Glidden tour. The idea met with general approval, and the sum of $250 was appropriated for the purpose. Rivalry was keen among local jewelers for the honor of furnishing the cup, the design submitted by Wright, Kay & Company finally being accepted by the committee. The cup is a massive affair of china, beautifully decorated with hand painting.

The Wyoming Auto Transit Company, which runs automobile stages from Rock Springs to Yellowstone Park is preparing to make a test of the autofreight truck. The distance from Rock Springs to Pinedale is 120 miles. It is expected to make the distance in 10 hours with a cargo of four tons.

AUTOISTS FIGHT GARAGE ORDINANCE

MILWAUKEE, WIS., May 17.—Several sections of the proposed garage ordinance for this city have been considered so drastic that the local tradesmen and the automobile club have determined to fight its adoption by common council. Among the provisions are the following:

No garage may contain more than ten gallons of inflammable liquid in approved safety cans or more than 550 gallons in underground storage tanks. Not more than 120 pounds of calcium carbide may be kept. All fires and lights shall be extinguished before the car is brought into the garage and shall not be lighted while the car is in it. No stove, forge, torch, boiler or other furnace, flame, fire, or fire heat, no electric motor, hoist or exterior sparking device, and no artificial light, except incandescent electric globes will be permitted in any garage or portion of a garage that is not provided with an entrance on the outside of the building and separated from the garage by unpierced, approved fire walls and doors. Electric charging apparatus shall not be installed in a garage equipped for handling gasoline or other volatile inflammable liquid until the plans and method of installation have been approved by the fire chief and building inspector. The ordinance absolutely forbids smoking. A plentiful supply of sand must be kept on hand at all times for fire fighting purposes.

DOZEN PERFECT SCORES IN TRENTON RUN.

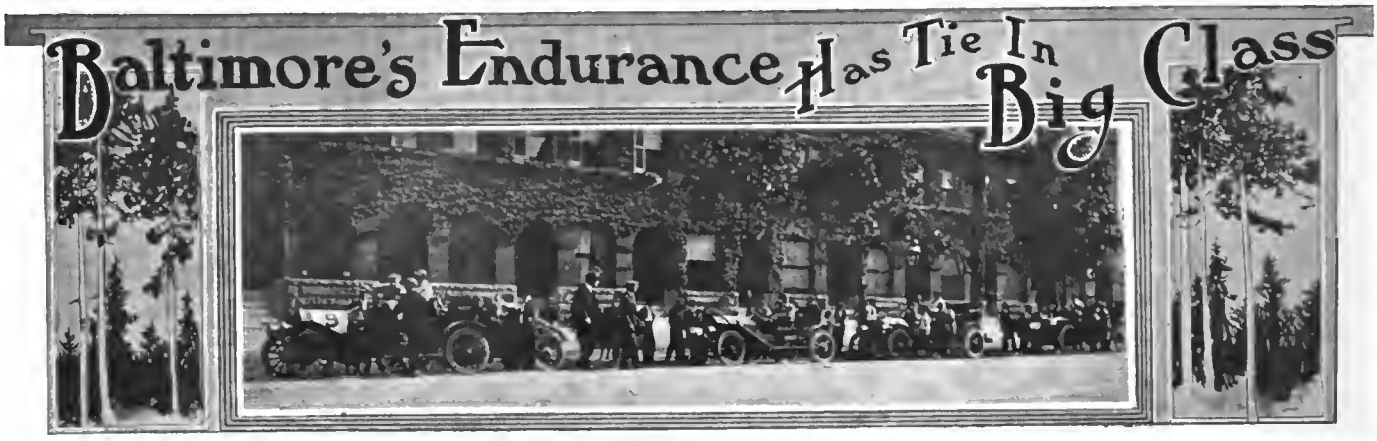
TRENTON, N. J., May 17.—In the Delaware Valley endurance run held to-day by the Trenton Dealers' Association there were twelve cars with perfect scores, out of 21 starters. The course was about 158 miles in length, going through Princeton, Bernardsville, Hackettstown, Easton, and down the valley to the finish. The perfect score cars and drivers were: Peerless, Manning; Pullman, Hardesty; Oldsmobile, Druck; Crawford, Gillim; Stoddard-Dayton, Moon; Midland, Hayes; Regal, Aller; Ford, Mosher; Mercer, Wehner; Overland, Van Horn; Buick, Eisenberg; Maxwell, Toman. The cars ran on an eight-hour schedule, with penalties for being ahead or late, and for motor stops.

TIRES BURNED IN AKRON, O., FIRE.

AKRON, O., May 18.—Fire in the seven-story Hower block today practically destroyed the building and its contents, causing a loss which it is thought will aggregate $1,500,000. The building was occupied entirely by light manufacturing companies. The cause of the fire is unknown. Both the Goodrich Rubber Company and the Diamond Tire Company had thousands of dollars worth of tires stored in the building. The tires are a complete loss. There is about $800,000 insurance on building and contents.

Clutch Testing of the Technical Inspection at the Conclusion of Washington Endurance Run.

Baltimore's Endurance Has Tie In Big Class



Lined Up Near the Automobile Club of Maryland, After the Return, for the Tests and Technical Examination.

SUMMARY OF WINNERS.
Winton and Packard Tie in Class A.
Studebaker Takes Class B.
Franklin Perfect in Class C.

BALTIMORE, May 16.—Winners in the sealed bonnet contest and endurance run conducted by the Automobile Club of Maryland from Baltimore to Gettysburg and return, yesterday, were cars Nos. 1, 2, 3, 4 and 11. Cars Nos. 1 and 2, a 48-horsepower Winton, driven by B. B. Tathum, and a 30-horsepower Packard, driven by E. R. Marshall, were tied for first position in Class A, for touring cars over 30-horsepower, each being penalized two points. A loose fender bolt caused the Winton car to lose its points on technical examination, while the Packard was prevented from making a perfect score by taking on a quart of water. Car No. 3, the 40-horsepower Studebaker driven by Robert Yerger, captured the Class B event for tourabouts of over 30 horsepower, with a perfect score, while the 28-horsepower Franklin, driven by John L. Burns, was the headliner in Class C for touring cars under 30-horsepower, with a perfect mark. These were the only two cars of the twelve contestants that made the run without having a bad mark registered against them. The winner in Class D, for tourabouts under 30-horsepower was the tiny 16-horsepower Hupmobile which was penalized two points because the chauffeur put some water in radiator. This infraction put two bad marks in the water test column for this midget machine. Even the two perfect score cars were at first held up on small technicalities, the Studebaker for dropping a New York license and the Franklin for using oil on the engine through a misunderstanding. The penalties in these two instances, however, were waived.

A novel stunt was put through by the entrant of the Winton cars. This was nothing less than the act of fastening over the usual quadrant, a steel plate with but two notches cut in it. In this way, it was impossible to engage other speeds than the high and the reverse as per the two notches, the steel plate covering up all others. The idea was to demonstrate the flexibility of the "six" in a startling but convincing manner. Owing to this plate, at one control it was necessary to run the engine no less than three hours and five minutes. The Winton arrived this much ahead of time, and had to keep the motor running or lose points.

The distance covered by the contestants was 136.5 miles and for the most part was over rough and rocky roads which proved a severe test for the machines. From Baltimore the motorists headed for Frederick, Md., where at James E. Solt's garage was the first checking station. This was a distance of 46.5 miles, during which many places of interest were passed. There were

SUMMARY OF THE SEALED BONNET RUN OF THE AUTOMOBILE CLUB OF MARYLAND, MAY 15, 1909.

CLASS A—FOR TOURING CARS OVER 30 HORSEPOWER.

OFFICIAL CARS.

Winton.....Pathfinder.
Packard.....Pilot.
Oldsmobile.....Press Car.
Packard.....Pacemaker.

Referee—Frank S. Darling.
Technical Committee—Dr. H. M. Rowe, George R. Snodeal, and Frank W. Darling.

a number of water bars between these two points, but outside of these the going was comparatively smooth and easy. The first car to meet with a mishap was the 30-horsepower Packard car, driven by George A. Yakel, which was the pilot car. The pilot had departed from Baltimore at 6.54 A. M., a little more than an hour ahead of the first started in the run. When the Packard reached a point just outside of Ellicott City, about 12 miles from Baltimore, it lost its gasoline tank. This caused such a delay that it was passed by the pacemaker, also a 30-horsepower Packard, driven by E. R. Marshall, which, together with several other cars, arrived at Frederick ahead of the pilot. The latter was also behind in its arrival at Gettysburg. These accidents caused the pilot to be penalized 1,000 points on technical examination. The only other serious accident was the breaking of a pin in the differential of No. 5 car, a 35-40 Oldsmobile, driven by E. L. Leinbach, which made it necessary for Mr. Leinbach to break the seal. The car was immediately withdrawn, but after being repaired was taken over the course within the time limit by O. C. Hoff, Mr. Leinbach having in the meantime taken the steering wheel of the press car Oldsmobile.

As a means of settling the tie with the Packard, the Winton people propose to seal up everything on both cars but the gasoline and oil tanks, and then run the two cars in competition until either one or the other fails.

From Frederick the route was by way of Thurmont and Emmitsburg to Gettysburg, where the second checking in was made at the Gettysburg Motor Car Company's garage. There the motorists were allowed an hour for luncheon or a spin around the battlefield. Those that laid over were permitted to stop their motors without suffering a penalty, providing no work was done on the cars.

From Gettysburg the trip was through Littlestown, Pa., Westminster, Reisterstown, Chattolanee and Eccleston to the Pimlico entrance of Druid Hill park. From there the cars went through the beautiful park to the Automobile Club of Maryland, the last checking station. Two and three-quarter hours were given the cars for the run from Baltimore to Frederick; two hours running time from Frederick to Gettysburg, and three and three-quarter hours for the return trip from Gettysburg to Baltimore. Two of the cars that were entered in the contest did not start. They were the 20-horsepower Herreshoff, by the Ford Auto Company, and the 20-horsepower Reo, by Little Joe Wessenfeld. The other cars and the mishaps for which they were penalized for were the 26-horsepower Maryland, six blowouts; the 35-40 Gaeth, a leaky gasoline tank and muffler pipe broken; Stoddard-Dayton, 45-horsepower, loose water connection; Overland, 30-horsepower, pin out of rear spring and loose distance rod and wheel; Thomas, 60-horsepower, throttle control bad and stopped motor; Oakland, 20-horsepower, pin lost from front spring and engine pound.

SOUTH AROUSED BY NEW YORK TO ATLANTA HIGHWAY

ATLANTA, GA., May 17.—When a national highway from New York City to Atlanta was proposed by the New York *Herald* and the Atlanta *Journal*, to be fostered through the holding of an automobile contest between the two cities just before the opening of the national automobile exhibition here, it was hardly likely that the interest aroused was imagined. There has been nothing suggested in the memory of the Southerners of to-day which has caused this entire section of the country to stand up and concentrate its enthusiasm as has this movement. If a hundred circuses, the love of all people, should travel through the States of Virginia, the Carolinas and Georgia, it is hardly likely that the sentiment of welcome would be more hearty. Every little town on the three proposed routes, every county, mayors, congressmen, legislators and governors, are vieing with each other in expressing support of anything that will give the South good roads, and consequently do more to benefit it than anything that has happened since the war. Railroads only tap a portion of the country, and it is hoped that with trunk lines of splendid highways there will be an awakening of great economic importance.

The two newspapers have offered prizes to the counties which have the best roads, the *Herald* giving sums of $1,000, $500 and $200 for the sections between New York and some point midway to Atlanta, and the *Journal* giving corresponding amounts for those in the Southern half. Indeed the whole movement below the Potomac River has become one of the road question with the automobile endurance contest a mere means to an end. The action of the National Association of Automobile Manufacturers in deciding to hold an exhibition of national importance in this city from November 6 to 13 has been very gratifying, and the interest will be greatly increased by the endurance contest, for which cash or plate prizes will be given. The fact that there are three routes under consideration and the one selected must qualify by its highway condition has given additional incentive to work.

The routes suggested are combined from New York to Philadelphia, when one goes west to Harrisburg, thence down the Cumberland Valley to Harper's Ferry, and through the Shenandoah Valley to Lexington, crossing the mountains to Martinsville and Salisbury, N. C., where it joins the route of the second suggestion. From Philadelphia to Washington there are two routes combined, one of which from the national capital goes to Rapidan, Charlottesville, Lynchburg, Danville, Greensboro and Salisbury, the two from that point running to Atlanta via Charlotte, Blackburg, Spartansburg, Hartwell and Winder.

The third course leaves Washington for Richmond, Petersburg, Raleigh, Columbia, S. C., and Royston, joining the others at Winder. The distance is about 900 to 1,000 miles on any of these routes, and so it is a matter of the one offering the best road. It has been suggested by the Richmond people that the Lincoln highway, being considered by Congress, would be more appropriate if built between Washington and Richmond, thus cementing the North and the South, than between the capital and Gettysburg. Another feature of this route is that it includes the capitals of all four of the Southern States, Richmond, Raleigh, Columbia and Atlanta. The difficulty is that the roads in this section are probably the worst to be found, taken as a whole, whereas those on the route through Harrisburg and the Shenandoah Valley are the best, except that they abound in water breaks and may be cut out on that account.

The first scout car has left Atlanta, a White steamer, driven by E. W. Gans, with the others of the party: Frank S. Welden, president of the Interstate Highway Association; E. H. Inman, president of the Fulton County Automobile Club; John S. Cohen, managing editor, and a *Journal* staff man. Early in June it is planned to start a car from New York and work down, the notes taken being responsible for the decision as to the best way South. Interest unquestionably is general and spreading.

MOTORDROME FOR ATLANTA WINTER RESORT.

ATLANTA, GA., May 17.—Feeling that an automobile race course is a valuable adjunct to the modern winter resort, promoters of a magnificent hotel to be built in this city, on which nearly a million dollars will be spent, have started plans for a motordrome. Asa Candler, Jr., and some of the wealthiest young men in the city have organized a company and secured options on 200 acres of land on which they say that about $250,000 will be expended in making it a race track of note, with grand stands and accompanying buildings. This is part of the plan, it is stated, for the popularizing of the new hotel, and on a two-mile circuit there will be races several times a year.

ONE-GALLON CONTEST TOLD IN OFFICIAL STATISTICS.

THE two tables shown on these pages represent the final results of the New York Trade Association's One Gallon Economy Test, and an examination of them reveals some very interesting facts. The cars are arranged in the order of their final standing, with the winning Franklin at the head.

A study of the time-distance-speed columns show that the first four car drivers all adopted the same speed. This averages 12.75 miles per hour, while the average for all but three, whose figures are not available, is 14.37 miles per hour. The winning car had a speed which was the third lowest in the contest, the highest speed noted, on the other hand, being that of a car placed last of those whose time was given. From these facts one would argue that slow speed was more economical of fuel, the speed used among the first four being about equal to one-third the normal engine speed, with the direct drive or high gear engaged. It is to be regretted in this connection that the committee in charge did not have the observers secure data relative to the gear used.

The winner, for instance, used 32-inch wheels, and the gear reduction was 3 3-4 to one. Figuring backward from these and the actual average speed, the average engine revolutions were almost exactly 477. As the normal engine speed is given as 900, this is only 53 per cent. of full speed.

The next car in order for which reduction figures are obtainable, the Lozier, figures back to less than 300 engine revolutions if the high gear was used. As this very slow speed of the engine would not be an economical one, it is doubtless true that the driver of this car pinned his faith to a lower gear than the direct drive, figuring that other economies attendant upon this would offset the transmission losses on the indirect speed.

In connection with the speed comes the question of passenger mileage. This would be equal to the number of passengers times the mileage. In the first four instances the figures are: 1, Franklin, 179; 2, Cadillac, 170.5; 3, Lozier, 119.6; 4, Matheson, 108.3. The peculiarity of these figures lies in the large gap between the first two, averaging 174.75, and the second two, which only average 113.95. The two former being so close together, practically alike, while the others are also practically alike but with 60 passenger miles intervening, makes a very funny situation.

This same peculiar situation relative to passenger miles obtained in the two-gallon test held in May, 1906. The highest passenger mileage was then made by the Mack observation car with 171.3. Between this and the two closest competitors there was a very large interval, the Frayer-Miller scoring 119.75 and the Darracq 116.1. Here the first car made a score practically identical with the score of the first two cars in the One Gallon Contest, while the two next made totals almost identical with those of the third and fourth cars of last week.

The high efficiency of the first two cars rested on the proportion of live or passenger weight to the dead weight of the cars. These cars were two of the five which weighed less than a ton, but none of the other very light weight cars made a very good showing. An examination of the column headed "live load in per cent. of total" tells the story. The two highest percentages in the contest were those of the first and second place winners.

Windage areas tell a funny story, too. The apparent use of a small area, and consequent lessened wind resistance, was not taken into account by any one, as the results show that the large

and small areas in combination with large or small scores "just happened." In the group including the four best scores is included the highest wind area, while the fifth car had the second largest. On the other hand, the lowest frontal area went with the fourteenth place. The winner had neither a large nor a small figure, and in arranging the cars for wind area would come in seventh place. The only deduction possible from these figures is that the wind resistance does not enter up to a certain speed, or certain very large area, both of which were not exceeded in the contest under consideration. As a matter of fact the car making the greatest speed of the day attained but 20 miles per hour, so that this low speed accounts for the lack of connection between the frontal area and the result. The car just mentioned, by the way, stood tenth on the area list, only two others intervening between it and the winning Franklin.

Once more the officials in charge are to be congratulated on their painstaking efforts which resulted in the tables from which the above deductions are made.

PORTER HILL FOR CLEVELAND CLIMB.

Cleveland, May 19.—Its back to Porter Hill for the 1909 climb of the Cleveland Automobile Club. This is the slope that was used last year and is ideal with the exception of its unhandy location. The bill itself is practically ideal, being an exact half mile, with just enough room at the finish for a straightaway brush. There is practically no chance of an accident, while spectators can secure an excellent view from almost any point.

The club is starting an active campaign for entries and it is believed that the lists will be better filled this year than on any previous occasion since 1906, the last time the climb was held at Gates Mills. As a whole, the local dealers are enthusiastic about the event, in marked contrast to their stand last year.

The roadway proper will be graded and smoothed by the Automobile Club officials at once, while the rural residents will give their assistance in this work, as they are in favor of the climb being held there.

WILL CLIMB DEAD HORSE HILL ONCE MORE.

Worcester, Mass., May 17.—On Saturday, June 12, the Worcester Automobile Club will hold its annual hill climb, Dead Horse hill being once more the scene of activity. This is just a mile long, starting with a slight down grade and then rising abruptly. The first grade, after crossing the bridge, is of 10.3 per cent., but this is not the worst, as up at the half-mile post is a steep stretch which averages 12.2 per cent.

There will be a full list of events, totaling sixteen. These include the first of the M. C. A. classes as far as piston displacemen and minimum weight are concerned. In price classification, however, six additional classes are provided. Event number six takes care of the motor cyclists, and numbers seven and sixteen will give the steamers their chance.

ALBANY HILL CLIMB FOR JUNE 5.

Albany, N. Y., May 17.—The second annual hill climb of the Albany Automobile Club has been postponed to June 5, that being the first day on which the roads can be closed. The entry blanks have been issued, and may be secured from the club headquarters. There are seventeen events on the program.

Chalmers-Detroit Tackling a Tough New Mexican Grade on Its Way to Mexico City.

EIGHT PERFECT IN DETROIT RUN, DESPITE WEATHER

DETROIT, May 17.—Eight perfect scores and one penalization protested to the A. A. A. was the outcome of the four days' endurance contest held under the auspices of the Detroit Auto Dealers' Association, and which ended Saturday afternoon in the midst of a good-sized cyclone.

The six hundred and fifty miles embraced in the tour were covered under conditions never before encountered by local autoists in a similar event, and the fact that eight crossed the line with a clean slate must be regarded as a high tribute to the staying conditions of the cars and the skillful work of their drivers. A week's steady downpour made it advisable to postpone the start for a day, in the hope that roads rendered well nigh impassable would improve a trifle. The run on Wednesday was through a sea of mud that made going anything but a joy. Before the cars pulled out Thursday morning J. Pluvius once more trotted out his watering pot, and the heavens leaked until participants in the run were soaked to the skin.

Friday's run was under a clear sky, but over roads from which the bottom had dropped until its recovery seemed impossible.

An hour before the close of Saturday's run the autoists ran into a rainstorm that quickly developed into a full-fledged cyclone. Barns were lifted from their foundations, trees blown down and not less than two-score telephone poles laid low across the path of the cars in something like two miles. Lee Lorimer, driving a Chalmers Thirty, was picking his way through a downpour of rain that made it difficult to see fifty feet ahead when there came a quick succession of reports and a long row of poles fell across the road with a crash, the first being but a few yards ahead of the car. Applying the brakes quickly, at the risk of putting the car into the ditch, Lorimer barely missed striking the pole. Almost at the same instant there were other reports at the rear, and looking back the occupants of the car saw three poles drop just behind them, with a Maxwell Thirty and an American Simplex just outside the barriers.

With the aid of farmers who came hurrying to the scene the three poles were lifted from the road, allowing the Chalmers car to back out and take another course followed by the other cars. This resulted in a delay of forty-five minutes on a schedule that was nearly exhausted, and from that point into the city it was a wild race to get under the wire.

There was no lack of excitement through the entire day, owing to the frightful condition of the roads. The confetti car stuck in the mud ten miles out of Port Huron, and the confetti was passed over to the press car, and finally turned over to another machine, which marked the trail. More than once the cars were held up by the mud until fence rails could be laid down to form a roadbed, all hands assisting in the task, owners of rival cars vieing with each other in helping to remedy conditions that could not under any circumstances have been worse.

Tire troubles were so numerous that after the first day they attracted little attention. One of the contestants was compelled to make nine changes in three days, all due to punctures, and others were close rivals for second place in this respect. Cars were divided into three classes, in each of which the prize was a handsome trophy donated by the local press. The entries and official score of all cars entered follows:

CLASS A—CARS LISTED AT $2,000 AND OVER.

No.	Car.	Driver.	Score.
3.	Chalmers Forty	Machesky	1.000
4.	Stoddard-Dayton	Tuttle	1.000
5.	Chalmers Forty	Vincent	1.000
8.	Stoddard-Dayton	Neumann	1.000
10.	Franklin	Carris	1.000
6.	Stevens-Duryea	Scofield	.991
1.	Pope-Hartford	Bemb	.989
2.	American Simplex	Woods	.781

CLASS B—CARS LISTED AT $1,500 TO $2,000.

11.	Chalmers Thirty	Lorimer	1.000
12.	Maxwell Thirty	Goldthwaite	1.000
13.	E-M-F Thirty	W. Lane	.994
15.	Chalmers Thirty	Bamford	.983
7.	Mitchell	Gilmore	.957

CLASS C—CARS LISTED AT LESS THAN $1,000.

19.	Maxwell Junior	Moran	1.000
18.	Hupmobile	Keeler	*.998
16.	Brush	McKenney	.923
17.	Brush	Huss	.915

*Penalization protested to A. A. A.

MISHAP IN FLAG-TO-FLAG RUN.

EL PASO, TEX., May 19.—On its first day's run into Mexico the flag to flag pathfinder, a Chalmers-Detroit Thirty, had a mishap with a serious accompaniment for its passengers. In laying out the route for an endurance contest from Denver to Mexico City, the car had left this city, crossed the international line, and was 56 miles away when a gear gave way. The car was midway between the two railroads, 46 miles from the nearest, and W. E. McCarton, a passenger walked that distance to catch a train to this city. He left shortly after with food and water for driver William Knipper and photographer F. Ed. Spooner, who had remained with car, without food, and only the water in the radiator to drink. Start was made again this morning.

Automobile Gasoline and Other Available Fuel

Part VI

By Thos. J. Fay

SPECIFIC HEAT, unlike the latent heat of evaporation, refers to the heat required to raise a given (unit) weight of the elements and compounds through one degree of sensible temperature. Latent heat refers to the evaporation of a liquid, as before explained, and specific heat is involved when the temperature is changed, without changing the state of aggregation. From the point of view of scavenging, which is a condition that follows evaporation and combustion, the specific heat of the products of combustion would have to be taken into account in an attempt to fix the magnitude of the influence of the presence of such products. Assuming that the design is good and that a motor is in proper working order, the allowable compression depends upon several factors as follows:

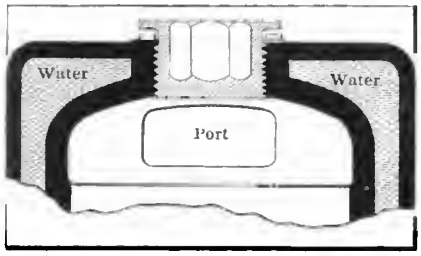

Fig. 27—Inadequate supply of water over combustion chamber is a prolific cause of pre-ignition.

(A) If liquid gasoline is entrained, upon the latent heat of evaporation of the liquid, of which gasoline is composed considering its complex character.

(B) The specific heat of the mixture, which will differ as the composition changes, it being the case that all the contents entering into mixtures are not of the same specific heat.

(C) The extent of scavenging and the heat of the spent products of combustion in the absence of complete scavenging.

(D) The temperature of the water in the water-jacket or the efficiency of the air-cooling process if air is used direct for purposes of cooling.

(E) The design of the cylinders and the extent to which the surfaces maintain an even temperature; if some one zone on the surfaces is at a high heat pre-ignition will follow, it being the case that this heated zone will be at the bottom of the trouble, nor does it matter if the zone is of small area. This trouble is most likely in cylinders of relatively large bore, in which the piston is likely to heat up at the axis of the head, which is the greatest distance away from the cooling medium, and it generally is the part in which the heat conductivity is a minimum because the metal is coated with a crust, due to elevated temperature, and the metal in the head is thin in order to have the piston as light as possible.

(F) If the valves are not properly water-jacketed they are likely to heat above the desired temperature and pre-ignition will be due to such over-heat.

(G) In some cases to make the motors as short as possible the water-jacket is so designed that but little of the cooling liquid will circulate over the dome of the combustion chamber, which is just the part that requires the greatest amount of cooling, and pre-ignition will be eminent in all such cases. Fig. 27 shows this construction.

(H) Fins, seams, perturbances, etc., due to defective designing or misplaced cores in the foundry process, will heat up and they will be the direct cause of pre-ignition.

(I) If the water circulation is not good, or if the amount of water circulated is inadequate, pre-ignition will follow. In some cases the water is enabled to short-circuit across from the inlet to the outlet without passing over the hot surfaces and this is a prolific cause of pre-ignition.

(J) Increasing compression tends to increase the terminal pressure, thus allowing and engendering an increase in speed of the motor without pre-ignition because the conditions of scavenging improves as a result.

(K) Running on a "retarded" spark results in overheating and pre-ignition is likely to follow if the other (remaining) conditions are favorable.

(L) Running on a mixture that is too rich will cause excess heating, which is indicated by a steaming cooler, and pre-ignition is likely to be one of the manifestations.

The Good That Comes from Increasing Compression.—When motors were designed in such a way that compression was not taken advantage of it was found that the power was very feeble and, as before stated, compressing the charge was the greatest stride in the direction of maximum weight efficiency. If the weight efficiency is high the power will be high, for weight of motor and in automobile work as well as in certain other zones, it is desirable to have a high weight efficiency. Under the circumstances it is not wonderful or strange if the question of compression is much discussed, and in view of differences that can follow variations in design it is natural to expect that differences of opinion will creep in.

Some tests were made for the purpose of determining as to the practical limits of compression, using a motor with dimensions as follows:

DIMENSIONS OF MOTOR USED FOR TEST PURPOSES.

Bore.	Stroke.	H.P. (actual).
4 1-2	5 1-2	32.2

The compression was changed from a maximum of 95 pounds per square inch (absolute) down to 75 pounds per square inch (absolute) without altering the speed that the car was able to make, on a hard level road, with all the other conditions maintained, as nearly as possible, constant. The compression changes were by five pound increments, so that little, if anything, was taken for granted and the observations were carefully made.

What these tests indicated were that losses due to high compression made such inroads on the gains that the net result failed to show any advantage such as would warrant one in accepting the disadvantages. The disadvantages are by way of reduced flexibility, knocking under certain well defined road conditions and far higher depreciation, due to greater strains that will abound in the members that must take the shock. A practical demonstration does not prove everything, but it is worth taking into account and in the light of cold experience this question of compression reaches a limit and if account is taken of the service to be rendered and the happenings in view of service, it may be that the discussion can be simplified and the limit may be placed. In the first place, both from the point of view of abstract theory

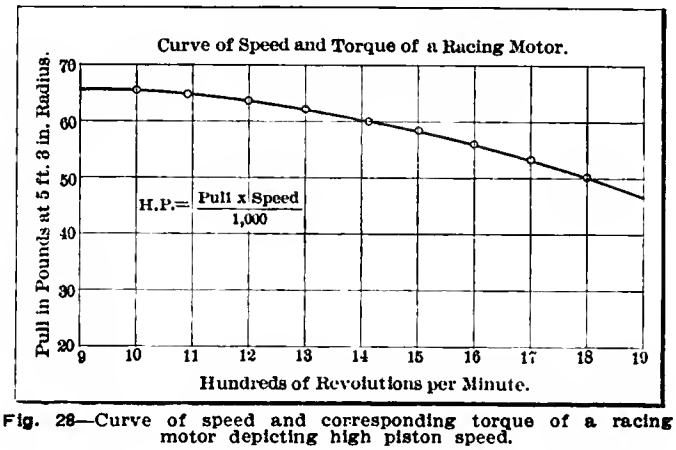

Fig. 28—Curve of speed and corresponding torque of a racing motor depicting high piston speed.

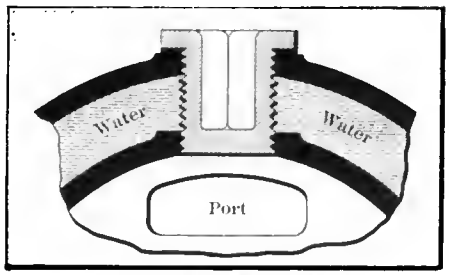

Fig. 29—Section showing defective cylinder plug allowing water to enter combustion chamber.

and in practice, it is mean effective pressure that is sought (on the power stroke) with the minimum of losses on the suction and exhaust strokes. There is no gainsaying the contention that the losses follow increasing compression (on the compression stroke) and unfortunately *the mean effective pressure is not increased in direct proportion to the increase in compression.*

While it is true that power is lost during the compression stroke, it is equally a fact that power may be gained during the exhaust stroke (indirectly) due to increased compression if the speed can be increased and if the mean effective pressure does not decrease as a result of the conditions that increasing speed may dictate. It has been found in practice that with large valves, high compression and balanced forces, due to good mechanical design and construction, the speed can be very high indeed without suffering a loss of mean effective pressure, so that the power (in such motors) increases directly as the speed up to even 2,000 feet per minute of piston travel, which is double that taken as a basis of the accepted formula.

The accepted formula for horsepower in motors of the conventional (automobile) design is as follows:

Let

$H.P.$ = brake-horsepower of the motor,

d = diameter of the bore of the cylinders in inches,

n = number of cylinders (four-cycle),

k = a constant taken on a basis of 1,000 feet per minute for the piston speed and agreed upon as 2.5.

When

$$H.P. = \frac{d^2n}{k} = \frac{d^2n}{2.5}$$

Obviously, at a constant torque, which would be assured were the mean effective pressure to remain a constant, doubling the speed of a motor, which would double the piston travel, would also double the power of the motor. In any attempt to discriminate, then, having in mind the best compression, the mechanical limitations must be uppermost. Having fixed such limits, the area of valves must be taken into account and then it will be proper to estimate the extent to which compression may be increased, having in mind the fuel characteristics. True, the question of cooling and all the other details will have to be favorable, and when everything else is taken into account, the road conditions will have to be kept before the mind's eye.

Of course, a racing car in the hands of a very skilled driver can have many things in its makeup that would scarcely be desirable in a car to be used by an average driver let alone men who know nothing about mechanics and whose minds are not of a mechanical bent. In fixing the compression, then, account must be taken of the service to be rendered and cars may well be divided into classes as follows: (a) Pleasure vehicles in the hands of owners who may not excel in mechanical skill, (b) pleasure vehicles to be driven by professional chauffeurs, (c) taxicahs, (d) commercial cars in general, (e) racing and speed cars.

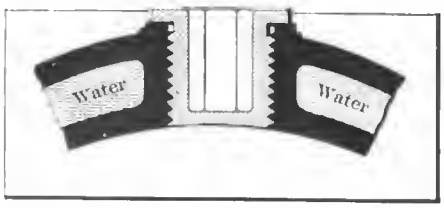

Fig. 30.—More perfect design with enough thread on plug to abort stripping.

If increasing compression demands increasing skill to match, as it does, beyond a certain point, the compression should be a maximum in racing cars, somewhat less for chauffeurs, a good mean for owners of pleasure cars and the minimum for taxicabs and commercial vehicles. This grading is on the assumption that it is good practice to sacrifice power to simplicity in proportion as simplicity taken on a commercial value. Then, there is the question of the inroads that increasing compression will make on the net average result, as for illustration the performance of a car on a level hard road will be better than on a grade considering high compression. But this is another way of talking about the power curve (curve of torque) under different conditions of speed. When a motor is rotating at a high rate of speed as will be possible if the car is going on a hard level road, the effect of leakage of compression is minimized and losses to the water-jacket will be the least. As a result the compression pressure will be a maximum and it follows that the combustion pressure will be a maximum also. If so the chances of maximum power are good if the design of the motor is consistent and the strength of parts is adequate.

On a grade if motors slow down the losses due to leakage of compression will be a maximum and the water-jacket will absorb more heat so that the combustion pressure will be lowered, and to compensate for this the driver is nearly sure to adjust the relation of diluting air to gasoline in favor of an over-rich mixture. The motor will then heat up, power will reduce and the end will be knocking, especially toward the end of a long up-hill drive.

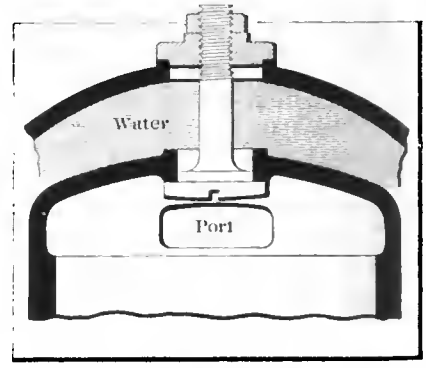

Fig. 31—Instead of a plug, covers are used, allowing water to reach all surfaces.

Knocking on a long grade may be due to increasing compression, attending decreasing speed, coupled with increasing heat, following a diminishing cooling effect, resultant of the influence of gradient in that the power requirement is a maximum. Under such conditions pre-ignition will be the most likely cause of the knocking, hut a small flywheel can influence the situation to a vast extent. Racing motors may be deliberately designed for the conditions such as will assure pre-ignition if on a grade of some length the power requirement is enough to lower the speed of the motor, thus increasing the compression and the heat, as above referred to.

The best way perhaps to illustrate this point is to show a curve of torque under several conditions of speed, using just such a curve as was furnished by a racing motor. Fig. 28 is offered for the purpose, and as will be observed, the best power came at a speed approximating 1,800 revolutions per minute, and since the motor was a four-cylinder, 150-millimeter (square), it follows that the piston travel was:

$$F = \frac{150}{25.4 \times 12} \times 1{,}800 \times 2 = 1{,}769.76 \text{ feet per minute}$$

The curve, Fig. 28, shows that the pull in pounds at 1,800 revolutions per minute of the motor was 50 pounds, and since the length of the lever arm of the prony brake (of the balanced type) was 5 feet 3 inches, it follows that the power of the motor was:

$$H.P. = \frac{50 \times 1{,}800}{1{,}000} = 90 \text{ horsepower.}$$

The torque of this motor increased with decreasing speed. which is the real matter of the moment, which increase was from 50 to 66 pounds, and the latter figure was noted at 1,000 revolutions per minute. Below this speed the torque fell away. due to leakage, effect of the water-jacket, etc., and it is a plain

deduction that pre-ignition would take place at 1,000 revolutions per minute, which speed would be that due to an overlead on a long up-grade, coupled with increasing heat. This would not of necessity be so were the motor of a low compression character considering the performance at the higher speed. In this case the compression was high at the high speed, which would be a fair indication in that the torque was equal to

$T = 50 \times 5.25 = 262.5$ pounds pull at 1-foot radius.

The mean effective pressure (*M.E.P.*) was:

$$M.E.P. = \frac{90 \times 33{,}000}{(5.905^2 \times 0.7854) \times 1{,}769.6} = 63.3 \text{ pounds per}$$

square inch, corresponding to brake-horsepower.

When

90 = horsepower (actual),

33,000 = foot-pounds per minute for 1 horsepower,

5.905 = bore of cylinder in inches,

0.7854 = $\pi/4$,

1,769.6 = piston travel in feet per minute.

The formula as above gives the *M.E.P.* that is directly assignable to the actual horsepower of the motor, to which must be added such a percentage as will equal to losses in the motor from a mechanical standpoint. If, in a motor of this sort, considering the high speed, the losses are taken as equal to 25 per cent., the real *ME.P.* would have to be:

$$M.E.P. = \frac{63.3}{0.75} = 84.4 \text{ pounds per square inch.}$$

This phase of the subject is pursued to the extent necessary to bring out the fact that compression must be that which will afford the desired results considering the class of service to be performed by a motor, and it is plain that in a certain class of work it is even an advantage to court pre-ignition. In general service, however, it would be the height of fallacy to design for high compression rather than for acceptable speed, and on the whole it is the right course to consider the speed, such as the motor will thrive under, and fix the fuel compression to conform to the requirements.

Water in Cylinders Makes for Trouble.—Frequently it is found that water passes into cylinders through defects in castings in which slag is enmeshed or due to misplaced cores. In one case that came prominently to the notice of the author a large number of cylinders were so designed that the plug in the cylinder heads failed to satisfy the requirements and water found its way into the cylinders as a result. The defective design is illustrated in Fig. 29 and it will be observed that a plug (bronze) was screwed in, forming the connecting link between the inner and the jacket domes. In service due to differences in heat the thread on the plug stripped at the inner dome and water readily passed into the cylinders.

This problem is serious even when the cylinders are properly designed, but there is small chance of being able to realize much satisfaction from a motor designed to include the construction as depicted in Fig. 29. Since this is a problem involving the mixture, rather than cooling, it is believed to be proper to discuss it under this head. Fig. 30 shows a modification of the defective plan as indicated in Fig. 29. The plug is screw in all the way and the inner and outer walls of the dome are joined. This is probably a better form of dome than the other, yet even so, it is far from perfect, since it fails to take into account the considerable differences in temperature that must abound at this point in cylinders and the resultant strains.

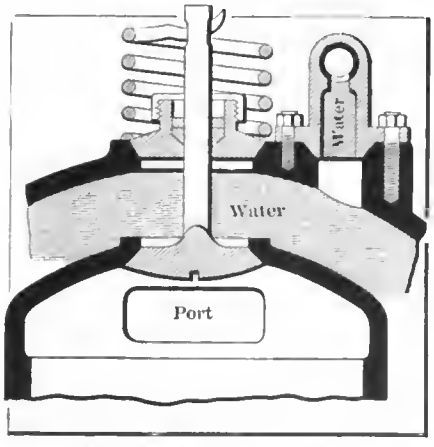

Fig. 32—Differences in expansion compensated for by using springs to hold covers in place.

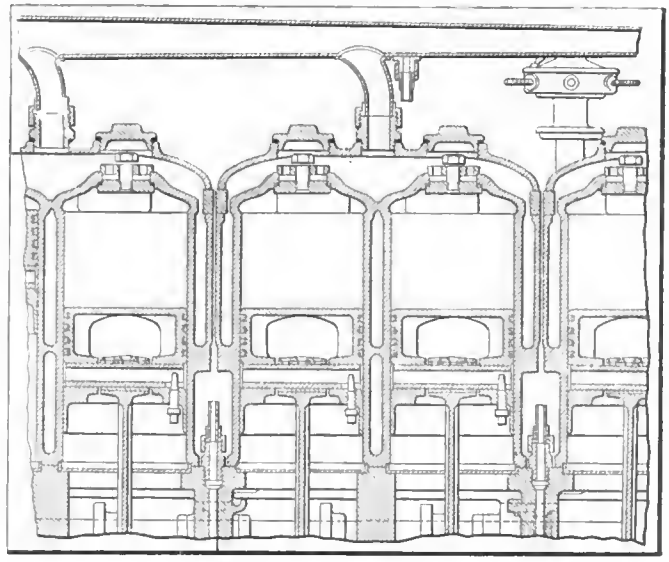

Fig. 33—Section of a Pierce motor showing correct method of providing differences in expansion.

Still another way to close up the head of cylinders is shown in Fig. 31, many of which have been used, and when the work is well executed this form of cap holds tight to a very satisfactory extent. In this form, as the illustration depicts, a flat-seated, valve-like structure is employed, and a cap is screwed down on the stem to cover the water dome with a nut outside, which is used to tighten the device sufficiently to spring the water dome toward the inner dome, thus bringing a considerable amount of work on the stem. If the stem is not of good material and of adequate section the end will be a leak to the combustion chamber due to elongation of the stem. In this case all joints are ground to a tight fit and once the cylinder is rendered tight if the stem is strong enough to stand the strain the job becomes permanent and tight.

Fig. 32 represents a theory involving the differences due to heat changes, in which the inner and the outer caps are held to their respective seats by means of a strong spring. In this case the stem is not subjected to the strains due to heat, but have to sustain against the pressure of the spring only. The seats are all at an angle of 45 degrees to be ground tight the same as a valve as used in the conventional way.

An excellent plan that works out well in practice and is used on motors of reputation is the one depicted in Fig. 33. In this case the dome of the combustion chamber is absolutely separated from the dome of the water-jacket, and means are provided to maintain each of the covers as tight as the occasion requires, in such a way as to assure entire freedom from all the ills of heat changes. As will be observed, water contacts with the cover over the combustion chamber, and in this way, all the heated surfaces are adequately cooled. The scheme is not complicated, and the cost of doing the work in this way is no bar to its use. The cylinders are cast in pairs, with separate dividing walls, and unequal expansion, which is likely to lead to leakage, with consequent loss of compression, is done away with.

This phase of the subject cannot well be concluded unless to point out that any defect which will let water in will allow the combustion products to escape, and it is a self-evident proposition that the combustion products, if they get into the water system, will soon make an outlet at the expense of the system. The author witnessed just such a case, and the bottom of the water tank was blown out by the force of accumulated pressure thus precluding a road repair.

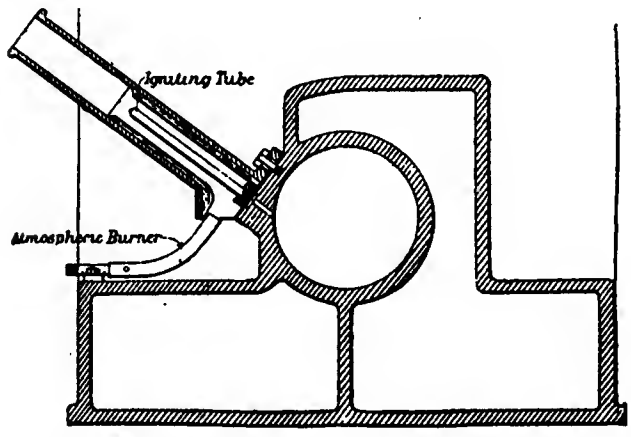
(To be continued.)

Helpful Hints on Ignition Topics

By Morris A. Hall

THE subject of ignition is one about which much of mystery and secrecy lingers, hence it is a very deep question for the ordinary driver to go into. As an aid to the man learning to drive his own car, and desirous of learning a little something about its component parts, a few of the more important parts of the ignition system will be taken up and explained.

There are in general use two methods of igniting the charge in the cylinder of an engine of the internal combustion type. These are the mechanical and the electrical processes. The former being the least important will be mentioned first.



Section Through Typical Hot Tube Igniter.

It has of itself, two forms, the hot ball and the hot tube. The hot ball takes the form of a ball-shaped piece of metal projecting into the cylinder or closely connected with it. This is intended to be heated by the operation of the engine, and when so heated, gives its heat to igniting the next charge drawn in. So the action is in the nature of a preignition, but the location of the mass of metal is so chosen that the firing of the charge does not take place until the crank has so nearly approached center that a backfire will not take place. To start the engine in the first instance, it is necessary to heat the ball or mass of metal from the exterior, by means of a torch. This takes some time and so the process of starting is an extended one. As a result, the form of ignition is not a popular one, in fact, it is only used on a few stationary engines, which require starting but once a day, or at least not frequently.

In the early forms of automobiles, the hot tube was used extensively, as on the Daimler and the early French collaborators of his time. It consists essentially of an endless or blind tube of platinum or platinum and porcelain combined, which was heated by means of a small and independent flame. This flame is fed through a separate pipe leading to it from the gasoline tank. The heated tube ignites the charge in a somewhat similar manner to the hot ball, with this exception, in some cases, the hot tube is put into and out of communication with the working cylinder by means of a sliding or rotating valve. The latter amplification of this indirect method did much to regulate and improve the method as a whole. It had, however, a number of fundamental drawbacks, which no improvements could eliminate, and it languished. Obstacles to its success were:

(1) It will cause premature ignition when the heated portion is too near the cylinder, and the rest of the tube is clogged with burned or exhaust gas.

(2) It will cause misfiring when it becomes filled with burned gas, which prevents the fresh fuel in the cylinder coming into contact with the incandescent walls.

(3) It may cause difficulty and possibly misfiring when the wind catches the flame and deflects it from the tube, which then becomes cold and unable to fire the charge.

(4) It may cause trouble through the derangement of or accident to parts of it, as cracked tubes, loose or faulty burners, or deficient fuel supply to the burner.

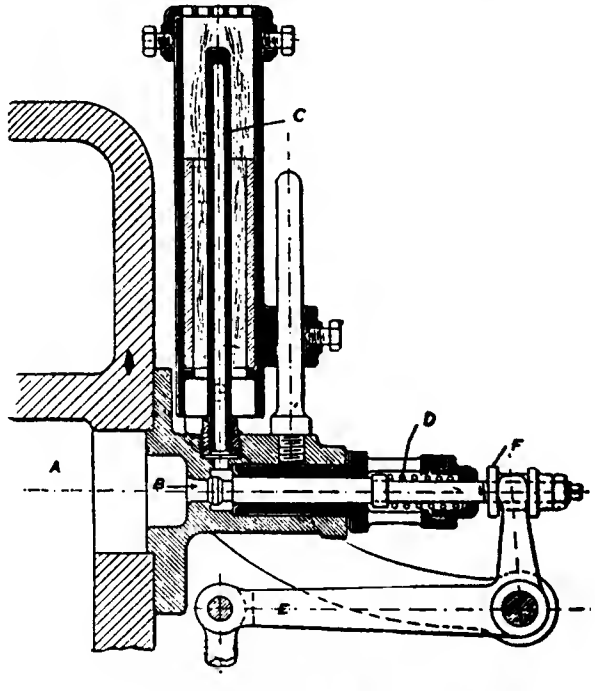
As against all these sources of trouble, the advantages were not numerous enough nor strong enough to save the day.

Self-Ignition by the Heat of Compression.—A secondary method of firing the charge has some of the features of the mechanical way, but in this the fuel is not admitted in the ordinary manner. It is sprayed in at the close of the compression stroke, this acting to compress air only. The act of reducing the volume of the air to a very small quantity increases its temperature to a very high figure. So when the fuel enters, in the form of a spray, it is instantly ignited by the highly heated air and burns rather than explodes.

TABLE I.—Variation of Volume and Temperature with Compression.

Gauge Pressure.	Volume.	Temperature.
0	1.000	60
2	.910	80.4
5	.810	106
10	.690	145
20	.543	207
30	.454	252
40	.393	302
50	.350	339
75	.276	420
100	.232	485
115	.213	518
130	.197	550
145	.184	580
160	.172	607
175	.163	632
200	.149	672

This method is not in general use, in fact, it is confined to a single maker, although of late some interest has been aroused in the subject of fuel injection, which carries with it the other



Hot Tube with Mechanical Timing Valve.

matter of self-ignition. The great simplification which it allows will doubtless bring it into favor before long, despite the constructive difficulties.

So, too, catalytic ignition comes really in the same class as the hot-tube method, the main difference being that the heat of compression heats the spongy platinum, which in turn, by catalytic action fires the charge. Like the hot tube, it cannot be closely controlled, but, on the other hand, it has no parts to get out of order and cause trouble.

Electric Ignition Much More General.—All of which leads up to electric ignition, the form in general use, one might almost say in exclusive use, to-day. As with each of the other forms previously mentioned, this type is subject to several subdivisions. The first is into:

(a) Primary electric ignition, and (b) secondary electric ignition.

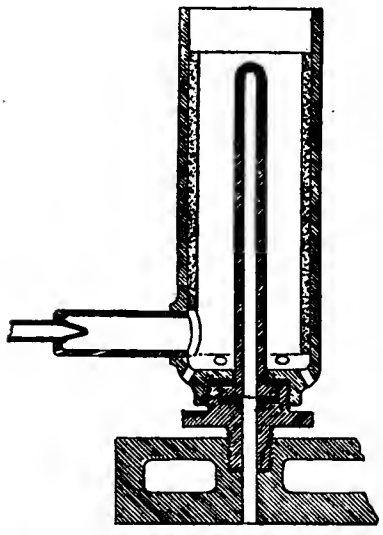
In the common parlance, these are called low tension and high tension, the former being given the additional name of the make-and-break system, while the latter is more often called the jump-spark system. The latter is, moreover, subdivided again according to the source of current, although for sparking purposes, all sources are alike. These are:

(a-1) Dry cells.

(a-2) Storage batteries.

(a-3) Magnetos or generators.

(a-4) Small dynamos and all other sources of current.



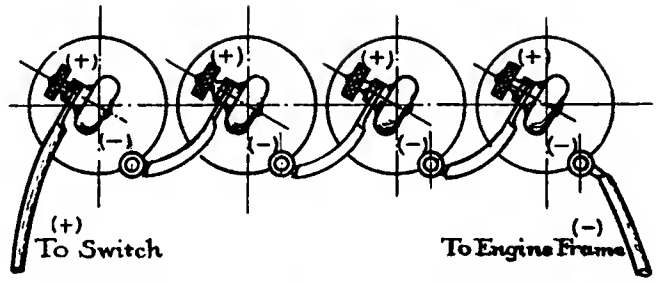
Porcelain Lining Has a Long Life.

The first, or dry cells, are very generally used on moderate and low-priced cars. They are simple in construction, comparatively simple in operation. and their action is easy to understand. Each cell is composed of three elements: The carbon, the zinc, and the electrolyte. The carbon usually takes the form of a round stick placed in the center of a cylindrical vessel made of zinc in sheet form. The space between the carbon and the zinc is filled with the electrolyte, generally a solution of sal-ammoniac, which is poured in on crushed coke. The top is closed or rather sealed with pitch to prevent the loss or evaporation of the liquid. Through this, project the ends of the carbon and the zinc, these being formed into binding posts for holding the wires. As this holding of the wires must be an intimate relation, the usual form is a threaded shank upon which a pair of nuts are mounted. Between these the wire to be connected is crushed or compressed by the moving together of the nuts.

The two poles or binding posts are called the positive and the negative, and are indicated by the + sign for the former and the — sign for the other. Carbon being the positive element, the + sign attaches to it. Now, the act of connecting these terminals together so as to allow a flow of current allows of two different methods of procedure, a right and a wrong way, it is true, but that was not what was meant.

The Two Forms of Battery Connections.—The idea intended was that by varying the mode of connecting the terminals, in one or the other of two ways, the output of the cells may be increased. These two ways are called series connection and multiple or parallel connection. To connect dry batteries in series, the terminals are joined alternately, that is, the zinc of the first is connected to the carbon of the second, the zinc of the second to the carbon of the third, etc.

When so joined, the positive element is left free at one end, and forms the positive terminal of the group, which is then



The Ordinary Battery Connection, in Series.

considered as a unit. Similarly, the other free end, the negative, forms the negative terminal of the unit. In this method of connection, the resulting current is the sum of the voltage of all of the cells comprising the group, or expressed otherwise, is the product of the voltage of a single cell times the number of cells. The figure shows how four ordinary small dry batteries are connected in series, which is the ordinary connection.

The other form of connection, the parallel or multiple, differs from the one just given in that the similar terminals are joined together, that is, all of the positives are on one wire. Likewise, all of the negatives are on the other wire. This mode of wiring up the cells gives a smaller output for the group. Thus if the individual batteries have an internal resistance which is low in comparison with the external resistance, the total output will be but slightly more than that of a single cell. If, on the other hand, the internal resistance is high relative to the external, the current will be roughly proportional to the number of cells.

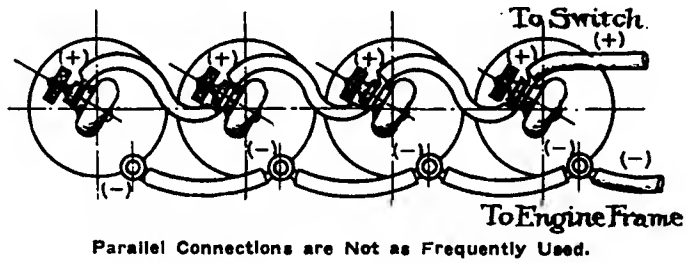
The former is the case so much more than the latter, that it has come to be regarded as a truism that the current from a parallel connection is that of a single cell. A diagram is shown of a set of four dry batteries connected in multiple.

Where the cells are divided into sets or groups of a small number (four is usual), and more than one of these sets are used at a time, there are again two methods of joining them. These two are the same as before, viz., series and multiple. The former is very seldom used, if ever, but the other is rather common. When two or more sets of batteries, themselves connected in series are, as sets, joined in multiple, the whole is spoken of as connected in series-multiple.

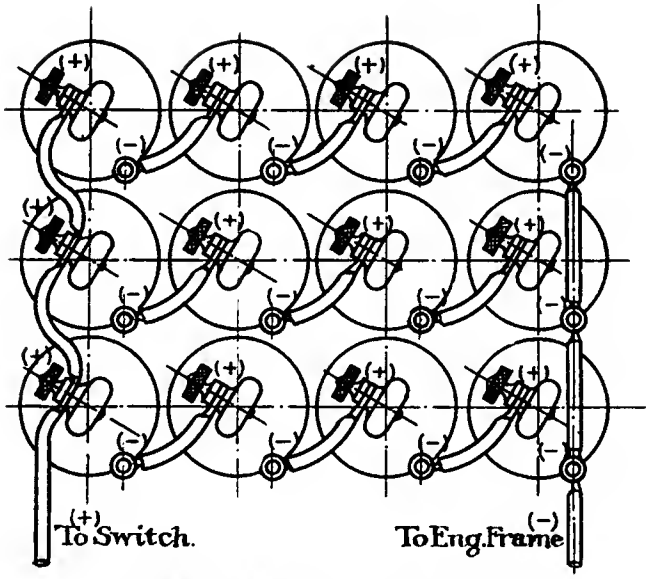
The output from the composite group of many cells is no greater than from any one of the series-connected sets composing it. Usually the voltage of a dry cell is 1 1-4 volts. In multiple, four cells will still give 1 1-4 volts, but in series, the same four will produce 4 x 1 1-4 = 5 volts. In series-multiple, on the other hand, two, three or more sets of cells of four each will still give but 5 volts. Where then does the advantage of this connection come in, if there is any?

Multiple Series Advantages.—There are a number of advantages of this method, their weight being sufficient to more than overbalance the extra first cost, increased number of connections, and other so-called advantages of the use of the smaller number of batteries connected up in series, so as to produce an equivalent voltage output.

First, there is the greater length of life of the individual cells. To obviate the greater cost (say with twice as many cells it is just twice), the service must last at least twice as long. In fact, it does even better than this. Where four in series lasted but 20 hours, two sets of four each in multiple series lasted 70 hours, which is more than three times as much.



Parallel Connections are Not as Frequently Used.



Three Sets of Cells Connected in Series Multiple.

Second, the cost per hour, mile, or on any unit basis decreases with the number of sets combined in the series-multiple arrangement, for the reason that the working life is greater. If batteries cost the same each, and a connection of eight, in sets of fours, gives a life of three and a half that of the four used alone, it is at once apparent that the cost of service per unit, whatever that unit may be, is reduced to two times one over three and a half, or 4|7.

Third, in common with the two economies of current and consequent cost, as mentioned above, the life of dry cells being carried out to such a great extent, the driver's worry about the state or condition of his ignition current is reduced to a minimum. Given a sufficient number of cells, connected in this manner, it is possible to go through an ordinary season's running without giving the batteries a thought.

The fundamental difference between the dry cell and the wet or storage battery is that one is reversible while the other is not. Although both are chemical actions, that of the dry battery only works in one direction, so that the cell can only give out current until exhausted, after which it must be thrown away and new cells purchased. This is the point which makes the question of the life of dry batteries so important.

In the case of storage batteries, on the other hand, the matter of length of life is not of such grave importance, because the chemical action is a reversible one. So, when the cell has become exhausted and current no longer passes, it is possible to send a current through it, when the reverse action takes place and builds up the drained plates to a point where they are again self-sufficient and able to give off current.

Storage Cells Are More Popular.—For some strange reason, the storage, or, as it is sometimes called, the secondary battery, is more popular than is the very simple dry cell.

The ordinary storage battery is made with lead plates. These may be of two or three kinds, all of which are in daily use. The amalgamated plate has the surface of the lead coated with mercury, which then unites with the lead in such a way that any impurities present in the lead itself are covered while the lead united with the mercury in the form of amalgam is continually presented. The surface presented to the electrolyte is thus always that of pure material, and consequently the chemical action is sustained with equal force right down to the limit of the amount of metal in the plate.

Then there is the pasted plate, so-called because the surface presented to the fluid is composed of material in the form of paste, which has been added to the skeleton form of the grid. This paste is of two kinds, yellow oxide of lead, known as litharge, which is pasted to the negative plates, and red oxide of lead, called minimum, pasted to the positive plate. The shape of the grid to which the paste is added, varies greatly.

BORNE IN THESE DAYS WITH AUTO'S RISING TIDE

New Design for an Auto Funeral Car.—An adaptation of an automobile into a funeral car with new features has been patented by J. W. Butler, F. R. Briggs and E. G. Clarke, of Cleveland. In appearance it is unlike that of the usual funeral conveyance, differing only in size from the lines of a standard limousine, but large enough to displace the hearse and five carriages. On the way to a cemetery it is divided into two compartments by a partition, and in inclement weather this may be collapsed and the coach used as a chapel in which to conduct the service at the grave. The inventors have formed the Auto Funeral Car Company, Inc., and will shortly begin the production of the cars.

Dairymen and the Automobile.—At the recent convention in Chicago of dairymen from five States a remarkable situation in respect to the use of automobiles was revealed. Of those attending, 112 were asked as to the use and value of autos to them. It appeared that 38 owned autos, and 11 had more than one machine, mostly used to transport products, but several so equipped that they can operate separators, churns, etc. One runs a bottle washer and another pumps water to flush the dairy barn. Reports showed a steadily increasing interest in automobiles and good roads.

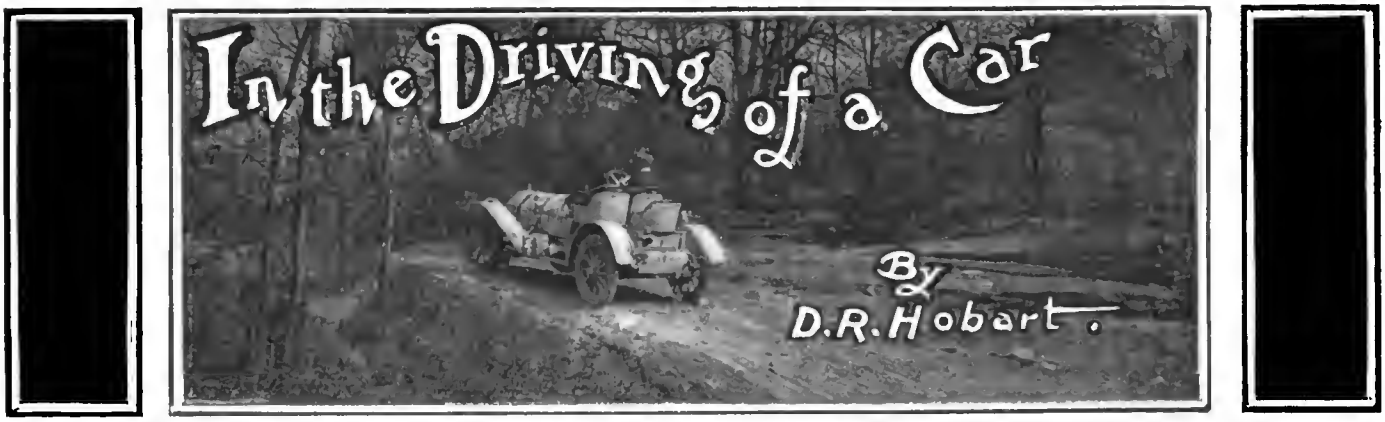
Voters Carried Wholesale to the Polls.—Automobiles have been valued adjuncts to political parties on election days in many parts of the country, the latest section to use them extensively being South Orange, N. J. At the recent election of the Board of Village Trustees 200 cars were pressed into service, and by means of them not a single voter was allowed to go to his place of business until he had cast a ballot.

Combines Duties of Clergyman and Auto Agent.—Rev. Harrison F. Miller, a bookbinder by trade, who resigned from the pastorate of the Chardon, Ohio, Disciple Church recently, has taken the agency for an automobile in that town, and intends to interweave his multitudinous callings. Mr. Miller states that he will not abandon the performance of his ministerial duties, and that in his mercenary pursuits with his touring cars he will be able to have a wider range of influence as a clergyman than ever before.

London Autos with Consciences.—To prevent undue speeding the police of London are contemplating a novel method of procedure, whereby the automobiles will loudly proclaim their movements. Taxicabs and omnibuses may be fitted with whistles, sealed so that they cannot be tampered with, which will be set to give a continuous warning as long as the machines travel at above a certain rate of speed. Thus the conscience of the driver will have more than moral support from his conveyance.

Noted Whip Sells Horses and Buys Autos.—Because automobiles are so numerous that he finds it uncomfortable to drive horses, former Mayor Welling G. Sickel, of Trenton, N. J., one of the most noted whips in the State, has sold his entire string of thoroughbreds, riding, and tally-ho horses. Of course his stables will be turned into a garage.

Trades Auto for House and Lot.—From Salisbury, N. C., comes the latest report of a novel exchange to secure an automobile. Robert Lowder, of Albemarle, wanted a touring car, and J. D. Kennerly, of Salisbury, wanted a house and lot, so the latter gave his $3,000 touring car to the former in exchange.



PRONOUNCEDLY prominent are two faults among those possessed by automobilists, and to these must be credited the majority of accidents for which the driver of the car is responsible. The first is that of overconfidence, the average driver considering himself a finished performer as soon as he is able to steer a car with any degree of certainty, and to vary his speed as desired without injuring the machine. As a matter of fact, he is just beginning to qualify as a driver at this stage of the game, as it is only then that he can really give his attention to the road and the conditions of traffic. It is at this stage that the greatest risks are taken, through ignorance in most cases, and even with the knowledge that the chances are greatly against him the overconfident autoist will fly past cross-roads and dodge in between moving trolley cars on slippery rails "on the chance." It has been said that a good scare is the best instructor in wisdom in driving locomotives, and this is true also with regard to automobiles. Once an autoist has run into some other vehicle or been forced to take the ditch to avoid being smashed by a train, he will be more careful about making turns and negotiating railroad crossings in the future. However, the knowledge of driving need not be so acquired, but can be gotten by experience on the road and by avoiding unnecessary risks at all times.

The Fault of "Showy" Driving.—The second fault is that of "showy" driving. A large number of autoists commit this error in taking corners at high speed on two wheels, cutting in in front of another car for the sake of taking a turn ahead of it, coming up to the stopping point at speed and setting the brakes on hard, and similar performances, imagining that such driving shows their skill and causes them to be greatly admired or envied. As a matter of fact, they are not envied nor admired, except, perhaps, for their luck in escaping destruction, but disliked for their lack of consideration for others and because of the danger which they constitute to all road users. Like the overconfident autoist, the showy driver takes crossings at speed, but does so with the full knowledge of what may happen, and is proud of the fact. That driving of this kind is unsafe is shown by the hospital reports, and that it is costly, by the size of the repair and tire bills. A few more plaudits are gained, but when the year's account is footed up the hurrahs come high.

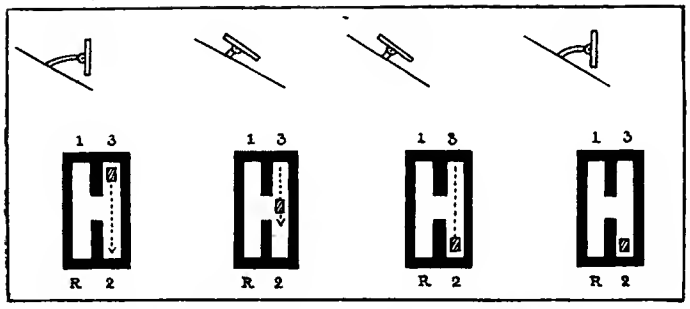
The Question of Speed.—How fast one can travel with safety is a question that each must find out for himself. There are autoists who can drive safely and carefully at the highest speed at which the car can keep on the road, and others who cannot drive five miles an hour with safety. If an autoist is in doubt as to his own maximum safe speed, he would do well to figure it at the limit set down by the laws of the State in which he resides. As this limit is calculated for the majority of autoists in the State, the autoist can be satisfied that it is safe for him to travel at the legal speed, and by not exceeding it, he will be exempt from arrest for fast driving.

An excellent reason for not driving at speed is the discomfort experienced by the passengers on the rear seats, who are bounced about at every inequality of the road, even on cars with long wheelbases. If any autoist should doubt this, let him occupy one of the seats in the tonneau of a fast-driven automobile for several hours and he will be thoroughly convinced. Another reason is the heavy strains to which the machine is subjected at speed tend to shorten its useful life and bring it to the repair shop sooner than necessary.

General Principles to Follow.—When on the open road, away from cities or towns, the following rule should be borne in mind: Drive with moderate speed on the level, slow speed down hill and wide-open throttle for hill climbing or getting up speed only. The condition of the road should be noted, the presence of mud or dust thereon furnishing a sufficient reason for slowing down somewhat for the sake of other road users, and grease, roughness or excessive camber for the sake of the car and its occupants. The ordinary rules of the road regarding the negotiation of turns and crossings and the overtaking or passing of other vehicles should be adhered to even though a lower rate of speed is involved. A sharp lookout should always be kept for traffic of all kinds as well as on approaching schools, churches or public buildings and also for road signs indicating danger, caution, etc. When on the road the autoist should show the same courtesy to other road users as he would if he met them on a city street. Courtesy is much appreciated in autoists and goes a long way toward removing the prejudice against automobiles which exists in many places at present.

Brakes and Their Proper Use.—Next to the motive power in importance come the brakes. There are a number of things that every autoist should know and remember about them, and the first and most important is that brakes vary in their effectiveness from time to time and that the difference between safey and disaster depends on their being kept in good condition and properly adjusted. Another and scarcely less important point is that while a brake may be perfectly satisfactory for slowing down, it by no means follows that it will bring a car to a standstill satisfactorily, nor hold the car from going backward. There is a great temptation to neglect the brakes, both before starting out and when they need setting up on the road, and it is most important that the brakes are tested before starting, and if any adjustment is needed while on the road it should be made at once. The brakes should be tested with the car in motion, the pedal or hand lever being applied until the car slows down and stops. The distance traversed in making this test should be noted and a greater distance allowed in making stops on the road. In applying brakes, the application should be gradual, reducing the speed of the car as quickly as possible, but not locking the wheels. As long as the tires retain their grip on the road, the powerful retarding action of the brakes on the car continues, but when the wheels are locked the brakes have little or no effect and the car will either slide along or skid, in either case being out of control of the driver. If the wheels become locked while descending a hill the brakes should be released until the wheels are again revolving and then reapplied gradually, when they will act satisfactorily.

Proper Procedure in Gear Changing.—In changing gears the autoist should endeavor to have the motor and car moving at nearly corresponding rates of speed before the clutch is engaged. With the planetary type of gear, changing is simple, and



Changing Down from Third to Second Speed.

drivers usually guess at the proper period at which to make the change, any mistake in estimating the rates of the car and motor being of little consequence, as the bands will slip instead of transmitting the shock to the gear. A similar action occurs in the case of individual clutch or friction gears, but with the sliding type severe strains and shocks have to be taken up by the clutch and are usually transmitted in part to the gear if the clutch is not slipped. What applies to the sliding type in general applies to the other types as well.

Changing from a Lower to a Higher Gear.—In changing from a lower to a higher gear it will be necessary to speed up the motor by means of the throttle or accelerator in order to store enough energy in the flywheel to furnish the work needed to accelerate the car to its new speed. As the speed of the car increases the higher gear should be engaged, the autoist not being in too great a hurry to make the change. The movement of the change gear lever should be made quickly in order that the car does not lose way. When changing from a higher to a lower gear the change should be made as quickly as possible before the car has time to slow down. When climbing a steep hill it should be ascended as far as possible on the high gear by proper use of the throttle and spark, and the change down to the lower gear made as soon as the motor begins to labor or is in danger of stopping. The presence of an unusual number of passengers in the car will affect its ability to negotiate grades which ordinarily are taken on the high gear, and the autoist should remember this and not attempt to force the car to travel on that gear with the increased load, but resort to a lower gear.

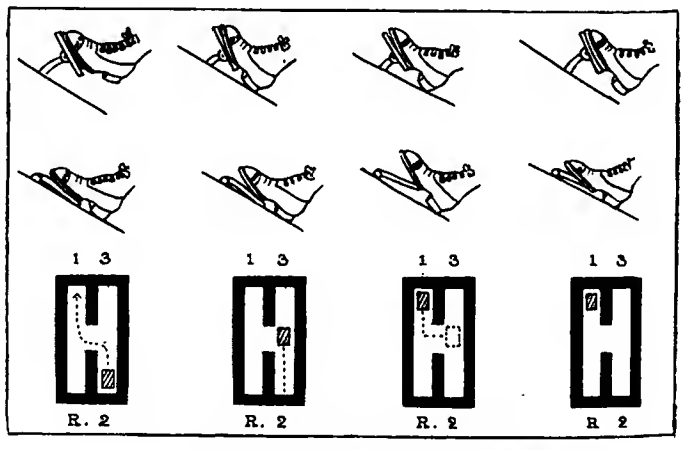
Changing with Selective Gearing.—Of the two chief varieties of sliding gear the selective is in most common use. The most familiar form employs a sort of grid with communication between the two slots through a gate or passage cut in the bar at right angles to the slots. A lever works backward or forward in either of these slots and can be shifted from one to the other through the communicating gate. The ends of the slots represent the positions of the lever when certain gears are engaged, and in the illustration the lever is seen with the third or high gear in mesh. For changing from third to second gear the procedure is shown graphically. The first position is with the clutch engaged and the gear lever in third gear position, the clutch being shown above the grid. The second position shows the clutch disengaged and the lever being moved toward the second gear position marked 2 on the grid. The third shows the lever in second gear position and the fourth, the final step in the change, the clutch again engaged. The procedure is the same in the case of a progressive sliding gear.

Changing from Second to First Gear.—The second figure shows the change from second to first gear on the same grid. The upper line of figures shows the movement of the clutch pedal and the central line the corresponding movement of the accelerator or throttle. The first position shows the clutch in and the throttle open ready for the change. The second shows the clutch withdrawn and the lever moved along the slot until opposite the gate. The third shows the lever being moved through the gate and along the other slot toward the first gear position, this sideways and forward movement being combined in one continuous movement. The motor having speeded up as soon as the clutch is released, it is necessary to reduce its speed somewhat before engaging the second gear, so the accelerator is shown partially released in this position. The gear is then engaged, the clutch let in and the accelerator again depressed, which is the situation shown in the fourth position. A change from first to second is made in the reverse order, except that the accelerator pedal is not released unless it is necessary.

Use of the Spark.—Upon the proper use of the sparking device depends the economy of the motor, and in many cases the safety of the driver. On some cars the sparking point on the magneto is fixed, and the autoist controls the car by the throttle only. There are a number of cars in use which employ the battery in connection with separate coils or a single spark system, or a magneto on which the spark can be regulated by the driver. When starting, the spark should be retarded in the case of battery ignition to prevent backfiring, and slightly advanced to a certain point, depending on the motor and magneto, in the case of magneto ignition. When it is desired to slow the motor down below the point obtained by throtting only, the spark is likewise retarded. In ordinary running, a position of the spark lever can be found which will give fair average results through a considerable range of speed without changing its position, and this position varies with each motor and can be found by experience. When a higher rate of speed is desired, the throttle is opened and the spark advanced gradually. If a grade is to be negotiated it should be "rushed" if possible, the throttle being opened full and the spark well advanced until the motor begins to slow down and "knock," when the spark should be retarded to correct this. The autoist should always keep the spark as far advanced as possible, without causing the motor to knock. When accelerating or retarding the spark should follow the throttle, the latter always being operated first.

Driving at a Constant Speed.—One of the best lessons in the proper method of driving a car is that of driving at a constant speed, no matter what the road conditions. The autoist should previously determine a speed compatible with the nature of all roads over which the car is to pass, and should see that the speedometer hand keeps at the determined speed throughout, regulating the spark and throttle and changing gears if necessary. Considerably more will be learned about the flexibility and power of the motor in driving in this way for a few times in numerous drives in the ordinary way.

Reversing Is Usually Neglected.—Among other things connected with driving which is apt to be neglected is reversing or driving a car backward. Usually a car is never reversed for more than a few yards at a time and the maneuvering involved requires no great skill. Steering a car when running backwards is diametrically opposite to that when running forward. A turn of the wheel to the left steers the car in the opposite direction to the right, and vice versa. The usual mistake made in reversing is in turning the steering wheel too far and describing zigzags in the road as a result. The autoist should remember that the reverse gear of a sliding change gear should never be engaged until the car has been brought to a full stop.



Changing Down from Second to First Speed.

Pointers on the Care of Vehicle Batteries

By Howard Greene

AT least once a week the battery cells should be flushed. That is, clean cold water should be added, if necessary to bring the electrolyte, as the liquid is called, half an inch above the tops of the plates. This should be done before charging, so that water will become thoroughly mixed with the electrolyte. If it is found that an individual cell repeatedly requires considerably more flushing than the others, look carefully for the reason. There may be a slow leak in the jar, in which case there will probably be a wet spot under the cell. Some internal trouble may cause the cell to heat and the water to evaporate more rapidly than from the other cells. In case of a leak, the continued addition of water will bring down the gravity of the sulphuric acid, or whatever liquid is used, and in case of internal heating, the temperature of the cell will give the necessary warning. In either case, the cell should come out and go to the expert.

Care to be Used or Destruction Results.—To continue using a cell that heats, or one that leaks, is to invite the destruction of that cell and delay on the road. This is a continuous performance, that is, the hotter the cell becomes, the more rapid the evaporation, and the lower the level of the electrolyte will fall; the lower the electrolyte falls in the cell, the hotter it will get. The electrolyte soon falls so low that current cannot be forced through, and the vehicle will be brought to a stop. When this occurs, the cell will be found steaming hot, the plates in a sad condition, the separators destroyed and very likely the jar cracked from the heat. A cell that has gone through this experience can be made useful again only by a long course of tender nursing, or it may be completely ruined.

If a jar springs a leak and it is not possible to replace it with a new one for some time, cut the connections to the adjoining cells with a "plumber's saw" and lift the elements from the jar, putting them, if possible, into a vessel of electrolyte or, at least, into clean cold water. Leave the old jar in place as a space filler, or else fill in with a wooden form of the right size and shape. Connect across the space by burning in a lead strap or, if this cannot be done, by a heavy copper wire secured to the strap ends with brass screws and washers. Lose no time in having repairs made. Have the cell fully charged before cutting it out. If the elements are placed in electrolyte, put the fluid in a glass, wood or hard rubber vessel, as the acid has a vigorous corrosive action on metals other than lead. In any case, make sure that there is no metallic connection between the plates.

Beware of Loose Connections.—A loose or imperfect connection anywhere about the battery is apt to cause trouble which may become serious. The resistance established thereby to the passage of the current causes the loss of just so much energy, and, furthermore, the overcoming of the resistance is accompanied by heat. If the resistance is sufficient, the heat may become so great as to cause the fusion of the conductor at the faulty contact. The heating power of the current, from even a moderate sized vehicle battery, is surprising to one unfamiliar with such matters. A film of oil, between surfaces that should be in contact, can do damage very quickly. The heat carbonizes the oil and the carbon grows extremely hot until finally the metal melts when a heavy current passes. Consequently, one should see that all separable connections are kept clean and bright at the contact surfaces.

Look Out for Local Short Circuits.—If a strap breaks while the battery is delivering a heavy current, it is possible that there may be fusion of the lead at the point of fracture, and that particles of the loose metal may fall into the bottom of the cell and cause local short-circuiting and heating. This possibility should be taken into consideration if a cell which previously gave no trouble shows a tendency to heat after a broken connecting strap has been re-burned. It is also possible that a careless burner may have allowed lead scrapings or particles of molten lead to fall among the plates, with the same result. Such carelessness is, of course, inexcusable.

A very low temperature—below freezing—will reduce the capacity of the battery and also its voltage, although both will recover as the temperature rises and there will be no permanent damage. The battery should be kept, when not on the road, in a place where the temperature does not fall very low. The temperature at which a battery works best is about the same as that most comfortable for the driver.

In course of time the active material in the plates becomes disintegrated and falls to the bottom of the jars. If allowed to continue long enough, the deposited paste or free metal would reach the bottom edges of the plates, which are sometimes supported on ribs rising from the floors of the pars on purpose to keep them clear of this sediment. When there is only a quarter of an inch between the top of sediment and the bottom of plates, the jars must be cleaned. In order to ascertain when it will be necessary to clean a battery, one pair of straps is disconnected and the plates lifted out of the jar, permitting the depth of the deposit to be measured, after the battery has been charged, say, 50 times, or has worked 50 days. Suppose the ribs are 1¾ inches and there is sediment of half an inch.

Rate of Deposition Indicates Time for Cleaning.—Clearly at the same rate the sediment would be 1½ inches deep, or within a quarter of an inch of the plates, after 100 more charges; but, as the plates grow older the rate increases, and it is usual to allow for a 20 per cent. increase. This would make it necessary to clean the battery after a total of 120 charges—50 before examination of the single cell and 70 after ward. The cleaning should be done by an expert, who will at the same time examine the whole battery carefully and take the opportunity to do whatever other work is necessary.

Every precaution should be taken to prevent dust, dirt or foreign matter of any kind from getting into the cells. When in place in the vehicle the battery should be thoroughly protected from rain and snow, or there will be, perhaps, a weakening of the electrolyte that will be difficult to account for. Keep the exterior of the battery as clean and dry as possible, and the trouble will be well repaid.

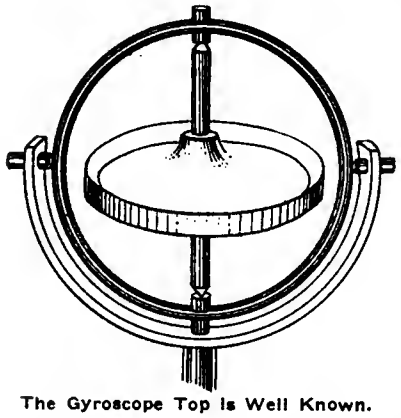
Electrolyte will burn its way rapidly through cloth, and one may as well say farewell to any clothes used when working steadily about batteries. If acid is splashed on clothes that are wanted for further use, put ammonia, sal soda and water—or, if these are not at hand, plenty of clean cold water—on the places and disaster will be acerted. Acid will make the skin of the hands dry and harsh; the remedy is to wash them in glycerine in the evening. If the acid gets into a cut or scratch, it will instantly make its presence felt by the sharp stinging that will follow. Cold water will stop this at once.

In conclusion, it may be emphasized that it is not worth while, even from the point of view of a lazy man, to postpone giving to a battery the attention it requires. The trouble will wait, and very likely will improve the time by multiplying itself, so that an hour saved this week may stretch out until it becomes a day's work next time. The effect on the owner's pocket may be even more marked, for time is money, and money spent for repairs, that could just as well have been avoided without expense, makes a great deal of noise sometimes.

The Flywheel as a Gyroscope

By Henry M. Russell, Jr.

NUMEROUS opinions have been expressed from time to time on the gyroscopic action of the fly-wheel of an automobile and various advantages are claimed for certain cars in which the fly-wheel is placed in an unusual position. In claiming these advantages, comparison is made with the Schlick gyroscope to prevent rolling in vessels and the Brennen mono-rail car. In these comparisons the fact has apparently been lost sight of that the conditions upon which the operation of the last named devices depend do not exist in an ordinary automobile.



The Gyroscope Top is Well Known.

If we attempt to rotate the axis of a rotating fly-wheel in one plane, the axis will tend to rotate in another plane at right angles to the first. If the axis is free to rotate in the second plane it will do so and the force applied will be expended in producing this rotation, and no rotation will be produced in the first plane. If the axis is not free to rotate in the second plane, then the effect will be to rotate the axis in the first plane, precisely as if the flywheel were not spinning about the axis except for resistance due to friction.

These are the laws of the gyroscope, the common impression to the contrary notwithstanding. For example, if a fly-wheel is spinning about a horizontal axis and we attempt to raise one end of the axis, it will tend to rotate in a horizontal plane, the direction of the rotation depending upon which way the fly-wheel is spinning about its axis. If it is free to rotate in the horizontal plane, the apparent effect will be resistance to the force applied. If it is not free to rotate in a horizontal plane then we shall be able to raise the end of the axis exactly as if the fly-wheel were at rest, except for friction in the bearings. As the forces are large this friction may be considerable and it has undoubtedly led many experimentors who neglected this point to erroneous conclusions.

No Gyroscopic Effect with Common Position.—With the fly-wheel as commonly placed there can of course be no gyroscopic effect which would tend to turn the car over sidewise since the bearings will not transmit any force in this direction. The only possible effects are that if the front wheels be raised by an obstruction the car will tend to change its course to one side or the other, depending on the direction of the rotation of the fly-wheel. This effect is probably negligible. Conversely, when a car rounds a curve the gyroscopic action will tend to lift or depress the front wheels according as the curve is right or left handed. This effect is probably small but may help sometimes in making a car skid by lessening the pressure on the front wheels.

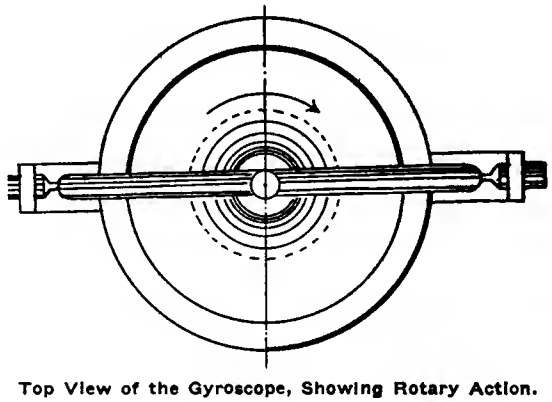
Turning now to the cars in which a fly-wheel placed horizontally and revolving about a vertical axis is supposed to prevent the car from over-turning sidewise, we find that the conditions are fundamentally different from those of the Schlick and Brennen applications of the gyroscope. In these applications both in the boat and the train the rotating wheel is so hung that its axis can turn in a fore and aft plane independently of the rest of the vehicle. It is upon this that their action depends, and in its absence there will be no gyroscope effect.

Herr Schlick in one of his papers expressly states that if the axis were fixed with respect to the hull of the vessel, the only effect would be to lengthen the period of rolling without decreasing the amplitude. This may be shown from theoretical considerations, but was proved experimentally on Schlick's boat. The axis is and must be fixed with respect to the frame of an automobile because of the necessity of transmitting the power to the wheels. The only effect therefore of the gyroscopic action would be to lengthen the period of rolling and not to prevent the car from upsetting.

Action of the Gyroscope of a Curve.—In turning a curve in one direction the pressure on the front wheels would be increased and in the other directions it would be diminished, depending on the direction of the rotation of the fly-wheel. The converse of this would also be true, that is, if we lift the front wheels the gyroscopic force produced will tend to turn the car over sideways; now it might very well happen that the front wheels would meet an obstruction while the car was rounding a curve and if the curve happened to be in the right direction the gyroscopic force would be added to the centrifugal force due to the curve and would actually increase the liability to upset the car on turning the curve.

Since these conditions would undoubtedly occur sometimes it may be said that the placing of a fly-wheel horizontally instead of decreasing the danger of upsetting sideways would increase the danger of such an accident eventually happening. The writer does not know whether the forces developed at ordinary speeds would be great enough to make any particular difference but the makers of the horizontal fly-wheel cars evidently believe that the forces are worth taking into account, so we may assume this in our discussion of the question.

It would of course be possible to mount the motor and its fly-wheel so that they could swing in a longitudinal plane as Schlick and Brennen do, and then of course the effect would be



Top View of the Gyroscope, Showing Rotary Action.

to prevent upsetting and we would even be able to run on two wheels. The writer believes that such a car has been built as an experiment, but none of the cars on the American market have, so far as he knows, adopted this plan and, as at present constructed, the horizontal fly-wheel increases instead of decreases the chance of the cars sometime upsetting when rounding a curve. Interested readers are referred also to the Jan. 16 and Feb. 20 issues, The Automobile for 1908.

Letters Interesting and Instructive

AUTO SIGNALING CODE.

Editor THE AUTOMOBILE:

[1,882.]—Having read the article in "The Automobile" of March 18 on the use of the horn or gong for a signal code (No. 1,795), I am pleased to say that the signal code which I will describe herein has been used by me for the past several years, and is the combination of lumbermen's and steamers' signals with no variations, and with the addition of using train signals.

(1) When running ahead and going to make port, or to stop,	One long and one short blast of horn, to be sounded not less than 30 yards from point of stopping.
(2) When coming to a standstill, or have made port,	One short blast.
(3) Going to start ahead, or leave port,	One short blast.
(4) When standing still and going to back up,	Two short blasts.
(5) Starting ahead slow on bad roads, slippery or muddy,	Three short blasts
(6) Going to turn to left at road crossing, to be sounded before starting to turn,	Four short blasts.
(7) Going to turn to right at road crossing,	Two short and one long blast.
(8) In passing a slower car on port side (left),	One long blast.
(9) In passing when abreast on port side,	One long and one short blast.
(10) When crossing intersecting roads, signal must be blown at least 20 yards distant from crossing.	Two long and two short blasts.
(11) Coming to forks of road, if any, cars, teams, vehicles coming in opposition use marine signal code; will turn to left; always keep on right side of roadway.	(Port) One long blast. (Starboard) Two long blasts.
(12) Calling for assistance, if stalled on the road,	Five long blasts.

In saluting other machines and occupants courtesy must be respectfully paid by proper use of horn. Any amount of noise will not do, as it would be confusing to other autoists. Several quick sharp blasts of horn will do. Blowing of horn unnecessarily is deemed inadvisable by the best autoists.

I have not seen any signals in a comprehensive form printed yet, and if these signals have been printed before in any magazine, I have not come across them.

Since 1903 I have been reading your magazine, "The Automobile," and several others, not being a regular subscriber, as I travel on the continent quite a bit, but now I will be at the Seattle A. Y. P. E. for the season of 1909, and I buy "The Automobile" at newsstands generally.

Hoping that the signals as used are easily understood by anyone.

COUNT JOHANN VON BUTALA.

Seattle, Wash.

We give the letter and code in full above, but would make the criticism that there are three pairs of signals, which are alike, and while it would appear that there is no danger of their conflicting with each other, it would be best to have different signals for the present duplicates. So we are suggesting changing three of the above as follows:

(3) From one short to five short.

(9) From one long and one short to one short and one long, a transposition.

(11) From one long to three long or possibly it would be better to leave this as it is and change

(8) From one long to three long.

TIMING OFFSET CRANKSHAFT.

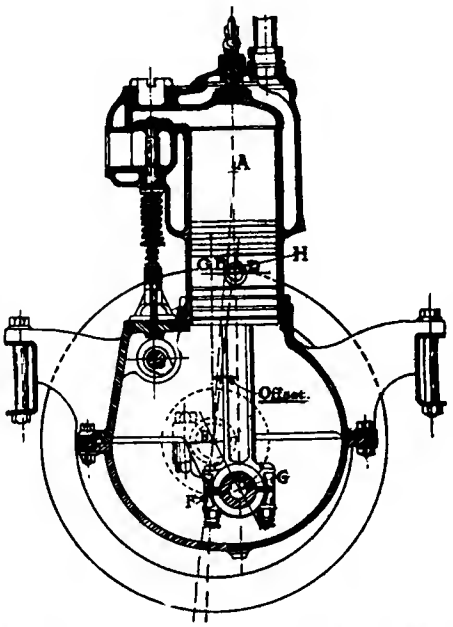
Editor THE AUTOMOBILE:

[1,883.]—Will you please tell me how to time an engine with an offset crankshaft?

A. E. MOORE.

Haverhill, Mass.

To time an engine having an offset crankshaft, the inclination of the axis of the connecting rod must be taken into account. As the figure shows, the connecting rod is vertical, and if the shaft center were not *de saxe*, the flywheel would be marked at the exact center of the upper face, namely at C. In the case where the center is set over, the rod, when in a vertical position as at G is not at the end of its stroke. If the flywheel were marked at C it would not indicate correctly the lower dead center. This does not appear until the three centers, piston pin, crank pin, and crankshaft are in line, as shown by the line D E F. The flywheel should be marked at this point, and the mark may be on a vertical line through the crankshaft center or on a diagonal as the line just indicated. In the latter instance, the mark for the lower center would be at H.



Section Through Engine with Offset Crank

Similarly, the upper dead center, if marked, would be at a vertical point above the shaft center as C, but would assume a different position, located on a diagonal, as at A, on the center line A B E.

Of course in actual timing, the upper and lower centers are not used, as good practice decrees an overlap for the valve action, but they have been used as an illustration in this case because their use simplifies the matter.

In the second figure, at the bottom of the page, the actual marking of a flywheel is shown for a complete cycle. In this the angles selected follow the best modern practice, being as follows: Inlet opens at 8 degrees past the upper center, and closes at 26 past the lower center, giving an inlet opening, total, of 198 degrees. Exhaust opens at 46 degrees before the lower center and closes at 5 past the upper. This gives the whole angle for the exhaust, 231 degrees on the crankshaft.

As shown, the markings are put on the flywheel directly above the center of the crankshaft, but the offset is taken into account.

CHEMICAL RECTIFIERS.

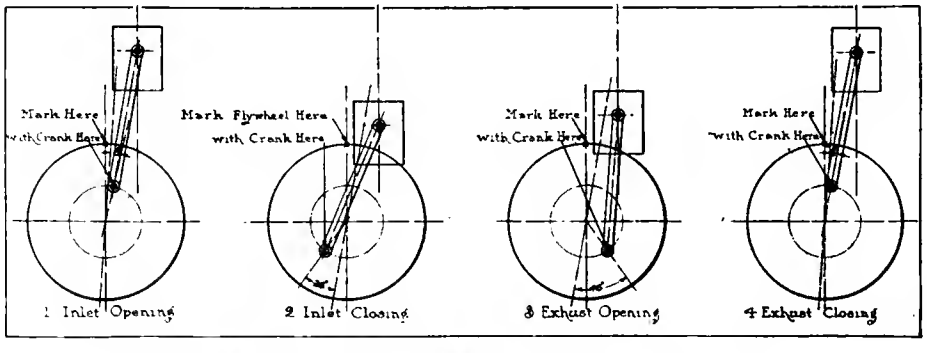
Editor THE AUTOMOBILE:

[1,884.]—Can you inform me of the name of the chemical or chemicals used in a corrector or rectifier for transforming alternating to direct current for charging of ignition batteries? The chemical I have reference to is of a crystal form, looking somewhat like borax. If you or any of your readers can tell me this, I would very much appreciate it.

B. M. JEWETT.

Claremont, N. H.

Of course we cannot be sure of the exact chemical which you have reference to, as



Diagrams Showing the Four Positions of the Offset Crankshaft.

a number of them are in use. Thus, if you use an aluminum-lead rectifier, the electrolyte may vary. This variation also affects the voltage of the current which may be higher with one electrolyte than with another. Dilute sulphuric acid will not allow the use of higher voltages than 20, while with potassium or sodium phosphate, as high as 200 can be handled. Ammonium phosphate raises the figure to one that allows of converting the ordinary electric light circuit of 220 volts. With a 110-volt circuit, a saturated solution of common baking soda can be utilized.

In practice, two of the aluminum-lead cells are placed in series, and there are two pairs of cells, one working with each half of the current. These are coupled in such a way that the whole current passes in the same direction through the accumulators to be charged. These cells have a very high internal resistance, and the lamp resistance ordinarily used must be passed through lamps intended for a current 20 volts below the ordinary to allow for the drop due to the internal resistance.

The mercury rectifier is more commonly used and a very complete description of one of these will be found on page 344, of THE AUTOMOBILE, issue of February 25.

HYDROMETER DESCRIPTION.

Editor THE AUTOMOBILE:

[1,885.]—In recent articles in "The Automobile" I have often seen the word hydrometer used; will you please describe this instrument and its functions? J. M. STEELE.

Tekonsha, Mich.

The hydrometer is an instrument for measuring the specific gravity of liquids, in other words, the density. It is an instrument resembling a thermometer with a large bulb on the bottom. The latter is filled with lead, mercury, or other very heavy substance, placed in there to make the instrument sink into the liquid even when thick and heavy. In the issue of April 8, THE AUTOMOBILE, several hydrometers are shown in position in liquids which are being tested. These will show you both the instrument itself and its use.

ON A VARIETY OF SUBJECTS.

Editor THE AUTOMOBILE:

[1,886.]—Will you please answer the following questions for me:

(1) What is the record for a bicycle, on a straightaway?

(2) Would not a three-cylinder two-cycle engine equal a six-cylinder four-cycle, as far as the smoothness of running is concerned?

(3) What is the difference between a low and a high-tension magneto? L. E. HOWE.

Liberty, Ind.

(1) You do not say what record you wish, that is, the question is too broad. To get an exact answer you would have to say definitely: the distance for which you wanted the record; the kind of rider, as amateur or professional; the kind of contest in which the record was made, as handicap or open race; whether in actual competition or against time; and if the latter, whether paced or unpaced; and if paced, whether ordinary or motor pace was used.

(2) Yes, a three-cylinder, two-cycle engine would run as smoothly as a six-cylinder, four-cycle. For equal size, it would not deliver as much power, and probably would consume more fuel.

(3) The difference between the two types of magneto is that they generate two entirely different kinds of current. Thus, the true high tension magneto will produce a high-tension current, the armature windings being such as to give this result. The low-tension machine, on the other hand is designed and wound so as to give a low-tension current. Under no consideration whatever can the high-tension machine be used for purposes where low-tension current is desired or necessary. The reverse of this does not hold, in fact, a number of ignition systems employ a low-tension magneto, the current from which is intensified by means of a coil, the resultant product being a high-tension current.

The difference in the use of the two forms of current lies in the fact that with high tension, the momentary intensity of the current is such as to jump a large air gap, as in the ordinary spark plug. With the low tension current, on the other hand, this does not hold and the current must be mechanically broken.

The devices for doing this are numerous and varied, too much so for a description here.

CYLINDER THICKNESSES.

Editor THE AUTOMOBILE:

[1,887.]—Will you please give me an empirical formula for figuring the thickness of cylinder walls for gasoline engines as used in automobiles? T. H. HEATH.

Buffalo, N. Y.

Thurston gives

$$T = aP_m d + b$$

in which T is the desired thickness, and a is a constant, for vertical cylinders the value of which is .0004, and for horizontal cylinders .0005. b is also a constant, with the value .2 for vertical and .5 for horizontal. P_m is the maximum pressure in pounds per square inch, and d is the diameter of the cylinder. Lucke gives $T = .075d$, and for cylinders above six inches in diameter $T = .075\,d + .3$. Rice compiled from current practice, $T = \frac{p\,D}{5300} - \frac{1}{8}$ inch for light automobile practice, which takes into account the average maximum internal explosion pressure.

FINE SCREW THREADS.

Editor THE AUTOMOBILE:

[1,888.]—I notice in the April 22 issue that fine screw threads have been standardized. Will you please publish the table of these as now standard? I have been waiting for this for many years and I believe that it would be of interest to many readers. C. V. ARMSTRONG.

Fulton, N. Y.

Although this table has been published before, we reproduce it herewith as taken from the "Automobile Trade Directory," pages 599, 600 and 602, for the benefit of Mr. Armstrong.

Table of A. L. A. M. Standardized Fine Screw Threads.

Latest Type of Packard "Thirty," Showing New Phaeton Body.

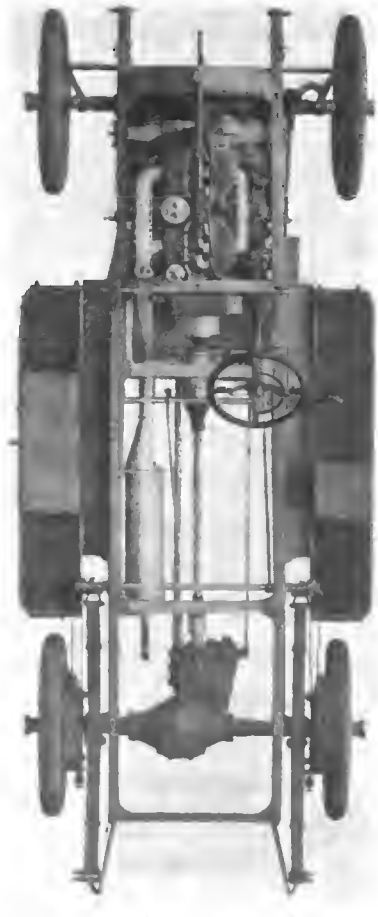
HAVING just completed the scheduled number of cars for the 1909 season nine days ahead of the time limit set, the Packard Motor Car Company of Detroit, Mich., is now announcing the details of the models upon which it will concentrate the energy of the enormous plant on the Boulevard for the coming year. This does not include any radical features, but is on the order of a continuance of its previous policy of confinement to a single quality product, in two sizes. These are the well-known "Thirty" and "Eighteen."

An examination of the appended details shows that the only very noticeable change is in the clutch, the type of which is a radical departure from previous Packard practice. Otherwise, the changes are all in the nature of small refinements, rendered advisable in the light of an additional year's experience.

The 1910 Packard "Thirty" may be obtained as the standard seven-passenger touring car, as a runabout, a limousine, a landaulet, with close-coupled body or with the new phaeton body. The latter body has been introduced as a practical vehicle meeting the demand for a fast, powerful car with low seats and small tonneau. The "Eighteen" is supplied as the standdard five-passenger open car, a runabout, a limousine, or a landaulet. Both cars are the same in design and construction, the essential differences being in size.

The chief features in which the 1910 Packard differs from the 1909, apply equally well to the "Eighteen" as the "Thirty." Those who are familiar with the car and the company's long-established policy, know that each successive model, instead of being a radical departure from the preceding one, is, instead, a careful development of it. **Consequently, the engineering work,** and **the improvements** each succeeding year, have reached a stage where the development comprehends even the most trivial feature of the car, tending toward mechanical refinement.

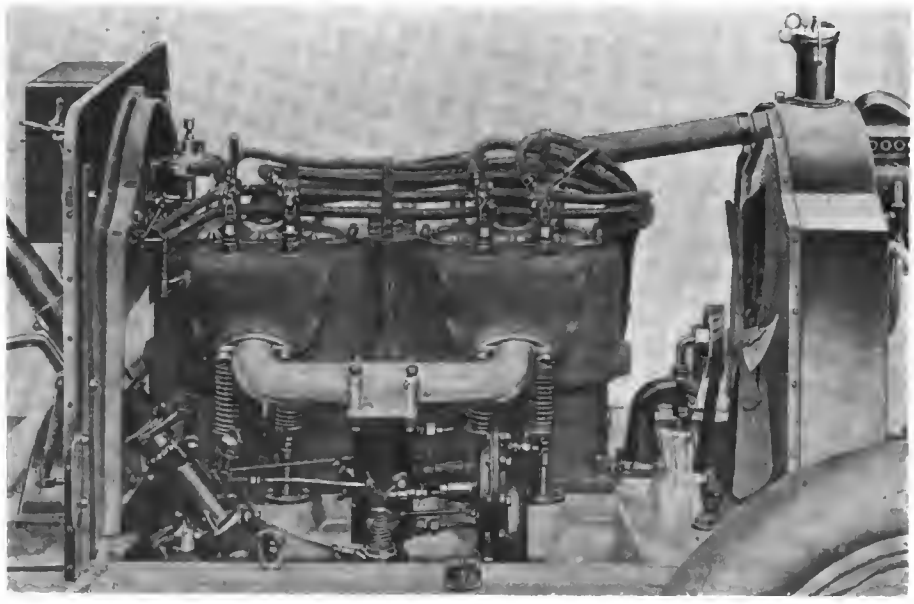
The motor is substantially the same as that of the 1909 car, improvements being confined to the mechanical detail. In order to obtain quiet running and efficiency under heavy duty, the main crankshaft bearings are of large diameter.



"Thirty" from Above Shows Simplicity.

Motor Shows No Changes.—The motor of the "Thirty" has four vertical, watercooled cylinders of 5-inch bore by 5 1-2-inch stroke, developing 30 brake horsepower at 650 revolutions. The "Eighteen" motor is of 4 1-16-inch bore by 5 1-8-inch stroke (103 x 130 mm), and develops 18 brake horsepower at 650. The cylinders are cast in pairs with integral water jackets and valve chambers. Cylinders and pistons are ground and interchangeable. The pistons are fitted with four ground rings. The three crankshaft main bearings are bushed with parsons white brass and are supported by massive webs. All bearing surfaces are ground. The connecting rods are drop forged. The crankpin bearings are bushed with parsons white brass and the piston pins with a special bronze. The valves are mechanically operated and interchangeable, the inlet and exhaust valves, on opposite sides of the cylinders. The camshafts are positively lubricated and protected, being encased within the crankcase. The camshaft, magneto, and water-pump gears are equally certain of lubrication and protection from dirt, being contained in a separate, but integrally-cast, oil-tight extension of the crankcase.

The crankcase is cast of a special aluminum alloy in three horizontal sections. The upper section, which forms the engine base, is supported directly on the side members of the main frame. All motor parts are completely protected by



Right Hand Side of Motor of Packard "Thirty," Showing Carbureter and Governor.

an integral web between the transverse supporting arms on each side, entirely enclosing the space between the motor and frame. The crankshaft bearings are held between the uppermost and middle sections of the crankcase. The bottom section is an easily removable oil well. The crankcase is divided into front and rear compartments by a central partition, which supports the middle crankshaft bearing.

No change has been made in the carburation system. The carbureter, which is of Packard design and manufacture, is of the float-feed, aspirating nozzle type with an automatic auxiliary air-inlet. The nozzle is in the lower portion of the cylindrical and vertical mixing chamber and above it is a butterfly throttle controlling the quantity but not the quality of the fuel mixture. The auxiliary air-inlet, which automatically governs the intake of air to keep mixture at correct proportion for all engine speeds, is a poppet valve under control of an adjustable coil spring. Spring tension to suit different atmospheric conditions is regulated by a small lever on the dashboard. Uniform temperature of the carburetor is maintained by the circulation of warm water through a jacket around the mixing chamber. A primary air-intake shut-off assists starting in cold weather.

Fuel Feed Is by Gravity.—The gasoline feed is by gravity, from a copper tank under the front seat. The total capacity, including reserve supply contained within the main tank, of the "Thirty" standard chassis, is 21 gallons. In the case of runabouts, the gasoline tank is on the rear of the frame and the feed is by a simple automatic pressure system. A convenient gasoline valve controls the main supply, reserve and shut-off.

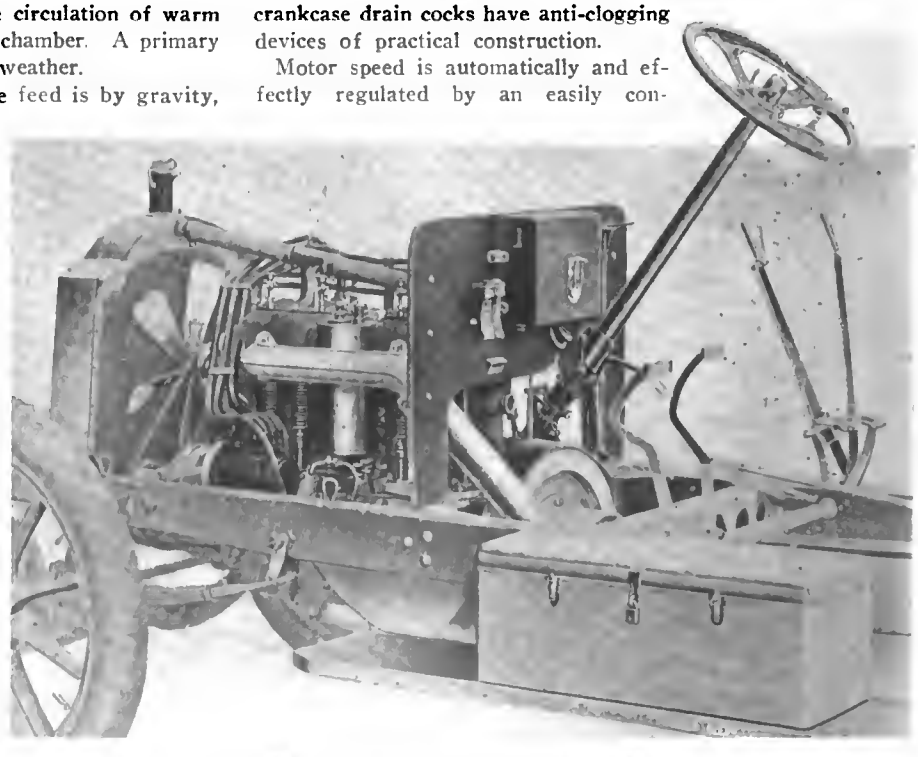
The water-cooling system is practically the same, with two small but valuable improvements. The suction strainer in the pump is quickly removable for cleaning, without the necessity of breaking any water connections. The filler cap has a new type of fastening which allows it to be quickly opened and closed and yet positively tightens it against leaking.

The water circulation is positive, by a gear-driven centrifugal pump. The radiator is of the cellular type. The capacity of the water-circulating system is five gallons. Forced draft, to increase cooling efficiency, is obtained by a belt-driven, ball-bearing fan, so mounted as to provide easy adjustment of belt tension. In the ignition system there are two detail improvements. The primary wiring, from the battery to the coil box, is carried within a neat protecting tube. The switch handle on the coil box is made in the form of a small lever, which is easily reached and turned by the driver, either with his hand or foot.

Features of the Ignition System.—The jump spark ignition is by the special Packard system. The current is supplied by an Eisemann low-tension magneto, mounted on the left side of the motor bed between the first and second cylinder pairs, and driven directly by enclosed gears. A storage battery, for starting the motor from the seat, is always in reserve, and is carried in an enclosed box on the right running board. The transformer coil for the magneto current and the vibrator coil for the battery current are arranged as a unit in a box on the dashboard. Between them is the combination hand and lock switch above mentioned. The commutator, to make and break the battery primary current, is on a vertical shaft at the rear of the motor, being driven from the exhaust valve camshaft by enclosed bevel gears. Combined with the magneto is a distributor which, like the high-tension wires and the spark plugs, is common to both magneto and battery systems. There are universally jointed knife switches at the spark plugs.

The splash lubrication system is the same simple, positive system formerly used. A double plunger oil pump feeds the front and rear compartments of the crank case, in which are independent oil levels. The oil pump strokes being adjustable, the oil feed is easily regulated. The pump is accessibly located at the left of the motor and is driven by a worm on the exhaust valve camshaft. Oil is taken from a vertical copper reservoir close to and between the pairs of cylinders, this location insuring uniform temperature and fluid, easily-flowing oil, even in the coldest weather. The capacity of the oil tank of the "Thirty" is one gallon. There are two drip sight feeds on the dashboard and the crankcase drain cocks have anti-clogging devices of practical construction.

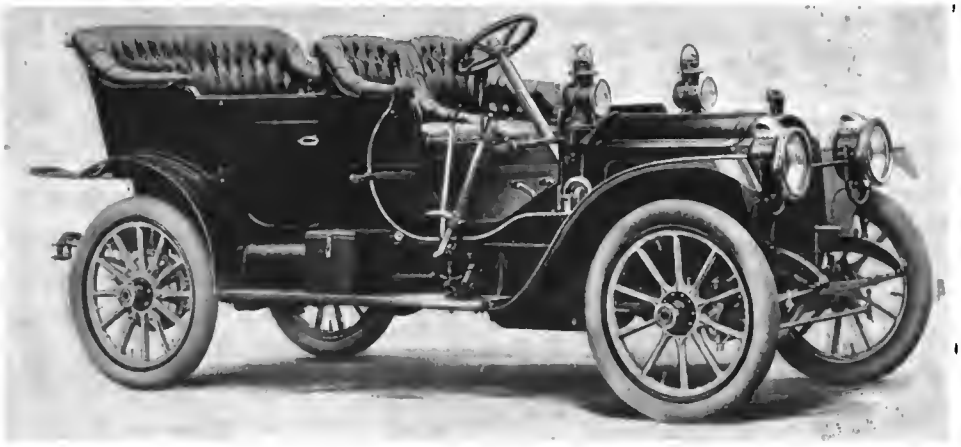
Motor speed is automatically and effectly regulated by an easily con-



Dashboard and Left Side of Regular "Thirty" Chassis, Showing Control Levers.

trolled hydraulic governor, incorporated in the water-circulating system and acting directly on the throttle. A pedal, cutting the governor out of action, provides for instantaneous acceleration and high-speed running. The throttle also is under control of a hand lever on the steering wheel. Another hand lever on the steering wheel advances and retards the spark.

The starting crank, which previously had been held by a leather strap, when not in use, is now held in an upright position by an automatic latch.



Packard "Eighteen" with Touring Body—Is Also Made with Runabout Body.

Clutch Shows the First Big Change.—One of the most noticeable mechanical improvements in the 1910 Packard is the new dry plate clutch. This clutch affords the desirable feature of gradual engagement, and, as it operates without lubrication of any kind, provides the same action in cold as in warm weather. By the use of a special lining material between the plates, the clutch will not burn, even under the severest usage.

An addition has been made to the gear-shifting hand-lever quadrant, which gives the lever a selective action in the same quadrant slot. This lever is at the rear of the single slot in the quadrant for first speed and at the forward end of the slot for third speed. The introduction of small shoulders on opposite sides of the slot allow the lever to be hurriedly and positively shifted in either direction into second-speed position. Reverse is obtained by the lateral movement of the same lever into a cross slot on the inner side of the quadrant and opposite the neutral position of the lever.

The toggle operating the reverse gear, which has been an exterior feature, is now protected against dirt and used by being enclosed within the transmission gear housing. The other general features of the transmission are the same as have previously been identified with the Packard.

Three forward speeds, providing the most efficient gear ratios for all kinds of driving, and the reverse are obtained by sliding gears, the third speed forward being direct drive. This gear set, as formerly, is combined with the bevel-gear final drive and the differential, to form a rigid rear axle unit, which is contained in an aluminum housing. The latter is internally ribbed to obtain maximum strength and rigidity. The differential gear unit is supported by its own bearings so that the live rear axle may be withdrawn without disturbing the gears. All gears in the transmission, final drive and differential, as well as the rear axle, run on imported annular ball bearings. The extremely long propeller shaft has effectively encased universal joints at each end.

All Brakes Located in the Rear Hubs.—There are four brakes, all acting on the rear wheel brake drums, thus obviating the application of braking power on the transmission. The external contracting brakes are operated by a pedal for regular use. The internal expanding brakes are operated by an emergency hand lever. A drum disc entirely encloses and protects each internal brake. The expanding brake segments are now secured by bayonet locks, preventing rattle.

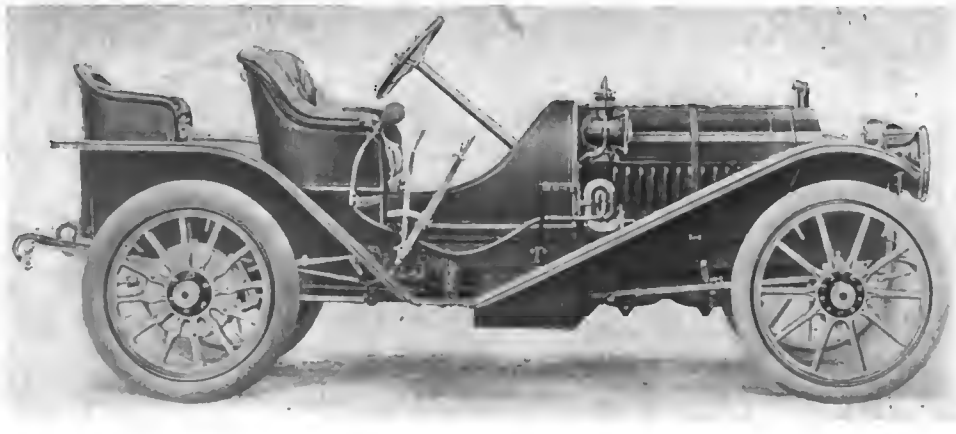
The improved steering wheel provides greater comfort for the hands, because the wood covering entirely encloses the metal rim and also extends onto the spokes. Another slight change in the steering gear is the addition of grease cups supplying lubrication directly to the steering sector shaft bearings.

The worm and sector are forged integrally with their respective shafts. The spindles and jawtype yokes are drop forged. The connecting rod, between the knuckles and the steering column, is placed above the front axle in a manner which minimizes stresses, vibrations, and consequent jar on the driver's hands. There are ball thrust bearings in the steering knuckles. The steering rod joints are encased and all connections have grease cups.

There are four wide semi-elliptical springs. In the "Thirty" the front springs are 40 inches long and the rears 56 inches long. In the "Eighteen," the front springs are 40 inches long and the rears 50 inches long. All spring shackle bearings are now lubricated by compression grease cups. The front axle is of steel tubing, of large diameter and heavy gage. The stationary sleeves of the rear axle are steel tubes, pressed into, and riveted within, the flanged collar of the differential housing.

Some of the Figures Are Interesting.—The wheelbase of the "Thirty" touring car is 123 1-2 inches and the tread standard, or 56 1-2 inches. The wheelbase of the "Thirty" runabout is 108 inches. The wheelbase of the "Eighteen" standard chassis is 112 inches, while that of the "Eighteen" runabout is 102 inches. The tires on the "Thirty" are 36 by 4 inches in front and 4 1-2 inches in the rear, except in the case of the runabout, on which they are 36 by 3 1-2 inches in front. On the "Eighteen," the tires are 34 by 4 inches, front and rear, except on the runabout, where they are 34 by 3 1-2 inches in front.

In all the standard bodies, the chief exterior differences are in the front mud guards and aprons, which have been carried farther forward to increase the protection against mud thrown backward alongside the bonnet. The price of the Packard "Thirty" touring car, runabout, phaeton or with close-coupled body, in standard finish and equipment, is $4,200. The price of the Packard "Eighteen" open car or runabout, in standard finish and equipment, is $3,200.



An Attractive "Looker" Is the Runabout Body on the "Thirty" Chassis.

Progress of the Aerial Brigade

Henry Farman's Own Aeroplane In Readiness to Make Its First Flight.

PARIS, May 14.—A sum of $20,000 voted by the French government for the encouragement of aeronautics is now being distributed to various promoting bodies. The manner of disposing of the entire sum has not been decided upon, but it has already been announced that the Aero Club of France shall have $8,600, the National Aerial League $7,000 for the formation of aerial pilots, and $1,000 to the Society of Aerial Navigation. Others that will receive grants are the towns of Pau and Douai, and the Aeronautique Club of France.

The Aero Club of France has decided that $2,800 of its government subvention shall be awarded as a cash prize for the longest aeroplane flight made this year away from a specially prepared aerodrome. One thousand dollars of the prize will go to the pilot of the machine, $800 to the builder, $600 to the constructor of the motor, and $400 to the builder of the propeller. Another prize of $1,800 will be awarded to the owner of the aeroplane which has remained in the air for the longest period between May 31 and December 31 of the present year. In the dirigible balloon class there is a prize of $1,600 for the longest round trip, or journey from town to town. Small airships, not exceeding 1,500 meters cubic capacity, will be awarded $400 for a journey of not less than 31 miles, starting and finishing at the same point.

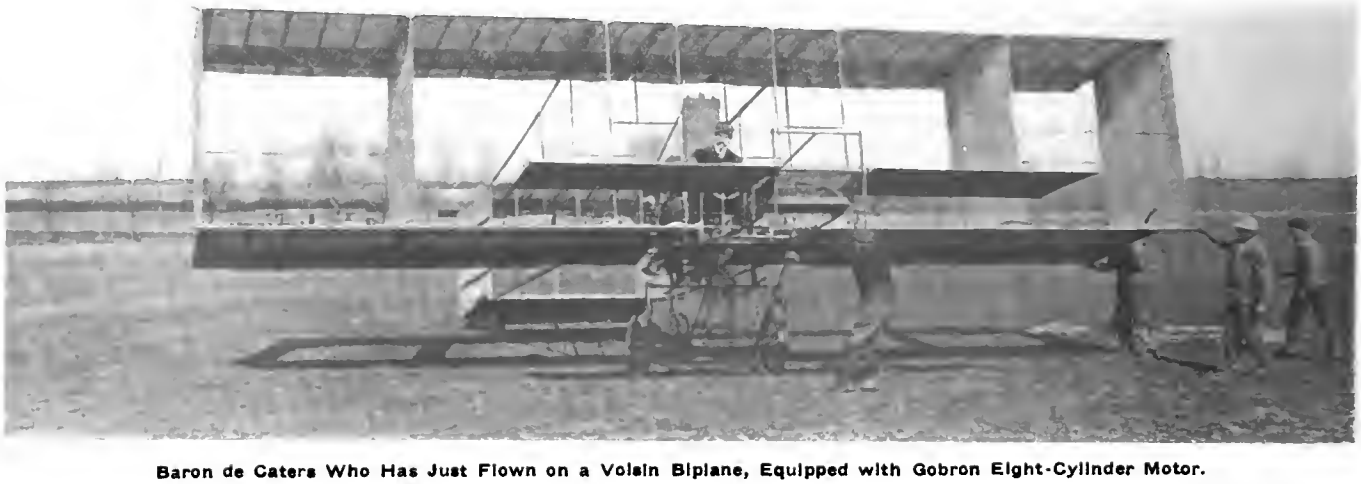
Clement Working to Win Deutsch de la Merthe Prize.

Adolphe Clement, head of the Bayard-Clement automobile factory, has resolved to win the Deutsch de la Meurthe prize with one of his new airships now under construction at the Astra factory. Engagement has already been made for the prize, to win which the balloon must fly 125 miles, starting from above the terrace of St. Germain, passing over the towns of Senlis, Meaux and Melun, to return to St. Germain. If successful, the owner of the balloon will be entitled to a gold cup valued at $2,000 and a cash prize of $4,000. The prize can be competed for on three successive years, each winner holding the cup for one year and being entitled to the cash prize of $4,000. The winner on the third year will retain the trophy. On the first occasion no time limit will be fixed during which the trip must be made, the only condition being that a regular speed shall be maintained. For the two following years the trip must be accomplished in a determined time.

Giant Garages for Airships "Liberte" and "Russie."

At Moisson, 30 miles to the northwest of Paris, the largest airship garage ever built is now being erected for the Lebaudy brothers. The huge building, which has a length of 430 feet, a height of 95 feet, and a width of 131 feet, will serve for the simultaneous construction of the two airships *Liberté* and *Russie*, the former for the French and the latter for the Russian government. Both airships are expected to be ready for their trial trips about the month of July. The huge sheds have a framework composed entirely of wood covered with red tiles. The end of the shed forming entrance will be closed by immense canvas screens mounted on rollers.

Germans Plan Airship Line—From Lucerne or Friedrichshafen to North Germany, via Frankfort-on-the-Main, will probably be the route of one of the first regular airship lines.



Baron de Caters Who Has Just Flown on a Voisin Biplane, Equipped with Gobron Eight-Cylinder Motor.

CANADIAN GLIDER BEING CONSTRUCTED.

OTTAWA, May 17.—Although this part of the Dominion has been rather backward in aerial experiment, a prominent resident of this city, Dr. Mark G. McElminney, is making great progress with his gliding machine, and hopes soon to be sailing through the air, from hill to hill. The machine, which is nearing completion, measures but 20 feet over all, will have 160 square feet of surface, and weighs but 50 pounds. With it Dr. McElminney expects to learn much about the gentle art of flying, the Gatineau hills being the scene of his experiments. Others are watching his work very closely, and if the machine is a success not only will he build a larger one, but numerous others will also build. It is barely possible, says the doctor, that the present machine may form the framework for an airship, power being added to it later.

KRUPPS FIGURE IN A WRIGHT COMPANY.

BERLIN, May 17.—In the formation of the Wright Flying Machine Company, in this city, it has developed that three of the largest corporations in Germany are interested in the new one. They are the Krupp Works, of Essen, the Allgemeine Electrizitäts Gesellschaft (General Electric Company) and the Ludwig Loewe Company, the last being a leading manufacturer of machinery and machine tools. It is thought that this presages the broadening of the aeroplane branch of aeronautics, and the building of machines upon a large scale. The new concern is called the Flug Maschine Wright Gesellschaft.

Putting Up the Framework for the "Russie's" Garage.

FIRST FRENCH WRIGHT MACHINE USED.

CANNES, FRANCE, May 17.—Comte de Lambert yesterday ascended in the first of the Wright aeroplanes to be built in this country. Four successful flights were accomplished at the Aerial aerodrome, each of a mile and a quarter, in which several difficult turns were taken.

CODY BREAKS ENGLISH RECORD IN FLIGHT.

LONDON, May 17.—S. F. Cody last Thursday broke the English record by flying a mile at a height of 30 feet with an army aeroplane at Aldershot. The Prince and Princess of Wales heard of this and asked Cody to repeat his flight, but in the attempt he smashed into an embankment after going 250 yards. The aviator escaped without personal injury, but his aeroplane was considerably damaged by the collision.

British Tri-plane That Is Being Tested on Lea Marshes, by A. V. Row—It Is Driven by Six-H.P. Jap Motor.

General View of Starting and Finishing Point—Italian Aristocracy to Be Seen in Foreground.

CIUPPA, AMATEUR, DRIVING SPA, WINS THE FLORIO

PALERMO, SICILY, May 5.—The Targa Florio, the Sicilian mountain race that has seen the exploits of Lancia, Nazzaro and other captains of the steering wheel and which has as its previous winners Cagno, Nazzaro and Trucco, was this year a race of eleven amateurs mounting machines of widely different powers. Ciuppa, a young Italian sportsman, who has not previously been heard of in connection with big races, came home first, having covered the single round of 93 1-5 miles, including the changing of two tires in 2:43:19, which means that his Spa car, one of the most powerful in the group, had maintained an average speed of 34 2-5 miles an hour.

As the drivers were exclusively amateurs, Vincenzo Florio, the millionaire sportsman who is responsible for financing and donating more automobile races than any man living, felt justified in running for the gold cup and $1,200 in cash. He mounted a Fiat four-cylinder of 4 4-5 bore—the car which had Lancia as its driver in the Targa Florio of 1907—on which he went away first and finished first to the wild enthusiasm of his compatriots. But there was the dashing Ciuppa, started 19 minutes later, who had to be reckoned with, and when he arrived and the time allowance had been made another cheer had to be raised, for the Chevalier had gone down to second position exactly one minute behind the unknown amateur.

Third place went to Airoldi, driving a fine little Lancia four-cylinder car of but 3½ inches bore, which finished twelve minutes behind the winner, beating a Spa with cylinders of the same size, but six in number, by a margin of 25 minutes. Deseta's big Itala, with a four-cylinder engine of exactly the same size as that driven by the winner, could not get better than fifth place, one minute behind the fourth car. A little four-cylinder De Dion, with a piston diameter of slightly less than three inches, came in sixth, but was outshone by its two-cylinder stablemate having a moderate 10-horsepower rating. Berliet had trouble with tires from beginning to end, with the result that he was a tailender with a small De Dion voiturette entered more with a view to showing reliability than with a hope of capturing the gold cup.

Last year Trucco, on an Isotta-Fraschini, made the record, with an average speed of 35½ miles an hour, the race then being run for 379 miles compared with but 93 miles this year. The tabulated result of the race is as follows:

	Car.	Driver.	Time.
1.	Spa, 4 cyl., 5.1 inches bore	Ciuppa	2.43.19
2.	Fiat, 4 cyl., 4 4-5 inches bore	Florio	2.44.19
3.	Lancia, 4 cyl., 3 1-2 inches bore	Airoldi	2.55.25
4.	Spa, 6 cyl., 3 1-2 inches bore	Cortese	3.20.40
5.	Itala, 4 cyl., 5.1 inches bore	Deseta	3.21.56
6.	De Dion, 4 cyl., 2 9-10 inches bore	Stabile	3.21.32
7.	De Dion, 2 cyl., 3 1-10 inches bore	Olsen	3.34.55
8.	Berliet, 4 cyl., 4 7-10 inches bore	Rebolia	3.37.57
9.	De Dion, 2 cyl., 3 1-10 inches bore	Tracona	3.58.46

PEUGEOT WANTED THE CUP.

PALERMO, SICILY, May 5.—Messina in ruins appeared to be a sufficient reason for abandoning the usual Spring automobile races round the mountainous Sicilian course, and instead of an entry blank an invitation was forwarded to the Lion Peugeot firm to return the trophy which they won with one of their single-cylinder cars last year. But the firm preferred to keep the trophy and sent an engagement of three cars, thus forcing the race to be held. De Dion being the only other firm invited to take part in the contest, but six cars started.

When the first of the two rounds was finished Guippone was leading with his teammates, Goux and Boillot, not far behind. The three De Dion cars were still in the run and going well, but were somewhat lacking in speed. Just when it seemed that Giuppone would bring his Lion Peugeot home first and beat last year's time, he came to a stop with his gasoline tank empty. The finishing post was three and a half miles away, and was the nearest place at which more fuel could be obtained. Jumping

out of his car and seizing the bicycle of a spectator, the Italian driver of the French machine sped down the precipice-bordered road and in a very short time was back again with a gallon can of gasoline on his handlebars.

The mishap cost him first place, for while he was held up his team mate, Goux, went by and definitely captured the trophy for Lion Peugeot, his time for the 186 miles of mountain scaling being 6:48:2. Giuppone got home second, a little less than four minutes behind the leader. The third Lion Peugeot fell a victim to one of the hundreds of bad turns, leaving third place for Olsen on a De Dion Bouton in 7:47:55.

HEAVY TAXES ON BRITISH MOTORISTS.

LONDON, May 6.—While the imposition of fresh taxes on automobiles has for long been regarded as inevitable, few motorists were prepared for the drastic measure introduced by Lloyd George, Chancellor of the Exchequer, in his budget yesterday. At present, apart from the registration fee of £1, an annual tax of £2 2s. is the sole charge on cars, whatever be the power. The new taxes vary according to the horsepower, and for this purpose the R. A. C. rating of D^2N over 2.5 will be used—for the present, at any rate. The scale is as follows:

Under	6.5	HP	£2	2	0	Under	33	HP	£	8	8	0
"	12	"	£3	3	0	"	40	"	£10	10	0	
"	16	"	£4	4	0	"	60	"	£21	0	0	
"	26	"	£6	6	0	Over	60	"	£42	0	0	

Motorcycles are £1 each, regardless of power.

These taxes come into force at once and are payable annually. A concession is made in the case of doctor's cars, for which only half the above amounts will be charged. Public service vehicles, including motor busses and taxicabs, are exempt from these taxes and will only be rated under the old system.

This is not all, for a tax of 3 pence per gallon has been imposed on petrol, subject to a rebate of 50 per cent. in the case of public service vehicles. These taxes are expected to raise a minimum of £600,000 per annum and the whole of this money is to be expended on the "improvement" (as opposed to "upkeep") of main roads. It is too early yet to record the opinions of the industry's leading men, but the feeling seems to be that the new taxation will mean a general reduction in horsepower for next season's cars, and may lead to extensive development of the long stroke and the two-stroke cycle engine. The tax will also press heavily on the public service companies.

LUMINOUS FRENCH REGISTRATION NUMBERS.

PARIS, May 14.—The decision of French authorities that all cars shall carry their rear registration number in the form of transparent letters and figures lighted by a lamp at the rear, or by an ordinary lantern placed in such a position that the plate can be read as easily by night as by day, has caused considerable disturbance among owners and as much activity among inventors. A box with a luminous front and containing an oil or kerosene lamp is at best such a delicate and dirty contrivance that there is every encouragement to replace it by electricity if this can be done economically.

An interesting device on these lines, consisting of a metal case the necessary length and height to conform with the police regulations, and a plate front with transparent figures, has been produced by Engineer Lacoste. The depth of the box is only 1½ inches, which thus gives a luminous number plate of smaller dimensions than anything else on the market and as easy to fix as the simple plate of regulation size. The plate carrying the figures is secured in position by entering two grooves, and maintained by an end plate fastened by two screws. Within the box is a very small electric lamp, receiving its current from a storage battery carried on any convenient part of the car. The feature of the appliance is a number of mirrors within the box by the use of which the whole of the figures and letters are perfectly illuminated with a minimum consumption of current. Two screws are sufficient to attach the box to the rear of the car, a cable connecting the lamp with the storage battery and a switch are all that are needed to secure a rear number that will never go out, and that will never become smoked so that it cannot be read "as clearly by night as by day," in accordance with the police regulations.

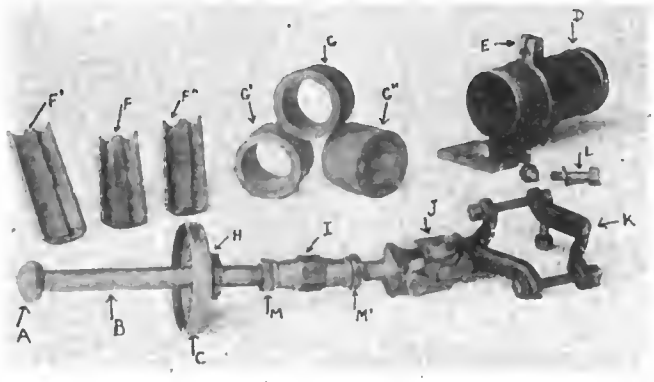
GERMAN COMMERCIAL TESTS IN PROGRESS.

The German military and commercial car tests are now well under way, forty vehicles in all having started from Berlin. Those participating in the latter event wind up their tour in Stuttgart on May 13, while the competitors in the military trial have to get back to the metropolis by May 21. A motor train, fitted up as a workshop, accompanies this section, which, having to be much longer on the road, have shorter daily tasks put them than the industrial section, although the stages are the same.

Arrival of Airoldi and the Little Lancia, Which Finished a Comfortable Third.

LATEST IDEAS IN ABOLISHING VIBRATION

PARIS, May 14.—Shock absorbers are one of the minor improvements that still interest both inventors and automobilists alike, and will doubtless continue to do so until bad roads cease to exists. One of the latest ideas in this direction, produced by Leon & Ballet, two French engineers, consists of a cylindrical metal case attached in a vertical position



Leon & Ballet Shock Absorber Entirely Dismounted.

to the side member of the car, and containing a piston the prolongation of which is secured in a suitable manner to the car axle. Within the cylinder, D in the illustration, are three superimposed rubber rings G G' G'' forming a lining for the hardened steel plates F F' F'', forming three grooves when assembled together. It is within these grooves that the round headed end of the connecting rod A is lodged. When not subject to a shock, the ball head occupies a central position, with a play of about one-eighth of an inch all round.

On the car, springs being depressed, the ball head is, of course, driven upward, and as the grooves become shallower as they near their upper and lower end, the three plates are expanded against the rubber wall, thus progressively braking the movement. After passing the central position on the recoil, the same braking effect takes place in the lower portion of the slides. It will be noticed that there is a universal joint in the connection between the ball head and the axle and that the connecting rod can be regulated in length to suit the requirements of the car or to take up wear.

Another inventor, Georges Levi, would abolish vibration and road shocks by the use of a double set of springs, the second set being carried above the first set and united to them at the extremities by a suitable coil spring connection. The system can be applied to any type of suspension, but where the platform type is used it would be fitted to the transverse spring. In the case of a three-quarter elliptic it would be the quarter-length that would be supplemented.

It is claimed for the system that under a light load only the upper set of springs would be called into action, thus removing the disadvantages of hard springs so disagreeable on many cars when running light. Under a heavy load the two springs practically become one and work as one unit. On striking a rut in the road the two springs receive the shock together, but it is the lower one that ceases operation first, the load being left on the upper one alone, which has not sufficient power in itself to oscillate the body. The apparatus has the quality of simplicity and from tests that have been made appears to remove a large amount of vibrating and pounding on rough roads.

Showing Same with Piston and Rubber Rings Outside Case.

NEW AMBULANCES OF THE PARIS MUNICIPALITY.

PARIS, May 14.—The Paris municipality has adopted an improved type of ambulance which, though possessing little that is luxurious, is well equipped with practical appliances for the benefit of its occupants. The chassis has nothing that is distinguishing, being a standard Panhard 16-22, with chain drive. The body, built by Lamplugh, provides a rear entrance to an entirely metal-lined interior. The hospital bed is run onto a cradle down one side of the vehicle, attached by means of coil springs to the walls, and a suitable arm. A plentiful supply of

Levi Compensating Spring.

Same on Platform Type.

both hot and cold water is provided, the tanks being on the outside of the vehicle to the left of the driver. Within the ambulance is a washbasin similar to those used on trains and a single two-way tap providing either hot or cold water at will. Artificial lighting is by means of a special dynamo carried on the footboard and run off the transmission shaft; this supplies current for the head and side lights, as well as for the interior. A series of these ambulances are about to be put into service in Paris, replacing the present horse-drawn vehicles.

NEW AUTO ROAD TO SURMOUNT THE ALPS.

PARIS, May 14.—The Touring Club of France is responsible for a subvention of $37,600 toward the construction of what will be the highest road in Europe open to automobile traffic. The new Alpine highway in which the club is interested will unite Thonon and Nice, following as closely as possible the Italian frontier, and passing through some of the most picturesque parts of the Alps. The highest elevation is on the Col de l'Iseran, over 8,000 feet above the level of the sea.

After Leaving Sedalia, Colorado, the Approach to the Snow Clad Rugged Rockies Is Imposing in Sublimity.

SURVEY OF GLIDDEN TOUR ROUTE PRACTICALLY COMPLETE

ROUTE-MAPPING for the course of the Glidden Tour is practically completed, for this week has been used by Dai H. Lewis, the official pathfinder in the E-M-F touring car, in covering the roads between Denver and Kansas City. As the run from Omaha to Denver was one long hill climb, the four days to be spent between the western turning point and the finish will be just as long a coast, a feature of the last leg of the contest. The pioneer party reached the "Mile-High City" last week, Wednesday, rested there until Friday, and then began the "trek" across southeastern Colorado and Kansas, expecting to consume a week in the distance to be dealt out to the contestants in four sections. Night stops will be made at Hugo, Colorado, and at Oakley and Salina, Kansas, with Pullman accommodations at these points, as will be the rule through part of Iowa and Nebraska on the westward journey.

The drop in altitude from Denver to Kansas City is 4,489 feet, or about seven-eighths of a mile. The road mileage by the chosen route cannot be stated, of course, until after the pathfinding is completed, but the route follows closely the line of the Union Pacific railroad, and the distance by rail is 640 miles. The second day out from Denver, going from Hugo to Oakley, there is a grand coast of 2,046 feet, or nearly half a mile downward in about 160 miles. This gives an average grade of thirteen per cent. and good braking will be at a preminum. The next day, from Oakley to Salina, there is a drop of 1,818 feet, but the distance is nearly 200 miles, so the average of grade is a little less than 10 per cent. Those two are the big coasts, the final day offering only a drop of 482 feet in 190 miles. These will be royal days, as well for keen competitive sport and for scenery. At night the contestants will camp in sleeping cars standing on lonely sidings near small towns. It is probable that, except for the big fête days at Minneapolis and Denver, these last few stages of the tour will be the most memorable of all.

Thus as mapped out at present the runs of the several days are as follows: First, Detroit to Kalamazoo, 142.2 miles; second, to Chicago, 173.2 miles; third, to Madison, Wis., 175 miles; fourth, to La Crosse, 154.4 miles; fifth, to Minneapolis, 178 miles; sixth and seventh, in Minneapolis; eighth, to Mankato, Minn., 132 miles; ninth, to Fort Dodge, Ia., 143 miles; tenth, to Omaha, Neb., 186 miles; eleventh, to Kearney, Neb., 200 miles; twelfth, to Julesburg, Col., 206 miles; thirteenth, to Denver, 208 miles, and then after a Sunday in that city, the four days across the plains to Kansas City, finishing July 29.

Inasmuch as there were enough evidences of the number of cars to enter by May 15, to insure the Pullman company of sufficient patronage to operate the minimum number of sleeping and dining cars, the entry list at $200 per auto will be held open until June 15. Thereafter an additional hundred will be added to the entry fee. The Pierce-Arrow Motor Car Company has announced its entry of four six-cylinder cars, two of 48 horsepower each for the Glidden contest proper, for touring cars, and two runabouts of 36 horsepower each for the Hower Trophy.

An interesting feature of the pathfinding trip is the rapidity with which the news of the progress of the car has been communicated to the inhabitants of the country through which it has passed. Everybody seems to be waiting for it.

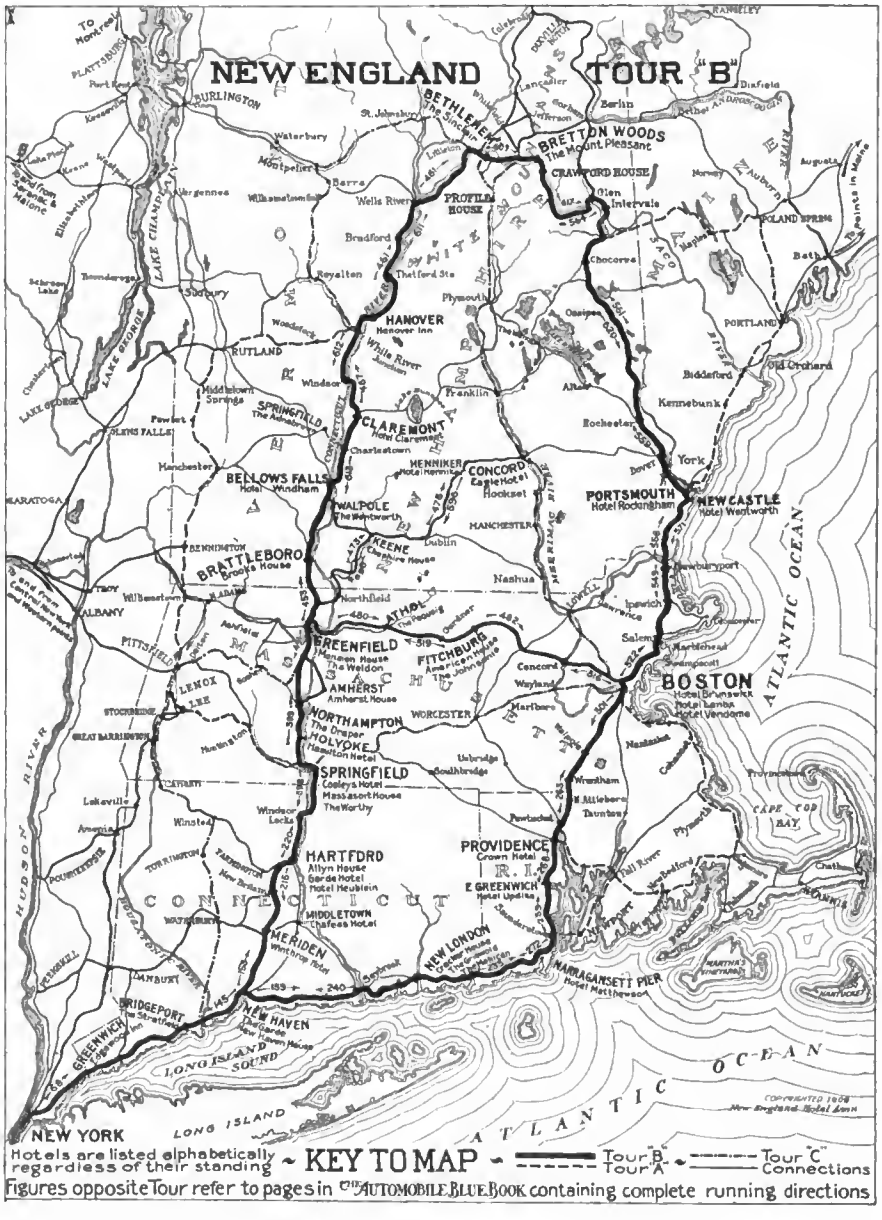
TOURING 'MID NEW ENGLAND'S VARIED SCENERY

NEW ENGLAND is replete with magnificent scenes and routes for the automobile tourist, and a trip through a valley conceded to be one of the most picturesque of all the beautiful valleys along the Atlantic seaboard, that of the Connecticut River, is the second of a series outlined by the New England Hotel Association. From New York City to the White Mountains and return is a tour of great popularity with automobilists from all over the country, because in these runs of between 700 and 1,000 miles there are views which are distinctive in their natural beauty, and roads which are the best that can be built. These pertinent features, combined with hotels of marked superiority, give those who tour conditions which equal the far-famed ones of the old world. Compiled in connection with the "Official Automobile Blue Book," the routes suggested by the hotel men are such as to offer either leisurely runs, with stops for luncheon at inns of recognized merit, of fairly quick circuits, or of a hasty trip with long daily mileage when necessary. It is hardly possible to go more than a few miles without passing the headquarters of members of the association.



Three tours have been chosen as those best suited to the owner of an automobile who woudl tour in the eastern-most tier of the United States, designated as "A," "B" and "C." The first was described in The Automobile of May 6, showing a tour of nearly 1,000 miles through the Berkshire Hills, the Green Mountains, the White Mountains, an extensive run along the seacoast of Maine, New Hampshire and Massachusetts, and the shores of Long Island Sound. Tour "B" which is presented here is different in its nature, with delightful characteristics of its own, an itinerary that can be used either as a supplement to any of the others or as a route in preference to them. The route out of busy New York is a common one to the series as far as Bridgeport, where "A" goes north, or as an option as far as Springfield, where "A" turns northwestward and "B" continues northward. The shores of Long Island Sound are followed on the famous old Boston Post road to New Haven through some of the most beautiful suburbs of the metropolis, between shady lawns surrounding imposing residences, with the views of the water meeting the eye every few hundred yards.

At New Haven a turn is made, the Yale campus passed and a short run taken to the State Capitol, Hartford, first going through Meriden and New Britain, both busy manufacturing places, so that when the Connecticut River is seen at Hartford, and later crossed, its beauty is realized. For about 225 miles of the total 790 the auto will be driven along the banks of the river, through four of the six States. The roads are generally excellent and at no place less than good, or perhaps fair, while the fertility of the country, the verdure-lined banks of the stream, and the general thriving appearance is sufficient to relieve the most overworked mind, and thus is a source of a real vacation and a thorough pleasure. In addition to the main route, however, there are numberless points from which pleasant detours may be made, all of which are given in detail in the "Blue Book." Massachusetts is entered below Springfield and crossed directly to the north, through Holyoke, Northampton and Greenfield, at the last place meeting the route from Boston through Fitchburg and Athol. From the southern border of Vermont to the White Mountains at Bethlehem or Bretton Woods the tourist is led back and forth into New Hampshire, through fine pastoral scenery, into mountain passes that compare with anything the world possesses.

A wealth of wild and fascinating country is offered around the mountains, and then one of three routes may be chosen for the trip to the "Hub," the one under consideration being a middle one, direct to the ocean at Portsmouth. From Portsmouth to Boston is over roads that are famous for their hard surface, the delight of the autoist. Providence and Narragansett Pier are prominent points touched in Rhode Island, then New London in Connecticut; at New Haven the outward bound route is met, and the run into New York city a familiar one. Of course, the trip can be made in the opposite direction if desired.

INFLUENCE OF LARGER WHEELS.

The fact of the influence of large wheel diameters, so thoroughly discussed a few years ago by manufacturers and resulting in the adoption of 36-inch wheels by nearly every maker of large cars, is coming to the front again as the result of recent meritorious performances of the wheels with increased measurements. Carriage manufacturers have long recognized the material advantages accruing to the use of the larger sizes, but it was not until recent years that the automobile manufacturers generally took up with the idea.

Beginning with the agitation of two years ago, sizes were increased all along the line, but a few braver ones did not stop with the generally accepted 36-inch size. Now it appears that the latter were in the right, and sizes again may be subjected to an upward revision which will make a new standard for large cars.

There are now on the American market two cars which may be had with large, or, as they have been called, "carriage-sized" tires. One of these, the one expressing the preference for the larger size of the two, recently came through a very severe endurance contest with a nearly perfect score, while the large tires were the only ones in the whole "bunch" of contestants which went through without any trouble.

In many cases of trouble with deep mud and other severe road conditions, the bigger wheels were always "on the job," and, as in mud, their very size was an advantage to the car so equipped.

Thus also in the recent one-gallon economy contest in New York City the larger sizes were always to the fore. Of the first four but one was small, and that not very small. The average of these four was 34 inches, which is commonly regarded as a large size. Down at the end of the table are found all of the small sizes and but one of the large ones. This would almost allow of the deduction that large tires, meaning large diameter wheels, are a form of added economy. In this connection it is to be regretted that two exactly similar cars with different sized wheels were not in the contest so that this point could be settled. It is believed that 38- or 40-inch wheels, and a gear ratio which took this into account, would have allowed the winner to improve even the excellent and very noteworthy score made.

One factor which formerly contributed to the use of small diameter wheels, or rather which made them a necessity, is no longer in force. This is the matter of tire sizes. At first, pneumatic tires were made only in small sizes, which meant small wheels or solid tires. Now, this no longer holds, as tires may be had in any desired size, and tire manufacturers would gladly make other larger sizes if the demand warranted. So, one by one, keeping pace with the increase in demands, the obstructions and possible factors which have held back the use of larger wheels have been removed, or reduced to a negligible quantity.

All of the arguments applied to the use of any size larger than 28 inches apply with equal force to the still larger sizes above 36 inches. Summing up all of the points, the time appears ripe for another increase in the size of automobile wheels.

* * *

WHERE PREPARATION MEANS MUCH.

While it is probably true that there are a great many people capable of starting out on a long-distance automobile tour without bothering much in the way of preparation, trusting to the mood of the moment for the picking of a night stop and following unexplored roads, the wisest plan in this country of doubtful hotel accommodations is to plan the route carefully and pick a hostelry of known reputation for the sleep which always comes after a day on the open road. Nothing spoils so much the pleasure of automobile traveling as poor accommodations for the night and the invariable accompaniment of mediocre replenishment for the hungry inner man. Don't endeavor to do too much in a day, and it is much the better to make an early start and get well along on the day's run before the laggards of the highway have appeared for their midday siestas or else their eleventh-hour scorching to reach the next big town.

A mingling of town and country in the matter of picking the journey's interruptions adds variety to the trip, which is especially sadly missing when only the crowded city entices the traveler greater than the lure of the green-dressed country with its valleys, and lakes, and rippling streams. Hence, study well before you start out for a long trip, leaving the hit-or-miss episodes for near-home chances, for it is a case of where time spent in preparation will be hours gained on the road, to say nothing of the consequent comfort from utilizing the carefully compiled information of the Blue Book series.

PENNSYLVANIA LAW EFFECTIVE JAN. 1.

HARRISBURG, PA., May 17.—Automobilists from outside of Pennsylvania should make note of the fact that the new Pennsylvania law does not go into effect until January 1, 1910. The first impression was that the clause in regard to reciprocity to non-residents of those States granting reciprocity to Pennsylvania autoists would become effective at once. According to Joseph W. Hunter, State Highway Commissioner, this clause of the law awaits the application of the entire act, which does not become effective until January 1, 1910. Hence, it is stated regretfully, that Pennsylvania will continue the present year to ask non-residents to obtain licenses as before from the State Highway Commissioner, the fees remaining at $3 for driver's license, yearly renewal January 1; registration of car unnecessary, but driver's license tags must be carried.

IN ENFORCING NEW JERSEY'S LAW.

TRENTON, N. J., May 17.—In filing complaints and evidences against non-resident automobilists with the State Motor Vehicle department, magistrates must hereafter accompany same with a 30-cent fee and the necessary mileage. This decision was handed down last week by Assistant Attorney-General Gaskill in settling a dispute between Magistrate Noar, of this city, and Motor Vehicle Commissioner Smith. The former contended that the latter was compelled to push all cases sent to him by magistrates; the commissioner said that in many cases the costs of prosecution would be prohibitive. Attorney-General Gaskill's opinion states that the Motor Vehicle Commissioner may issue summonses in cases "which he regards as meritorious." It seems certain that future prosecutions will be confined to those cases where there is a good chance of getting at the culprit.

NEW PHASES OF OHIO AUTO LAW.

COLUMBUS, O., May 17.—Several important rulings relative to the operation of automobiles have been made by the Ohio automobile department and the attorney-general. The department has decided that when a member of the family owning a car drives it is not necessary to take out a chauffeur's license. Identification by the tags is considered easy when the car is driven by the owner or a member of the family. In contrast to this is the statement from the attorney-general that when a car is owned by a corporation and used by many of the officers and stockholders, each one will have to provide himself with a license as chauffeur, because the ownership of the machine by the corporation does not identify officers and stockholders.

WISCONSIN SENATE PASSES AUTO LAW.

MILWAUKEE, WIS., May 17.—Recklessness determined by the occasion may be the speed limit of automobiles in this State, with a nominal limit of 25 miles per hour, if the bill which has passed the Senate goes through the Assembly and is signed by Governor J. O. Davidson. The bill was prepared by Senator E. E. Page of this city and practically wipes out the speed limit, substituting the terms of recklessness, and amendments were made in the upper body requiring operators to slow down at corners and prohibiting persons under 16 years of age from running a car unless accompanied by parent or guardian.

PENNSY'S CROSS-STATE ROAD MUST WAIT.

PHILADELPHIA, May 17.—After long and serious consideration, Governor Stuart, on Friday last, reluctantly and sorrowfully vetoed the cross-State highway bill. This measure, which the Governor bent every effort to put through both houses of the Legislature, called for the expenditure of $5,000,000 within three years, and with so many demands upon the treasury from schools, hospitals, the indigent insane and the consumptive poor, His Excellency could not find it in his heart to sign the bill.

MRS. LONGWORTH GETS OHIO TAGS.

COLUMBUS, O., May 17.—Fred H. Caley, superintendent of the Ohio State automobile department, has shipped to Mrs. Alice Roosevelt Longworth a set of tags for a gasoline machine with which she expects to do considerable touring in Ohio this Summer. The tags were shipped to Washington, D. C.

FUTURE OF GRAND PRIZE WORRIES SAVANNAH.

SAVANNAH, GA., May 17.—The Solid South is interested in the action of the Savannah Automobile Club relative to the future of the Grand Prize Race. The club held a meeting recently at which the matter was talked over. In a letter received from the Automobile Club of America there seem to be very little hope of having another international race, as the foreign manufacturers have agreed not to enter future races, but neither the A. C. A. nor the Savannah Automobile Club have given up the idea and everything possible will be done to have one held. Mayor Tiedeman will leave for Philadelphia on Tuesday and will go to New York, where he will talk with officials of the A. C. A.

WESTERN EDITION OF THE BLUE BOOK.

Robert Bruce, editor of The Official A. A. A. Automobile Blue Books, has just returned to Chicago, where he has been located with his staff for some time past editing the Western edition. Mr. Bruce has been preparing a series of trips from Chicago in every direction and has covered up to date over 6,000 miles of territory never before adequately described. In the meantime Blue Book Car No. 1, in charge of E. R. Mixer, is nearing Chicago through Ohio and Indiana, preparing and new revising main routes from the East. The new section of the "Blue Book" will cover Ohio, Indiana, Illinois, Michigan, Wisconsin and Kentucky, and will connect by the best roads the principal cities west of the Mississippi River.

BOSTON DECIDES TO HAVE 1910 SHOW.

BOSTON, May 17.—Success in such a large measure resulted from the 1909 show in Mechanics Building that the Boston Automobile Dealers' Association last week took official action in regard to the 1910 exhibition. The corresponding week of next March will be the date and Chester I. Campbell will again manage the affair. Reports of the last show have indicated that it was the most successful ever held, considered from any angle, the gate receipts were larger than usual, the general interest was greater and the effects are still being felt as a sales stimulus. The dealers have decided to take an active part in the Orphans' Day outing on June 9, and will take the blind children of the Perkins Institute on a trip to Sharon later in the same month.

ORPHANS' DAY IS APPROACHING.

Orphans throughout the country will have their annual automobile outing on June 9. This will be the fifth celebration of the day in some cities, and already preparations have been made for making the 1909 event the most memorable of them all. The automobile trade has always been a supporter of orphans' day, and this Summer a special campaign will be outlined to secure the machines from private owners as well as dealers and manufacturers. W. J. Morgan has the metropolitan outing in charge and it is his idea to present to the orphans' day committee a plan of having each make of car in the run fly a pennant with its name and number. This little feature is partly advertising and partly because nowadays the public is more interested in the make of the cars taking part than any of their entrants or drivers. The Quaker City Motor Club will engineer the celebration in Philadelphia and cars for nearly 1,000 children have already been promised. With plenty of cars at their disposal and plenty of small children ready to fill them, the committee expect to make the event one that will be long remembered.

What the Clubs are Doing These Days

COLUMBUS ASSOCIATION ELECTS OFFICERS.

COLUMBUS, O., May 17.—At the annual meeting of the Columbus Automobile Association, held in its club rooms recently, the following officers were elected: President, Max Morehouse; first vice-president, P. B. Monypeny; second vice-president, Dennis Kelly; secretary, N. O. Aeby, re-elected; treasurer, Herman Hoster. The club has arranged to start a series of short runs on Saturdays and Sundays, and the national orphans' day will be celebrated by taking the little folks to the Country Club. An automobile show will be held in the Fall.

ATLANTA'S CLUB NOW HAS FINE NEW HOME.

ATLANTA, GA., May 17.—The Fulton County Automobile Club is now well settled in its club house and is fortunate in the possession of a fine old country place. This house was built as a residence by one of Atlanta's wealthy citizens and when it was thrown on the market the club gobbled it up. The house is

Fulton County Automobile Club's House Near Atlanta.

located on the Peachtree road, about five miles from the city, and is situated far back from the road in a grove of fine old forest trees. It is fitted up with all the taste of the homes of the wealthy and cultivated and it is doubtful if any automobile club in the country has a more artistically furnished house.

WALLA WALLA AUTOISTS ORGANIZE.

WALLA WALLA, WASH., May 17.—Temporary organization of automobilists of this city was changed into a permanent one at a recent meeting attended by nearly all local autoists. The following officers have been chosen: President, Dr. E. E. Shaw; vice-president, J. W. Lankdon; secretary, Tom Drumbeller; treasurer, W. W. Baker; board of directors: T. A. Paul, Dr. E. E. Shaw, W. J. Corkrum, W. W. Baker, Tom Drumheller, J. H. Morrow, John Langdon, C. J. Bowers, Gilbert Hunt, George Kellogg, J. M. Crawford, E. H. Preston.

PROSPECTS FOR NEW CLUBS IN WISCONSIN.

MILWAUKEE, WIS., May 17.—The usual spring activity in club circles is manifesting itself now, and a number of new clubs are being formed. The commercial association of the Eau Claire is taking steps to form a club, which will affiliate with the State and national bodies. A number of owners at Lancaster are considering the proposition to form a local club.

CLEVELAND CLUB ACTIVITY—GOOD RESULTS.

CLEVELAND, May 17.—The Cleveland Automobile Club is at the present time taking a most active interest in autoing conditions in Cleveland and northern Ohio, and as a result is receiving the co-operation not only of motorists but of the police force, in addition to the state board of registration.

For some time there has been an epidemic of stealing in this city which the police have been powerless to prevent. After waiting some time for the police force to make a definite move, the Automobile Club stepped into the breach with an offer of a reward of $100 for the arrest and conviction of any one caught stealing an automobile *or any part thereof*, with the result that the thieves have grown wary and cars standing on the streets at night are now practically safe. "Joy riding" has been practically stopped by revoking licenses.

Perhaps the most important action of all those taken by the club relates to reckless driving and speeding. Threatened with the passage of an eight-mile-an-hour ordinance in all parts of the city, the club proceeded to join hands with the police and an effective campaign against law-breaking drivers is now on in full force. A bureau has been established at the club to assist in this work, and the club members are requested to send in the numbers of speeding cars. The owners of these cars then receive warning notices from the secretary's office, and after repeated offenses the numbers are voluntarily turned over to the police with a request that drastic action be taken. As a result of these crusades the club is coming into the limelight in northern Ohio, and the membership is increasing by leaps and bounds toward the 1,000 mark.

PITTSBURGH ACTIVE IN GOOD-ROADS WORK.

PITTSBURGH, PA., May 10.—Allegheny County roads are being constantly improved through the activity of the Automobile Club of Pittsburgh, in co-operation with the road supervisors and engineers. The influence of the club has been directed by George T. Barnsley, good roads engineer and chairman of the road improvement committee. The county is now spending about $1,000,000 per year for the purpose of bettering its highways, and 60 miles of macadam will be constructed this year. As a result of its interest in the supervisors there are now 15 road drags in use and reports show that the cost of keeping the roads has been reduced from $35 to $8.50 per mile, the drag needing only three men instead of six.

Secretary Wolff and other officials recently met with the supervisors of Mercer County, aiming to get the road from Mercer to Zelienople and Meadville macadamized. Mercer, 50 miles north of this city, is on the main route to Buffalo. The club will issue its road book on June 1, containing 110 routes in detail.

SAVANNAH ENDURANCE RUN TO BE MAY 31.

SAVANNAH, GA., May 17.—The next event of interest to the automobilists of this vicinity will be the endurance run to Augusta and return, a distance of 132 miles each way. The Automobile Club at a recent meeting decided to hold this on the last day of the month, starting at seven o'clock in the morning.

It is not to be in any manner a speed test, but endurance will be the standard by which merit will be measured. It is likely that twenty cars or more will make the trip and the car with the least stops will be rewarded the trophy. Secretary Arthur Soloman was given the duty of preparing a list of penalties which will govern the run. Another point of interest brought up was that ladies would be allowed to make the trip.

Ben Noonan, Winner of the Santa Rosa Road Race, Crossing Finish Line in His Stoddard-Dayton.

CALIFORNIAN RACE HAS A STODDARD-DAYTON WINNER

SAN FRANCISCO, May 10.—Under the joint auspices of the Sonoma County Automobile Association and the San Francisco Motor Club, the first road race in the northern part of California, held yesterday near Santa Rosa, had a Stoddard-Dayton as a winner. The course was 40 miles long, and a particularly hard one because of the many turns and the condition of the road surface. The first 15 miles constituted a very badly twisted "straightaway," with a number of turns at an angle of nearly 45 degrees. The road surface was rough for fast work, and that an accident did not occur is little short of a miracle. After this came the greatest test, in what was known as the "Loop." The road winds from Geyserville through the Dry Creek country, and back to the so-called "straightaway." It is full of sharp turns, many of them at the apex of steep grades.

Twelve cars started, eleven of which practically came to grief, although six reached the finishing line. The honors of the day went to the Stoddard-Dayton, entered by A. D. Plugoff, and driven by Noonan. The elapsed time of the winner was 1:05:18, which won for it the $500 trophy. The Moore Motor Supply Company's trophy, which was second prize, went to the Stevens-Duryea, entered by the Pacific Motor Car Company, and driven by C. Ontank. He covered the course in 1:07:30, despite trouble encountered. In the loop the car crashed into a fence and cracked the frame, which broke when driven over the rough ground on the homestretch. Ontank finished, however, and crossed the line in second place. The Stoddard-Dayton, which came in third, was driven by Fred Wiseman, who lost time in recovering a battery which dropped off. Fay Sheets, at the wheel of the Acme, drove the last 17 miles on the rim of the left front wheel from which the tire had been thrown. He swayed and careened over the finishing line, having covered the course in 1:11:37 1-2. The Buick, which arrived fifth, came to grief through a broken gasoline feed pipe, caused by hammering over the rough roads. Several minutes were spent in repairing the pipe, and the car's elapsed time was 1:15:12 1-2. The Tourist, a California-built car, entered by H. W. Bogen, came sixth.

It was a fine day for the spectators, but a most expensive contest for the owners of most of the cars that participated. The course was patrolled by a squad of the State militia, assisted in handling the immense crowd by the supervisors of Sonoma county, the police of Santa Rosa, and the officers of the two automobile associations.

Those who had charge of the event were: Starter, William R. Johnston; assistant starters, Captain Fred A. Marriott, Jr., W. B. Morrell; clerk of the course, A. D. Plugoff; chief timer, P. F. Gillette; timers, W. B. Lloyd, W. W. Peterson, William Pedlar, William Hinklebein; judges, Fernando Nelson, William M. Klinger, J. H. Gray, J. W. Griffith, R. R. l'Hommedieu; referee, C. C. Donovan; contest committee, Don C. Prestiss, chairman, and J. R. Leppo.

CHICAGO'S ROAD RACES ARE RAPIDLY FILLING

CHICAGO, May 17.—Entries to the Chicago Automobile Club's races, set for June 18 and 19 over the Crown Point-Lowell course, will close officially June 5 with Frank H. Trego, although provision is made for possible stragglers by giving them five days of grace in which they can enter upon payment of $250 extra per car.

At the present time there are sixteen actually in hand—eight in each race—while the outlook is that there will be twenty at least in each contest, General Executive Trego having a long list of prospectives. The last name to be added to the entry list was that of Knox, which has named two cars for the Cobe cup, the blanks for which came to hand Saturday. This was preceded earlier in the week by the nomination of a Fiat by E. A. Hearne, of Chicago, the owner of the car, and who already has had racing experience through having been a competitor in the light-car race at Savannah. The Isotta, Benz and Renault also are on the likely list, while it is reported that Apperson and the Locomobile will be in inside of a week. The Pennsylvania is counted on for two, while the Thomas people are now tuning up a 1910 little six. As the list now stands there already are in the Cobe race two Knoxes, two Stoddards, three Buicks and a Fiat.

In the light-car event there are the Moon, three Buicks, two Stoddards and two Marions, the last named having been nominated earlier in the week. Two Chalmers-Detroits are expected.

As a result of a careful odometering of the course by General Executive Trego, it is announced by him to-day that the circuit is exactly 23.6 miles in length. In the Cobe cup race the cars will make seventeen laps and in the Indiana trophy ten laps.

CHANGES IN YORK COMPANY PERSONNEL.

YORK, PA., May 17.—President S. E. Baily and General Manager and Designer James A. Kline have severed their connections with the York Motor Car Company, manufacturers of Pullman automobiles. For some time this move has been rumored in automobile circles, but has just been announced officially and a number of changes have thereby been made. Mr. Baily withdrew recently and Mr. Kline on Saturday, selling part of their stock to New York parties and retaining some, it is understood. The report that the General Motors Company was interested is said to be unfounded, and the local concern will hereafter be directed by Oscar Stevenson and Thomas C. O'Connor, formerly secretary and treasurer and vice-president, respectively. The former will act as business manager.

Mr. Baily, who has an extensive business in carriage building, has started the erection of a new concrete automobile factory in which commercial cars will be built at first, and then the lines of pleasure cars added.

As general manager and designer Mr. Kline has contributed largely to the success of the York company, bringing it to a point where the supply of Pullman automobiles is less than the demand. He has propositions from a number of automobile concerns which he is considering. At present he is attending to private interests in this city and Harrisburg. As the entrant of Pullman automobiles in all of the important track and endurance contests of the east, aside from his business relationships, he has gained a wide acquaintanceship among the trade.

TRACY TESTS NEW DIAMOND RIM AND TIRES.

As a preparation for the Cobe trophy race, and to give a critical test to the new demountable rims developed by the Diamond Rubber Company, Joseph Tracy recently made eight laps of the 1908 Vanderbilt race circuit, maintaining an average speed of 60 miles an hour, and reaching a maximum of 92 on the motor parkway. According to his report, as issued by the Diamond company, the new rim and the Diamond grip tire for racing and anti-skidding work, after going through the mill of every kind of a test Tracy's experience could suggest, were not affected. The tire casings were not materially injured and the rim in the same condition as at the start. No change of tires was necessary in the entire eight laps, and on the full set not more than a score of steel studs were loosened. The car used was a 90-horsepower Simplex, and to demonstrate the time necessary to change tires, the car was brought to a quick halt from full speed at the end of the eighth circuit, and Tracy states that it took just 30 seconds to take off the tire and rim and place fresh ones on the wheel. This test has assured the Diamond company to its own satisfaction of the ability of the rims and tires, and an active participation in current races is planned.

MORE ADDITIONS TO RAMBLER FACTORY.

KENOSHA, WIS., May 17.—Enlargements now being made to the factory of Thomas B. Jeffery & Company in this city, when combined with those buildings to be erected within the next few months will give the plant an additional space of 186,256 square feet. Added to the present space, the total will be approximately 800,000. Rambler factory construction will be followed, that of one story, solid concrete structures, with steel frames, and sawtooth roofs. One building now under way, with an area of 98,688 square feet, will be devoted to inspection and exterior finishing departments; 41,120 will be the area of the addition to building number 7, used by the final inspection department, and number 5, the assembly and stock rooms, will secure 16,488 additional. The original Rambler factory, building 1, will be enlarged by the addition of 30,000 square feet, all of these together greatly increases the capacity of the plant. A new laboratory for testing materials will be installed, and within a year a new office building will be started.

THE DEATH OF DANIEL W. MARMON.

INDIANAPOLIS, IND., May 17.—Daniel W. Marmon, president and one of the founders of the Nordyke & Marmon Company, died at his home in this city last Monday, after an illness of seven months. Death was not unexpected as he had been in a serious condition for some time.

Mr. Marmon was born in Ohio, moving to Richmond, Ind., with his parents when two years old. After completing his education in the schools and Earlham college in that city, he purchased an interest in the firm of A. and H. Nordyke, manufacturers of flour milling machinery. This company was then reorganized as the Nordyke & Marmon Company and in 1876 moved to this city. When automobiles became used so generally a few years ago, the company was one of the first in the city to engage in their manufacture. Associated with Mr. Marmon in the business were his sons, Walter and Howard C., who with the widow and a daughter survive. The funeral services were held last Thursday afternoon.

The factory and down-town salesrooms were closed on Tuesday, Wednesday and Thursday. Mr. Marmon was also president of the Indianapolis Light and Heat Company.

PACKARD TRIES OUT THE ZEGLEN.

DETROIT, May 17.—That tire troubles are due to be reduced to a minimum if not entirely eliminated as the result of his invention is the confident prediction of a Chicagoan named Zeglen. Nor are his claims impaired any as a result of tests he has been conducting here, with the cooperation of the Packard Motor Car Company. Taking two heavy planks, Zeglen filled them with sharp pointed nails of varying lengths. On the back of each of these another plank was securely fastened so that the nails could not be pushed back. Then a Packard car equipped with Zeglen tires was run over these nail-studded planks, slowly and at a speed of twenty to thirty miles an hour. Singularly enough, the tires, which are made of bullet proof cloth treated with rubber and vulcanized, did not show the slightest effects of the hard usage to which they were subjected. More exhaustive tests are being arranged for the Packard people, while Zeglen is planning to erect a factory here for the manufacture of non-puncturable tires.

THIRTEEN ENTRIES FOR RUN TO SEATTLE.

NEW YORK, May 17.—Announcement has been made of thirteen entrants for the transcontinental endurance contest, which will start June 1 for Seattle. They are as follows:

FORD	Ford Motor Company.
FORD	Ford Motor Company.
ACME	Acme Motor Car Company.
STEARNS	Oscar Stolp.
SIMPLEX	Simplex Automobile Company.
SHAWMUT	Shawmut Motor Company.
THOMAS	Gus Buse.
RENAULT	W. G. Houck.
THOMAS	E. R. Schmidt.
FRANKLIN	S. S. Mapes.
WELCH	L. H. Perlman.
STEARNS	Chas. Watson.
GARFORD	Wally Owen.

Mills & Moore, the Eastern managers, have given out this list with the statement that several others may enter before the start. In the meantime the Thomas pathfinder has finished its survey of the roads around Boise, Idaho, and is now within striking distance of the finish. The Seattle authorities have about completed the building set aside for the cars which finish the contest.

NEW COMPANY FORMED IN CLEVELAND.

CLEVELAND, May 17.—Within a few weeks, the Cleveland Electric Vehicle Company, formerly the Cuyahoga Motor Car Company, will begin the manufacture of electric taxicabs. The reorganized concern is capitalized at $300,000, and Francis J. Wallace, formerly of New York, who floated the Citizens' Taxicab Company in this city, will handle the sales.

Pierce-Arrow Factory Additions.—When the new factory of the Pierce-Arrow Motor Car Company, at Buffalo, was completed about a year and a half ago, it was thought that it would be sufficiently large for a long period. The first addition has become necessary, however, and it will be to machinery hall, one story in height, 201 feet long and 50 feet wide, giving 10,500 square feet additional floor space. This will be utilized for the installation of new machinery and will give machinery hall a complete floor space of 92,705 square feet. The new section will be built of reinforced concrete. A second addition will be built to enlarge the body-building department. It will be 60 by 75 feet in size and three stories high, giving an additional floor space of 24,000 square feet and making that of the department 161,040.

Winton Self-Starter Holds Its Pressure.—The Winton Company is frequently asked whether the pressure on its self-starting system holds during long periods of inaction, and the following letter received from B. A. Armstrong, of New London, Conn., is cited as the experience of one owner. Mr. Armstrong says: "Referring to my new 1909 Winton, it is a fact that this car was jacked up in my garage late in December or early in January. My chauffeur says the pressure was 110 lbs. when we left it. I spent the Winter in Florida, returning on the 10th of April. A few days later we put the car in commission and we found the self-starter pressure was 90 lbs., and the car was started without cranking; in other words, the self-starter was in full operation after the car had stood nearly four months."

Palmer-Singer Makes Hard Run Across Desert.—Clarence E. Conent, of El Centro, Cal., has recently made a trip in his P. & S. Six-Sixty car, which is notable among the hard trips possible on the Pacific Coast. He drove from El Centro to San Diego, 260 miles, over trackless deserts, and then crossing the mountains. After a day in the latter city he returned to his home in a day, both going and returning without a mishap, part of the distance running where there was no road, and for the greater part where there was a mere outline of wheel tracks. The route is considered one of the worst in California, and generally impassable for automobiles. Mr. Conent's car is over a year old, and the two hard runs seemed to have no deleterious effects upon it.

Mrs. Ramsay Plans Transcontinental Tour.—Final preparations for a tour in her Maxwell car from the Atlantic to the Pacific are being made by Mrs. Alice R. Ramsay, of Hackensack, N. J. She expects to leave New York Cty on June 9 in her new 30-horsepower car, and hopes to reach San Francisco by July 15 over a route through Albany, Rochester, Buffalo, Toledo, Chicago, Cedar Rapids, Omaha, Julesburg, Cheyenne, Granger, Ogden and Reno. Accompanying her will be Mrs. N. R. Powell, Mrs. W. Atwood and Miss H. Jahns, all of Hackensack. Mrs. Ramsay is an experienced tourist, the president of the Women's Motoring Club of New York, and of the women's section of the Maxwell-Briscoe Motor Club.

Where the Old Cars Go.—"There has always been considerable mystery in the mind of the public where all the old cars go," says "Tommy" Forbes, sales manager for the Overland and Marion cars, "but for me this mystery was dispelled during a recent trip to the West. Hundreds of old-timers made back in 1901, 1902 and 1903 are being used there and are giving perfect satisfaction. I saw many rear-entrance cars, and it is no uncommon matter to hear the chug-chug of 'one-lungers.' Many beginners in the West are using these old machines and I find that many are finding a lodging place in the Y. M. C. A. and other automobile schools."

Credit Where Credit Belongs.—By a regrettable oversight in connection with the photographs taken by night, which were published in THE AUTOMOBILE May 13, the omission of the word "Bureau" from the copyright credit, attributed the ownership to the Technical Press, a printing concern in New York, instead of to the Technical Press Bureau, which makes a business of supplying articles on automobile and motor boat subjects. The three night photographs were taken by Harry W. Perry, and are copyrighted, but the daylight photos are not copyrighted, and the notice should not have appeared upon them.

Kokomo Concern to Make Carburetors.—The Planhard Manufacturing Company, of Kokomo, Ind., has been formed to manufacture carbureters and other automobile accessories. The officers are: President, W. D. Parr; secretary, W. B. Voorhis; general manager, F. L. Kingston; factory superintendent, C. H. Felske. Mr. Kingston has been connected for a number of years with Byrne-Mr. Felske has been with the Apperson Kingston & Company, of Kokomo, and

The De Lisser Trophy.

This handsome cup is offered by the president of the Ajax-Grieb Rubber Company for the Maxwell-Briscoe Motor Club's June Tour.

Brothers Automobile Company. It is expected that the new plant will be open about June 1 and will employ a force of 25 men.

Locomobile Company Will Increase Factory.—Plans have been made by the Locomobile Company of America for a large addition to its factory at Bridgeport, Conn. The new part will cover an area of 40,000 square feet and enable the factory production to be made 1,200 automobiles a year. It will be possible to add from 300 to 600 mechanics to the present force, and under the present plans the cost will be about $60,000. The wing on the north side will be continued three stories in height, of brick and steel construction, and ready for occupancy early in the Fall.

"Tailor-Made" Wind Shields.—From the fact that no two automobile makers use the same kind and size of dash, requiring the manufacturer of glass fronts or wind shields to keep on hand samples of all makes, the Banker Wind Shield Company, of Pittsburgh, Pa., has adopted the expression "tailor-made" as applicable to its products. These shields have to be made to fit each dash to a nicety, and to do this templates of all various sizes and widths have to be kept on hand, and necessitates fine machinery and manufacturing facilities.

Electric Vehicle Receivers' April Report.—The April report of the receivers of the Electric Vehicle Company covering business done shows sales of $87,819.35, with purchases of $35,902.13. The cash receipts were $247,526.69. There was derived from royalties under the Selden patent $150,382.70. The disbursements amounted to $203,601.97, one item of which is $40,270.45 paid to George B. Selden, and there was also paid over to the Licensed Association $61,840.95. The balance on hand on April 1 was $151,356.13, and on May 1 $195,280.85.

Novelty Manufacturing Company Will Issue Catalogue.—The Novelty Manufacturing Company, of Waterbury, Conn., makers of specialties in metal goods, announces that it will shortly issue a catalogue of automobile hardware and accessories. Its automobile department is now in charge of F. L. Cowles, formerly of C. Cowles Company, New Haven, and late executive secretary and treasurer of the National Association of Carriage Hardware Manufacturers. He is well known in both carriage and automobile lines.

Milwaukee Crippled Children Ride in Ramblers.—Milwaukee's blind, deaf, crippled and invalid children were given a theater party last week, and through the courtesy of A. W. Shattuck, manager of the Rambler Garage Company, of Milwaukee, the branch of Thos. B. Jeffery & Company, Kenosha, Wis., the little ones were given an automobile ride to the theater and another ride following the performance.

Enlarged Plant for Mayo Radiator Company.—Manufacturing of automobile radiators has so increased that the Mayo Company, of New Haven, has had plans

drawn for the addition of two buildings to its plant. The main one will be one story high, built of brick, 150 by 300 feet in dimensions, and the smaller one will be 40 by 60 feet, and used for a box shop.

According to Arthur Jervis: "Taxicab drivers in New York, where twenty blocks on the avenues measure exactly a mile, boast that on rainy days they can register a mile every seventeen blocks, on the asphalt, because of the skidding of the wheels."

Diamond Tires on Flag to Flag Car.—The Chalmers-Detroit car, which is acting as pathfinder for the flag to flag endurance run from Denver to Mexico City, is equipped with Diamond tires and Marsh quick-acting rims.

IN AND ABOUT THE AGENCIES.

Cleveland Adds to "Fifty Cars Sold Here."—Local automobile trade, which has had a war cry of "Fifty cars sold here," will have to change this, for another agent has come to town, and still another is expected shortly. The arrival is the agency for the United Motor Buggy Company, placed with the Auto Sales Company, the Hupmobile agent, at 1122 Chestnut street. The Schutt buggy, of Cincinnati, will soon be represented by the Weddell House Garage, the inter-State agent, on Frankfort avenue, N. E.

Premier, Philadelphia.—The most recent addition to the Quaker City's "Gasoline Row" colony is the Motor Company, which has secured the local agency for the Premier car, and will be exploited from large and handsomely appointed quarters at 132-134 North Broad street.

Dayton Rubber Company Opens New York Branch.—Under the management of Arthur L. Manley, a branch in New York has been opened by the Dayton Rubber Manufacturing Company at 1595 Broadway. Dayton airless tires will be handled from this location hereafter.

TAXICAB AND TRANSIT.

Mail Automobiles for Japan.—Advisability of transporting mail by automobiles is being investigated by the Japanese minister of communications, according to newspapers of that country. It is proposed to establish a system of distribution and collection in the principal cities at first, and to gradually extend that to distant points not reached by railroads. Tokio and Osaka will get the first of the cars and it is said that Tomijiro Oguri, a merchant of the former place, will act as a contractor to supply them. If the autos are imported they will be free of the 50 per cent. duty ad valorem now levied, but it is likely if the proposition is favorably considered that the cars will be constructed in Japan, only the motors, tires, coils, and a few parts being imported.

Plainfield to Metuchen, N. J.—On a 45-minute schedule a passenger, mail and package line has been instituted between Plainfield and Metucheon. via Oak Tree. Two cars of 20-passenger capacity will be put into operation immediately, with an additional one held in reserve for rush hours, and orders will be placed for larger machines to seat 36 people, with a double-deck arrangement. The distance is 9 4-5 miles and the machines have been tested over the route at a three-quarters of an hour headway, giving satisfactory results.

Nashville Gets the Habit.—Taxicab service is about to be instituted in Nashville, Tenn., by a company which has been formed there with a capital of $30,000. A number of cabs will be purchased very shortly and put into immediate use. The concern is composed of a number of wealthy business men, among them being Major E. C. Lewis, D. S. Williams, G. E. Bennie, Banks Bennie, H. S. Frazier and James Frazier.

Rome to Adairsville, Ga.—Capitalists of Rome, Ga., are planning to establish an automobile line between that city and Adairsville, a distance of 18 miles, over the fine roads of Bartow and Floyd counties. The railroad schedules are inconvenient, and two round trips daily are suggested for the autos.

Atlanta, Ga.—For the use of its fire department chief the city has appropriated $4,000, with which to purchase an automobile. A choice will be made shortly, and the car selected must have a body suitable for carrying two fire extinguishers and other apparatus.

Swarthmore, Pa.—A company has been organized to be known as the Swarthmore Service Company, and will run an automobile 'bus line between the station and the town.

PERSONAL TRADE MENTION.

William B. Hurlburt Will Remarry.—A marriage license has been issued in New York to William B. Hurlburt, manager of the New York branch of the E. R. Thomas Motor Company, and Miss Mary Elizabeth Malloy. Mr. Hurlburt and his former wife, Mrs. Charlotte Hurlburt were divorced in Detroit two weeks ago.

Peter Dumont, who was connected for over two years with the Pope-Waverly, and for five years as manager of the automobile department of the New York Studebaker branch, has joined the commercial vehicle forces of the Baker Motor Vehicle Company, with headquarters in the New York branch at 1788 Broadway.

A. S. Blair, who recently severed his connection with the Mar-Del Mobile Company of Baltimore, has accepted a position on the sales force of the Zell Motor Car Company, representative of the Peerless and Chalmers-Detroit.

O. P. Smith, who has been manager of the Studebaker electric department in Kansas City, Mo., has resigned to take a position as manager of the Hathaway Electric Car Company at 1606 Grand avenue of the same city.

Wallace C. Hood, well known in Baltimore automobile circles, has become the general sales manager of the Motor Car Company, the agent in the Monumental City for Thomas, Stevens-Duryea and E-M-F cars.

James Joyce, manager of the American Locomotive Company automobile department, who recently spent two weeks at the Country Club in Farmington, Conn., will, it is said, make his Summer home in that town.

Warren J. Shay, formerly salesman with the Denver agency for the Stearns, has taken a position as Cleveland salesman for the Gaeth Automobile Company, of Cleveland.

NEW AGENCIES ESTABLISHED.

Frontenac: Nassau County, L. I., N. Y.—Anton T. Smith, Motor Parkway Garage, Jericho turnpike and Tyson avenue, Floral Park, N. Y.

Pierce-Arrow: San Antonio, Tex.—Lumly-Wood-Browniee Auto Company, direct agent, formerly sub-agent of Houston Motor Car Company.

Babcock: Philadelphia.—Stoyle & Vogel, in addition to the American, Grout and Midland.

Jackson: Utica, N. Y.—C. H. Childs & Company, Lafayette and Seneca streets.

Chalmers-Detroit: Indianapolis, Ind.—Indiana Automobile Company.

Rambler: Atlanta, Ga.—Baynard Wellingham, 70 South Forsyth street.

Frontenac: Brooklyn, N. Y.—P. J. Forbes, 96 Schermerhorn street.

Brush: Plainfield, N. J.—Laing Machine-Auto Repair Company.

Mitchell: Lambertville, N. J.—O. M. Driscoll, East State street.

Haynes: Kansas City, Kan.—Seberlin & Boyd, 1 Fifth avenue.

Fuller: Boston.—E. P. Blake, Haymarket Automobile Station.

Hupmobile: Brooklyn, N. Y.—Parkside Automobile Station.

Gaeth: Minneapolis, Minn.—McAllister-Newgord Company.

Reo Leads the British Army a Merry Chase.

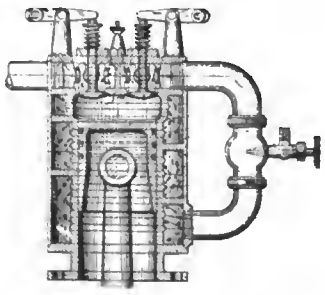
Reo car at the head of the parade of automobiles, carrying 1,000 soldiers from London to Hastings in the recent military tests of the utility of the automobile in time of war by the British Government.

SOME SELECTED AUTOMOBILE PATENTS

Issue of May 4, 1909.

920,167. Internal Combustion Engine.—John J. McIntyre, Hartford, Conn. Filed Feb. 28, 1907.

In this engine McIntyre has a new cooling scheme, the casing of the air-cooled cylin-

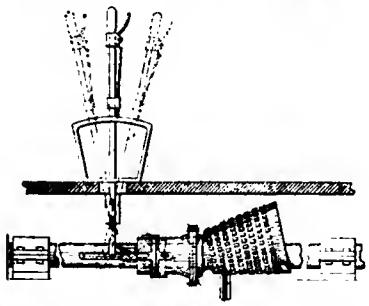


McIntyre's Air Cooling Scheme.

ders, which have extending flanges, being formed into a continuous and circular passage within which the air is circulated. The heated air as it finally emerges from this passage is sent to the carbureter.

920,190. Transmission Mechanism.—Benjamin F. Seymour, Denver, Col. Filed Dec. 12, 1907.

Here is a transmission device, which is capable of being carried out to great limits, thus providing many more speed changes than are now used. And still this is not a friction drive. An immense bevel gear, with

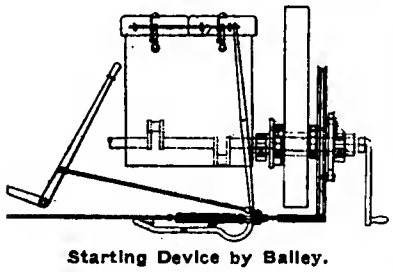


Seymour Multiple Speed Transmission.

teeth cut in rows so as to form a number of different bevels, is in mesh with a regular spur gear. The big cone-shaped gear is slidable, so that any desired combination may be had, thus giving any desired speed. Seymour also has his own method of securing the speed changes.

920,411. Starting Device for Explosive Engines.—Howard C. Bailey, Philadelphia, assignor to Elsie L. Bailey, Philadelphia. Filed July 12, 1907.

Bailey has a scheme here for starting by the pull of a hand lever, which releases a spring and at the same times causes a spark. The spring turns the engine over, and the spark fires the charge then drawn in and



Starting Device by Bailey.

thus keeps it turning over. No means being provided for correctly timing this spark, it is hard to see how it is to be effective.

920,257. Sparking Plug.—Ralph C. Browne, Salem, Mass., assignor to Browne Apparatus Company, Salem, Mass. Filed April 25, 1903.

920,289. Pneumatic Tire.—James W. Earnhart, Los Angeles, Cal. Filed Sept. 23, 1907.

920,326. Sparking Mechanism for Automobiles.—George S. Hill, Bradford, Mass., assignor to Hill Motor Car Company, Haverhill, Mass. Filed Nov. 20, 1905.

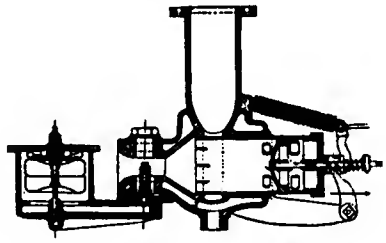
920,363. Transmission Mechanism.—Frank H. Merrill, Plainfield, N. J. Filed Feb. 3, 1905.

920,404. Resilient Hub for Wheels.—Albert E. J. Smith, Battersea, London, Eng. Filed April 3, 1907.

920,486. Vehicle Wheel.—Henry O. Jackson, Chicago, assignor to Jackson Wheel Company, Chicago. Filed June 6, 1908.

920,515. Starting Device for Explosive Engines.—Joseph Zagora, Chicago. Filed March 7, 1908.

920,642. Automatically Governed Carbureter.—Otto Pfander, Brussels, Belgium. Filed March 25, 1907.



Automatically Governed Carbureter.

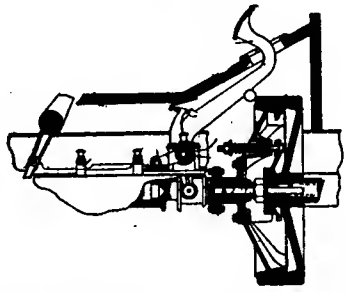
This is not as automatic as the title would lead one to think. The automatic part consists in the control of the auxiliary air supply. It is so connected up that any variation in the main air supply, by hand operated means is also exerted to change the auxiliary air ports automatically. Otherwise the carbureter presents no unusual features.

920,724. Electrically Operated Starting Device.—Haroid H. Brown, Boston. Filed July 27, 1907.

Issue of May 11, 1908.

920,916. Control Mechanism. Howard E. Coffin, Detroit, Mich. Filed April 13, 1908.

This is the clutch and change gear control of the Chalmers-Detroit 40, as now



Chalmers-Detroit Control System.

used. The clutch is a cone, leather faced, and its action is interlocked with the speed changes, and the shaft brake on the main drive shaft. The clutch action is also interlocked with the emergency brake lever, so that the application of the brake throws out the clutch.

920,979. Carbureter. Gardner E. Morehouse, Kansas City, Mo. Filed Jan. 25, 1908.

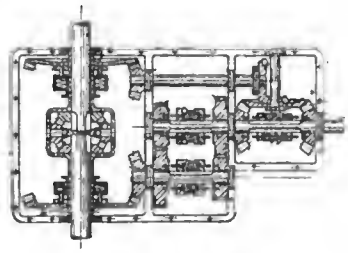
920,984. Vehicle-Wheel Hub. Thomas L. McConnaughey, Hagerstown, Ind. Filed Dec. 26, 1907.

920,989. Combustion-Engine. Oscar P. Ostergren, New York, N. Y., assignor to William M. Power, East Greenwich, R. I. Filed Oct. 15, 1904.

920,991. Valve Mechanism. Harry E. Perrault, Detroit, Mich. Filed Oct. 24, 1907.

921,035. Internal-Combustion Engine. Carl W. Weiss, New York, N. Y. Filed Oct. 14, 1907.

921,078. Speed-Changing Mechanism. Frederick C. Brunhouse, Philadelphia, Pa. Filed Oct. 24, 1908.



Individual Clutch Transmission.

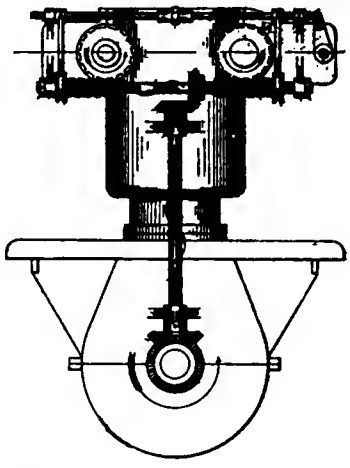
Brunhouse has here a new way of operating and constructing an individual clutch type of transmission. There are a number of clutches to be operated, too many in fact, as some of them appear needless. The transmission apparently gives more than the usual number of speeds.

921,174. Pneumatic Tire. William H. Synder, Kenton, Ohio. Filed Dec. 23, 1907.

921,233. Variable-Speed Mechanism. James A. Goodner and Albert P. Kendig, Rocky Ford, Col. Filed Sept. 23, 1907.

921,264. Gas Engine. Cyrus E. Mead, Dayton, Ohio. Filed March 25, 1908.

The recent agitation for rotary valves has stirred up the inventors and one of these, Mead, has an idea which appears to be all right. The two valves for the inlet and ex-



Mead Engine with Rotary Valves.

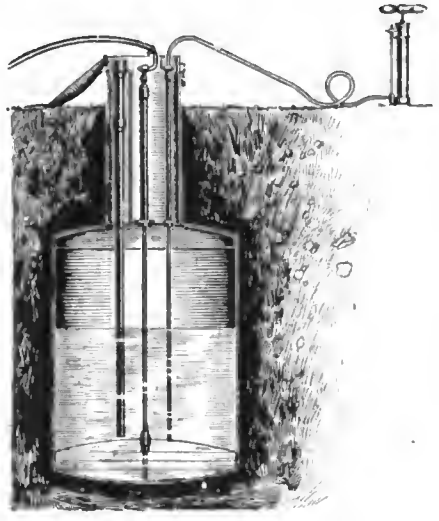
haust appear to be separate, which is different from the ordinary rotary valve, in which simplification is aimed at and attained by the use of a single valve for both.

921,283. Resilient Wheel. Jean Reuse and Charles Reuse, Hal, Belgium. Filed March 14, 1908.

921,491. Driving Mechanism, for Railway Cars. Rollin H. White, Cleveland, Ohio, assignor to the White Company, Cleveland, Ohio. Filed Sept. 14, 1906.

Information for Auto Users

Air-Tight Steel Tanks for Gasoline.—The action of the more progressive municipalities in specifying that all gasoline must be stored underground, has created an unusual demand for steel tanks suitable for this purpose. The Air-Tight Steel Tank Company, of Pittsburgh, report so large a demand for tanks that even with their large facilities for this class of tanks they have been unable to fill all orders. The equipment which is put out consists of an absolutely air-tight steel tank, made in one, two, three and five-barrel sizes, with brazed joints, no rivets nor solder, a superimposed dome, and fitted with a special lock which rises only a few inches above the ground after the tank has been properly placed in the ground, a supply pipe for filling, and a special pump for drawing the gasoline into the car or boat.



AIR-TIGHT STEEL TANK.

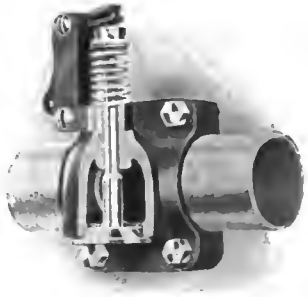
When the tank has been installed and the dome locked, it is not only almost invisible, but there is no odor as with an ordinary gasoline reservoir. For drawing the fuel out, the supply pipe is fitted with a rubber-tube extension, which conducts the gasoline directly into the reservoir. A similar rubber tube is connected with the special air pump, and by the operation of this pump forces the gasoline through. A few strokes of the pump is sufficient to raise a tank full. When this is full, the air in the tank is allowed to escape and as it does the surplus fuel is drawn back into the air-tight tank.

Hydraulic Windshields.—Emil Grossman Company, of New York, is marketing a new type of windshield known as the Hydraulic or Springaction, in which a feature is the set of cylinders and pistons which prevent the folding part from slamming and breaking. On each side of the shield is placed this device, as hydraulic, filled with oil or glycerine, or with a spring, and they operate automatically and positively, according to the makers. When the shield is either up or down, all that is necessary is to start it to the other position and the spring action does the rest. The procedure is much similar to that of door checks. The frame is made of heavy brass, with a filling-in board of mahogany or walnut. A sub-channel of copper lined with felt forms a cushion for the glass and does away with the rattle. The strip of brass across the middle of the shield at the dividing point is narrow.

Economy Garages.—Inasmuch as the problem of storing an automobile is a pertinent one with the prospective purchaser of a touring car or roadster, the use of private garages has become very popular. The Nicola Building Company, Farmers' Bank Building, Pittsburg, Pa., in a recent booklet issued, gives the details of its "Economy" garages, illustrated by blue prints and colored plates. These buildings are not portable ones; they are ready-made and permanent, fitted together before leaving the factory and giving the buyer only the work of assembling. They are made of wood, raised from the ground on solid supports, and of ample size. A work bench and a tool closet are included.

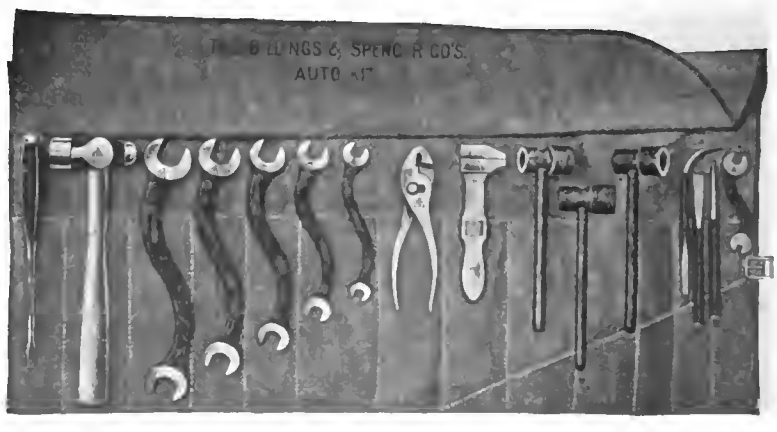
B. & S. Auto Kit.—A handy kit of tools for use on automobiles is being placed upon the market by the Billings & Spencer Company, of Hartford, Conn. The kit is made up of drop forged steel tools exclusively of the same high quality as, and selected from, the large variety of the machinists' tools manufactured by the company. It is believed that the selection in this kit will reach the needs of the average automobilists inasmuch as there is very little work done upon a car, except perhaps in shop overhauling, which cannot be handled by the B. & S. outfit. A well-made canvas bag is used to carry them, rolled up, and of such size as to fit snugly into a tool box. In the roll are the following instruments: a screw driver, nine inches long; a ball pein hammer, weighing 8 ounces; six full finished general service wrenches, with twelve openings varying in size from one-quarter of an inch to fifteen-sixteenths, by sixteenths of an inch, and if desired some other set of sizes may be substituted for this one; a six-inch pair of nickel combination pliers; a nickel monkey wrench; three double-end socket wrenches, giving six openings for nuts varying in size from three-eights of an inch to seven-eights, hexagon; a tool for pulling out cotter pins; a center punch: and a three-eighths of an inch cold chisel. This shows the comprehensiveness of the outfit, and the inclusion of a set of socket wrenches will be greatly appreciated by autoists who have tried to get nuts loose from difficult places by the ordinary monkey or S wrenches.

Novel Muffler Cut-Out.—Many an autoist has wished for a good cut-out valve, one that is so arranged as to prevent the destruction of the muffler in case of an accidental backfire, and yet is simple and easy to operate. These will be pleased to hear that such a device is now put on the market and may be obtained from any dealer. It is the Clamp valve, made by the Motor & Manufacturing Works Company, Geneva, N. Y. The name is given to it because it may be applied without taking anything off, as the construction is such that it clamps over the pipe. The valve is arranged to open outward, and in the event of a muffler explosion, this will open and allow the gases to escape. Thus, it acts as a safety valve as well as a cut-out valve.



CLAMP VALVE FITTED TO PIPE.

The yoke which carries the lever is free to turn around the valve stem and is then held in the desired position by means of a set screw. This allows of setting the lever so that the pull from the foot pedal is always in a straight line, and obviates the necessity of a pulley in this line. The valve will work equally well in any position, and is designed to meet the requirements of the repair man, or to be used wherever it is necessary to attach a cut-out valve to an engine on which the piping is already connected. It is made in all sizes from 1 inch piping up to 3 inches, and other larger sizes will be made to order. The only work necessary to attach one of these is to cut a V-shaped notch in the pipe with a hack saw before clamping on the valve, which is simply a matter of bolting in place.



BILLINGS & SPENCER AUTO KIT, WITH A FULL SET OF WRENCHES.

VOL. XX NEW YORK—THURSDAY, MAY 27, 1909—CHICAGO No. 21

THE AUTOMOBILE

IN TWO DAYS, FROM NORRISTOWN, PA., TO HAGERSTOWN, MD., AND BACK—373.9 MILES

BY G. M. SCHELL

Near Chambersburg, Pa., Where Horses Are Still Receiving Automobile Education—American Leading the Procession.

NORRISTOWN, PA., May 24—Popularity of automobile endurance contests, when the components include a beautiful and interesting course, a good system of computing the abilities of the participants, and a classification which invites the private owner as well as the trade to join, gave last Tuesday and Wednesday, May 18-19, the occasion being the second annual touring event of the Norristown Automobile Club one of the largest lists of any affair of its kind ever held. Fifty cars left this city for picturesque Hagerstown, in Maryland, a distance of 168.1 miles, on the outbound route, and 205.8 on the return. The rules for the manufacturers' and dealers' classes made the test a rigorous one, for it included a time schedule for these classes and the contestants not affiliated with the trade, so that with the technical examination at the conclusion definite winners were secured. T. Warren Berger in his six-cylinder Oldsmobile tourabout and Frank H. Yerger in a Studebaker roadster have been announced as capturing the honors in their respective classes of the real endurance run with the critical inspection, while in the class for club members, who had to keep to a time schedule only, there is a four-cornered tie between George Parker's American, P. V. Hoy's Pierce-Arrow, Frank Hardart, Jr.'s, Elmore, and J. Elwood Lee's Cadillac. Of the non-contestants, there were ten, and as each one of these finished in good form, satisfactory to the judges, it was given a certificate of perfect performance.

SUMMARY OF NORRISTOWN RUN.

No.	Car.	Class.	Driver.	Points Lost.
2.	Oldsmobile	A-1	T. W. Berger	.2
24.	Studebaker	B	F. H. Yerger	4.4
32.	American	A-2	G. P. Parker	0*
33.	Pierce-Arrow	A-2	P. V. Hoy	0*
40.	Elmore	A-2	F. Hardart, Jr.	0*
41.	Cadillac	A-2	J. E. Lee	0*

*Not examined technically.

The road conditions were such as to furnish a thorough trial of the automobiles, and the method of arranging the schedule one which made it imperative for the drivers to run more consistently than many are accustomed to doing. Fine State pikes, good but dusty country roads, rough mountain paths, and plenty of climbing over the Blue Ridge mountains featured the route to the famous Maryland town, and valleys whose roads abound in waterbreaks were traversed on the return. The average speed required was either the maximum allowed under the

Matheson Third in the Big Class.

law, or very nearly that; and, in addition, there was the stipulation that the drivers were allowed not more than ten minutes' leeway between each control, the remainder of the time being taken up in actually moving forward. This prevented racing, and towards the end of each control very often necessitated a snail's pace. Dry weather favored the contestants, for in many places the roads were such as would have been well nigh impassable had there been rain.

Nineteen perfect scores were held at the completion of the first

Franklin a Close Second in Class A.

lap out of the thirty-one in the time contesting classes in the morning. Five were eliminated from this list on the second day, so that when the event ended in this city there were eight tied in the main class for touring cars or tourabouts, two among the runabouts or roadsters, and the four in the club members' contesting division. The technical examination was sufficient to make a decided change, however, giving the Oldsmobile the Block trophy, the Studebaker the Club trophy, and the four who claimed equal title to the Contestant's Club trophy arranged to leave it in the custody of the club, with the proposition of competing again for it in the annual contest next year.

Although the technical committee had decided to make no announcements as to the nature of the technical penalties, it became known that the .2 of a point imposed upon Berger was for a loose chassis bolt; that the 4.4 demerits set against Yerger were for loose cylinder nuts and pan bolts; that the 2.1 against Carris, who took second place among the touring cars, was for loose spring clips, leaky sight feed, and a loose chassis nut. A slight looseness of the steering wheel gave Hall's Matheson 4.2 points, putting it in third place, and a loose crackcase bolt and a loose steering connection sufficed to give the Interstate 28.8 and fifth position. Harry Walls' Oldsmobile passed an excellent examination, being penalized only 6.7 points, but a road mark lowered its standing. Of the enormous total of 300.4 against W. T. Taylor's six-cylinder Oldsmobile, all but .4 of a point

Studebaker Which Captured Class B.

was registered against him for having lost his acetylene gas tank. It was picked up on a long hill below Pottstown and traced to his car in the examination.

Walter M. Cram, whose Mitchell "30" was the only other clean score in addition to the Studebaker among the runabouts, was penalized 37.1 points mainly for a damaged rumble seat and a loose steering connection. Crawford's 18-horsepower Franklin in the same class had 18.6 points against it, but a road penalty put it into third place. A special contest between Van Peacock, driving Perry Gresh's 15-horsepower Ford, and Joseph Graham, in his own car of the same make and model, was declared a draw, for both cars made the run on time and without adjustments of any kind.

En Route to Hagerstown Over the National Pike.

Scenic beauties of the trip had been talked of as much as had the contesting nature, so that the tourists had an additional interest on the run through the southeastern part of the State, skirting the Hundred Mile Woods, in which Washington and his Continental army spent a gloomy winter; then through the fertile Lancaster valley, considered to be one of the richest sections of the nation; bending southward after crossing the long bridge over the Susquehanna at Columbia; through York, civil war country around Gettysburg, right into and over the mountains which had been sighted long before, and finally dropping right into Hagerstown for the night. There was the usual tale of road experiences to be heard, for enough had happened to cause the fading away of a dozen clean record possibilities. A.

LaRoche headed the list in T. W. Twining's Regal, which struck one of the many bad ruts near York and snapped a front spring, an occurrence that is not uncommon to the autoists of that section, and thirty miles further on the other front one went down under the extra strain. A fence rail and a sledge hammer improvised a repair that enabled the Regal to reach all but the last control on time, and during the night a new set of springs were procured, so that the car finished the run on Wednesday without further mishap as a non-contestant. Taylor, in the Oldsmobile, ran out of gasoline in the mountains, a mile and a half from nowhere, and 43 points penalty piled up. The Kissel-Kar lost 29 points, 18 of which was for time lost in consequence of the motor's stalling on a sharp up-grade. Five marks were placed against the midland.

Class B for roadsters and runabouts driven by manufacturers' representatives had a number of its contestants scored upon. The little Maxwell Junior, which made a 3,000-mile non-stop run around Philadelphia during the winter, suffered greatly from tire trouble and caused the contest committee much consternation when it was found that the observer had mixed up his records, and it was necessary to give its score as incomplete. It was driven by W. C. Longstreth. The scores of the two Middleby cars were also listed as incomplete. The Brush single-cylinder runabout, the lowest-powered in the run, driven by D. T. Busse, had to stop at Hanover for seven hours because of a loose connecting rod bearing, but a new one was secured from York. Then the road through the mountains was lost and the car reached Hagerstown just in time for breakfast and to check out on the second day's run. There were loud calls for a more rigorous schedule for the return trip at the meeting of the contestants after the arrival at Hagerstown, and it was decided that the maximum should be given for the run to Norristown.

The checking stations on the outward bound run were established as follows, with the distance between each: Norristown to Coatesville, 29.4 miles; Lancaster, 27; York, 24.4; Hanover, 21.5; Frederick, 39.3; Hagerstown, 26.5; total, 168.1 miles. The running time for division I cars was 8 hours and 33 minutes, and for division II cars was 9 hours and 42 minutes.

Route Had Scenery in Profusion—Mitchell Second in Class B Passing the Committee Car.

Return Through Harrisburg and Famous Valleys.

With prospects for a run of 205.8 miles before them the contestants were lined up at an early hour for the return trip. Again there was scenery ahead which made the run well worth while, if for no other reason, through the battlefield of Gettysburg, then up the famous Cumberland valley to the State capital, and across from the Susquehanna valley to the Schuylkill at Reading, thence to the finish. Inasmuch as Hagerstown is right in the heart of the Blue Ridge, it was necessary to do some steep climbing to get out of it. Jack's Mountain was the first encountered, and it was so near the start that a number of the second division cars with a comparatively easy schedule blocked the contestants in the first section who had not gotten an early start, and were wanting to make up time. The beautiful Cumberland valley was nearly obscured to the tourists because of the heavy pall of dust raised by the caravan, varying in color from white to red, to gray, or brown, depending upon the color of the roads, and the cloud was so nearly impenetrable that one machine could hardly get near enough to another to pass with safety. From the capital to the Berks county metropolis, Reading, the run was just a pleasant amble, and the result was that the party reached that city in a bunch. There was a surprise in store for them, however, in the route between Reading and Pottstown, for the usual one was not followed, and in its stead the cars were taken down through Birdsboro, along the banks of the Schuylkill and of a canal. The road wound around the latter so much, and so many times crossing on short bridges high up in the air, with sharp approaches and still steeper descents, that for a time drivers were worried.

The only accident of the trip occurred to the Kissel Kar soon after leaving the Harrisburg control, when it had a collision with a wagon and a steering knuckle was broken. The driver, W. H. Rodgers, observer Kirkbride and passenger Aschenfelter were thrown out, and Kirkbride lost several teeth, while the others were badly shaken and bruised. They were attended to by the Red Cross party in Paul Huyette's Peerless. W. J. Sprankle's Fiat was one of the first to suffer, a rear axle breaking on Jack's Mountain, causing the withdrawal of the machine from the contest. The four-cylinder Oldsmobile, driven by Walls, had carbureter trouble, which made it late at several controls; and the six-cylinder Oldsmobile, driven by Taylor, lost its gas tank, which told its tale later, although the car had a clean record for the day. The little Maxwell, driven by Longstreth, had another succession of tire troubles, and, with eight punctures, it was seriously delayed several times. The last five miles were finished on one rim and the machine withdrawn. The Midland, Franklin runabout, two Middlebys, and Pope-Toledo were penalized.

Elmore, One of Tied Four in Club Trophy.

Incomplete scores were given to Detweiler's Overland, Ballard's Franklin, and Miller's Chalmers-Detroit. These were caused mainly by the inexperience of observers, and were considered by many as real reasons for the adoption of rules which would penalize the car appointing the observers rather than the machines in which they rode. The Mitchell driven by Jacob Beideman butted into a curb while maneuvering for the start in the morning and broke a steering cross rod. The car was withdrawn.

The checking stations and distances of the second day were: Hagerstown to Gettysburg, 35.4 miles; Chambersburg, 24.9; Harrisburg, 51.8; Reading, 54.7; Pottstown, 18.5; Norristown, 20.5; total, 205.8 miles. The running time for division I was 10 hours and 20 minutes, and for division II was 11 hours and 45 minutes.

The technical committee took the division I cars in charge as soon as they checked in for the examination, and this was completed on Friday, when the results were compiled and the winners announced. An interesting feature in connection with the trend towards larger wheels was seen in the tire conditions of the winning Oldsmobile, with 42-inch Goodrich tires. These were used throughout the recent grueling test of the Harrisburg club and had covered a large mileage previous to that, and then previous to this one, but the car went through both events without touching the tires, and the shoes do not seem a bit the worst for the wear.

Many women participated in the run, among them being Mrs. J. S. Rex, Mrs. L. E. Taubel, Mrs. S. E. Ballard, Mrs. William Mogee, Mrs. J. F. Boyer, Miss Skillman, and Mrs. Crissman. Lunch was given to the tourists by the Motor Club of Harrisburg and appreciated by the entire party. At Hershey, thirteen miles east of Harrisburg, the cars were pelted with boxes of Hershey chocolate.

The official cars were donated by the following: Pilot, Winton, A. E. Maltby; referee, American, Stoyle-Vogel Auto Company; red cross, Peerless, P. B. Huyette; starter, Matheson, W. W. Davis; checkers, Autocar, Autocar Company; press, Locomobile, S. deB. Keim.

Reading's Club Generously Supplied Refreshments.

SUMMARY OF ROAD AND TECHNICAL PENALTIES.

CLASS A—DIVISION I—TOURING CARS—Block Trophy.

No.	Car.	H.P.	Cyl.	Driver.	Road Penalties. 1st Day.	2d Day.	Tech'l	Total.
2.	Oldsmobile	60	6	T. W. Berger	0	0	.2	.2
13.	Franklin	28	4	C. S. Carris	0	0	2.1	2.1
14.	Matheson	50	4	A. D. Hall	0	0	4.2	4.2
3.	American	50	4	Samuel Truitt	0	0	26.7	26.7
5.	Inter-State	35	4	D. F. Templeton, Jr.	0	0	28.8	28.8
10.	Cadillac	30	4	F. L. Paxon	0	0	30.4	30.4
12.	Buick	30	4	C. W. Mann	0	0	37.8	37.8
9.	Oldsmobile	36	4	H. E. Walls	0	39	6.7	45.7
4.	Midland	35	4	E. O. Hayes	5	11	34.6	50.6
7.	Jackson	30	4	W. J. Hayes	0	0	100.0	100.0
8.	Oldsmobile	60	6	W. T. Taylor	43	0	300.4	343.4
6.	Fiat	45	4	W. J. Sprankle	0	Withdrawn.		
11.	KisselKar	40	4	W. H. Rodgers	29	Withdrawn.		
1.	Regal	30	4	A. La Roche	Out first day, broken spring—continued.			

CLASS B—ROADSTERS AND RUNABOUTS—Club Trophy.

24.	Studebaker	40	4	Frank Yerger	0	0	4.4	4.4
22.	Mitchell	30	4	Walter Cram	0	0	37.1	37.1
23.	Franklin	18	4	W. Crawford	0	42	18.6	60.6
27.	Middleby	28	4	E. Smith	Incomp.	48	87.6	135.6
25.	Middleby	25	4	H. L. McCullough.	"	97	98.8	186.8
26.	Brush	7	1	D. T. Busse	Broke down first day, but continued after repairs.			
21.	Maxwell	10	2	W. C. Longstreth.	Incomp.	Withdrew.		

CLASS A—DIVISION II—Contestant's Club Trophy.

32.	American	50	4	George Parker	0	0	*	0
33.	Pierce-Arrow	50	4	P. V. Hoy	0	0	*	0
40.	Elmore	35	4	Fk. Hardart, Jr.	0	0	*	0
41.	Cadillac	30	4	J. Elwood Lee	0	0	*	0
37.	Pope-Toledo	50	4	Alan Wood, 3d		97		97
38.	Mitchell	40	4	J. Beideman	0	Withdrawn.		
39.	Overland	30	4	W. H. Detweiler	Incomplete.			
43.	Franklin	24	4	S. E. Ballard	Incomplete.			
45.	Chalmers-Det.	28	4	W. G. Miller	Incomplete.			
35.	Crawford	30	4	A. H. Roop	Withdrawn at Hagerstown.			

* Not examined technically.

CLASS B—NON-CONTESTANTS' CERTIFICATES.

51.	Mitchell	30	4	R. A. Jackson	Perfect.
52.	Overland	40	4	J. Frank Boyer	Perfect.
53.	Buick	18	4	Tom Smith	Perfect.
54.	Overland	30	4	Frank Heavener	Perfect.
55.	Buick	30	4	F. Hamill	Perfect.
56.	Locomobile	40	4	H. Beideman	Perfect.
57.	Locomobile	35	4	Jos. Coulston	Perfect.
58.	Ford	15	4	J. N. Cassell	Perfect.
59.	Ford	15	4	H. K. Kalas	Perfect.
60.	Overland	30	4	W. G. Dyer	Perfect.
61.	Autocar	28	4	Sewell Crissman	Perfect.

MATHESON GETS WASHINGTON'S BIG PRIZE.

WASHINGTON, D. C., May 22—No. 13 Matheson, entered by William Orme and driven by W. B. McBurney, one of the Matheson factory experts, has been declared the winner of Class A in the reliability contest of the Automobile Club of Washington, held May 15. At the conclusion of the run, No. 4 Packard was declared by the technical committee to have finished with a perfect technical and road score. Against this decision a protest was filed, making certain allegations, one of which was that the driver of the Packard had to do some work on his car before he was able to start it. This protest was heard by the technical committee and resulted in four points being marked against the Packard for carbureter trouble. This decision was unsatisfactory to the entrant of the No. 13 Matheson, and he protested to the American Automobile Association.

Subsequently the Packard was withdrawn by its entrant, the Luttrell company. The protest of Mr. Orme, filed with the A.A.A., was thereupon withdrawn, and the Class A Trophy was officially given to the Matheson. The mix-up relative to the winner of the top-notch class has caused considerable hard feeling, but it is believed this will be overcome in time.

Wrights Will Fly at White House—In connection with the exercises incident to the presentation of the Aero Club of America gold medals to the Wright brothers, it is possible that they will consent to giving one or two flights on the White House grounds on that date, June 10. The aviators have signified their willingness.

CHICAGO, May 24—Progress in the promotion of the two road races of the Chicago Automobile Club—for the Cobe cup and the Indiana trophy—is rapid, and there is every reason to believe the events of June 18 and 19 will be huge successes. Rules were completed last week, the Lewis company is hurrying to complete the work of resurfacing the course; Colonel Sanborn has mapped out his plans for the policing of the circuit with the First Regiment of the Illinois National Guard; the sale of seats, which was thrown open to the public this morning, is good; President Cobe has received a wash drawing of his trophy, and the entries give promise of big fields.

Up to this morning there had been received in all nineteen entries, of which nine are Cobe cup candidates and ten are in the curtain-raiser. The last to come in was an Apperson Jackrabbit, nominated by Edgard Apperson, who names Herbert Lytle for driver. This is one of the two that will run for the Kokomo concern, it being the intention to make the other nomination at the end of the week. The Apperson goes on the same tab that already includes three Buicks, to be driven by Strang, Chevrolet and Burman; two Knoxes, to be driven by Denison and Bourque; two Stoddard-Daytons, with Miller and Englebeck up; and a Fiat put in by E. A. Hearne, who intends driving himself. In addition there are expected a couple of Locomobiles, and perhaps a Thomas little six. Two more Fiats are possibilities. No new entries have been received for the light car event since the two Chalmers-Detroits were turned in last week, but it is expected that a Corbin and a pair of Locomobiles will come to hand before the lists close. The ten in now are the two Chalmers-Detroits, two Stoddard-Daytons, three Buicks, two Marions, and a Moon.

Visitors to Crown Point yesterday found that the work of scraping the circuit has been nearly completed. The new stretch on the north leg is ready for rolling, while three miles of the east leg has been completed. In all, seven miles are ready, except that four miles must be rolled. This is on the east leg, and also on the stretch between Crown Point and Cedar Lake. There are two gangs of men at work. The one fixing the road includes thirty teams and thirty helpers, while in the taroid gang are twenty teams and fifteen helpers. In addition there are two scrapers, two steam rollers and a sweeper.

Colonel Sanborn figures out it will take 800 members of the First regiment to patrol the course, and in his plans he calculates on dividing the circuit up into three zones, in which there will be forty-one stations. In the first zone stations 1 to 9 will be included, and also No. 41. A major will be in command and the section will include the grand stand site and also the congested streets of the town of Crown Point. Three hundred men will be needed for this one zone. As many more will be required in the second zone, which will include the district in and about Lowell, with a major in charge. In the third zone the Cedar Lake district will be included, while the other stations will be in the country, the district being divided so that each squad will include eight men in charge of an officer.

The regiment will be moved to Crown Point the night of June 17 and will pitch its camp in the rear of the grand stand. There the soldiers will live during the meet, and it is expected they will add a picturesque touch to the landscape. Each morning they will be distributed at their stations by means of motor trucks, which General Executive Trego is securing for the purpose. Also there will be half a dozen motor ambulances.

The Cobe trophy, a design for which has just been shown, is of an unique nature. It will stand 39½ inches and be of sterling silver. The base is to be of malachite marble, which in turn stands on an ebony base. The base consists of a convoluted section of Ionic design, surrounded by miniature winged motor-car wheels, sprinkled with sprigs of laurel and oak. Ionic plates with appropriate wording appear on the front and reverse of the trophy, one bearing the inscription, "The Cobe Trophy, Western Stock Chassis Race," and the other being left blank for the names of the winners. Above the broad frieze which surmounts the base is an allegorical depictment of the Spirit of Speed, which includes the nude figure of a woman with wind-blown hair, seemingly gliding through space. Her left hand rests lightly on the surface of the urn, while her right arm is outstretched to cleave the air before her. Swallows, with wings outspread, accompany her. Below the mouth of the urn is a circlet of laurel leaves.

Prominent Drivers for Fal-Cars.

CHICAGO, May 24—With the nomination of two Fal-Cars for the stock chassis race in connection with the carnival to be held on the Crown Point, Indiana, course, two drivers of prominence have been added to the lists. E. M. Harrison, who has raced Darracq, DeDietrich, and Mercedes cars in famous English and Scotch races, will be at the wheel of one of the Fal-Cars, and A. H. Pearce, who was well known as a driver of Pullman cars, will have the other. Both Pearce and Harrison are now familiarizing themselves with the circuit and preparing their racing cars. H. R. Averill, the sales manager, has outlined a policy which will keep the new cars before the public.

President Ira M. Cobe of the Chicago Automobile Club.

Connecticut Reliability Replete with Perfect Scores

Renault Perfect Score Leading the Procession on the Beautiful Connecticut Highway.

HARTFORD, CONN., May 24—Reliability is a term well revered and understood in the central part of the Nutmeg State since the second annual endurance or reliability contest of the Automobile Club of Hartford. The hope of securing definite winners in each of the five classes had led the club to select a course of 213 miles which was considered hard enough to eliminate the usual preponderance of perfect scores, but the reliability of the 26 starting autos was a point previously underrated, for 15 finished with their records clean and there was a winner in but two of the divisions, those for the very smallest runabouts and for the very largest and most expensive.

Road and weather conditions combined in furnishing a test of real merit, and the drivers will testify as to its rigidity, but nevertheless there was a tie of unusual proportions when the event was completed in the dust of a dismal evening. Outlining in their course the figure of a four-leaf clover, the contestants were sent out of this city four times, each in a different direction, and were sent far enough away to give them all kinds of Connecticut highways, from the fine ones constructed by the State to the poor country roads yet unimproved, and each time bringing them back to the capital so that the interest in this city might be increased five-fold. Rain throughout the trip made traveling rather disagreeable and necessarily more difficult over a route considered strenuous even in dry seasons. These features, therefore, made it all the more of a surprise that there was not a dearth of the clean score genera.

Conducted under the A.A.A. rules, the cars were divided by their selling price, and a running time of ten hours given to the largest entrants, with that for the others arranged upon a handicap basis, so that the average speed required was between 17 and 20 miles an hour. There was a schedule of penalties for road work and for stalling of motors, but there was no technical examination—this not being thought necessary when the route was decided upon. The list of contestants was one that included well-known makes of American cars and one foreign representative. Yet of all there were just two definite winners after the run was concluded, a little Maxwell Junior obtaining an unqualified hold upon its class, for it started with one competitor and finished with none; and the other was the Renault, which captured Class A. The cars which had perfect scores were: Three Ramblers, two Chalmers-Detroit, two Buicks, Maxwell, Knox, Renault, American,. Stoddard-Dayton, Franklin, Corbin, Inter-State. The Inter-State has been protested.

A distance of 45 miles was provided for the first lap, passing through New Britain, Meriden, over Southington Mountain, Plainfield and Farmington. By the time that the last-mentioned city was reached the cars had strung out into a line and continued throughout the day, only once in a while getting bunched, for the rules were such that the contestants had to keep pretty well to each individual schedule. Southington Mountain was expected to furnish the first excitement of the day, but it was easy, for the road had been improved, and, in fact, the only poor road of the distance was at the entrance to Farmington, where the ooze was deep. All checked in and were sent away on a run of 57 miles, this time to the northeast, through Manchester, Rockville, West Stafford, Windsor Locks and Windsor. Macadam, sand and clay roads were met with in order and then varied after the first few miles were covered with the

Dennison's Knox, Mertens' Columbia, Goss' Corbin (Perfect) and Reid's Columbia.

mud giving the excitement, for the constant rain had no effect upon the sand. Hartford was made a noon control with a stop for lunch and a chance to take account of stock. In the second control at Enfield the Hon. H. R. Coffin's Columbia, driven by Mertens, was penalized for stopping its motor when it ran out of gasoline and having to renew its supply away from the control. Bourque in a Knox and Lorimer in a Chalmers-Detroit each changed a tire apiece during the morning, but there was a noticeable absence of the autoists' bugbear during the day. Another car joined the party at the completion of the first round, a Jackson, driven by E. L. Lazarro, which should have started with the other contestants. The car was sent around the three remaining laps, but was given no standing, although it made a perfect run at that distance.

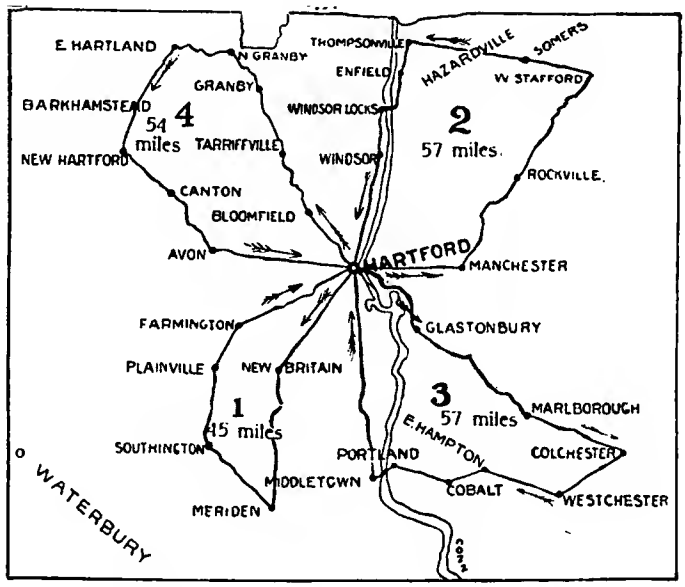
The real endurance run of the trip was that of the afternoon, through two laps, the first of which was to Glastonbury, Marlborough, Colchester, Portland and Middletown, a distance of another 57 miles. The rain had made the thirteen Colchester hills very slippery and the whole run was a harder one than those of the morning. As far as Glastonbury there was macadam, but after that sand and clay put forth their best efforts, seemingly to impede the tourists. The little Buick, driven by Hooker, had trouble with its timer and was forced to withdraw, and Dennison accidentally stalled his motor when his foot slipped from the accelcrator pedal, costing him one point. Shortly thereafter the Corbin, driven by Goss, took a notion to slide around inasmuch as there were no chains upon its tires, and after twice considering a ditching was brought up straight. Lorimer lost a point by stalling the motor of his Chalmers-Detroit and Miner's Pierce had ignition trouble which caused a halt and the loss of the clean score. The Mitchell, driven by Smith, had to make a stop for an adjustment to its oiling system and was accordingly penalized. Currier was another to stall his motor, a Columbia, showing that the road conditions bothered even the best of operators by the number which lost control for a moment. A detour was necessary at Rocky Hill, where a new State highway is being built, and the dirt road was used, but it caused no material inconvenience.

"Last, but not least," was the characterization of the fourth lap, one of 54 miles length, taking in the towns of Bloomfield, Tariffville, Granby, New Hartford and Talcott Mountain. The beautiful scenes along the route seemed to be a mockery when looked upon as compared to the road, for after the macadam at Bloomfield was left the cars dropped to the hubs in soft mire. The town authorities had made this worse by recently paring off the edges and throwing the loose turf into the center. The result was that the first car through plowed two deep furrows which every one had to follow, and the tracks grew still deeper until the axles began to level them off. Both men and machines took on a coating of mud, but all pulled through safely in spite of an up-grade a mile and a half long. There was a repetition or troubles, the same ones which were delayed on the third lap, because of deranged ignition or lubricating systems, having to stop on the fourth. Talcott Mountain was a feature of the last part of the day, for the fog was so thick that it was impossible to see more than 100 feet ahead, both on the ascent and then on the coast down into the Connecticut Valley. Reid's Columbia broke an oil valve on the base of his crank case, necessitating a

Rankin's Chalmers Checking.

Harry Hart in His Perfect Score American.

Pierce-Arrow Checking In.



Map Showing Course that the Run Covered.

stop, and the Maxwell Junior, which was doing wonderful work, was made late by tire trouble occurring in the dark. Hart in the American and Tuttle in the Stoddard-Dayton were also delayed by having to change tires, but time was allowed for this as long as the motor was kept running. Dean Rankin in the Chalmers-Detroit led the bunch over the mountain and down into the valley and then over Avon Mountain beyond. MacDonald smashed the spokes of a wheel on his Maxwell, but finished with a perfect score, and MacCormick's Pierce was 30 seconds late at the finish, thereby penalized one point, giving the Renault the only perfect score in Class A for cars costing over $3,751. Only one car failed to finish by evening.

With 15 clean scores before them the contest committee was in a quandry and it is probable that each of this number will receive a trophy. The scores of the Inter-State, Coffin's Columbia, and for a time that of MacCormick's Pierce were in doubt. The officials of the contest were given great credit for the manner in which it was conducted and the cars and drivers for having made such a hard trip so successfully. The officials were: Referee, A. L. Riker, Bridgeport, Conn.; timer, Albert M. Kohn; assistant timers, C. D. Alton, Jr., E. J. Manning, C. E. Whitney, J. H. Freeman, E. S. Edwards, G. E. Kohn; starter, W. C. Russell; superintendent of observers, A. G. Hinkley; superintendent of checkers, A. E. Woodford; checkers, E. A. Atkins, M. T. Russell, R. F. Gibbs, W. H. McLaughlin, W. B. Carroll and L. D. Hart. The following is the official summary:

CLASS A—CARS LISTING AT $3,751 and UPWARDS.

No.	Car.	H.P.	Driver.	Penalty.	
26.	Renault	30	C. E. Sykes	0	
27.	Pierce	30	R. H. MacCormick	1	Late at Hartford, 1 min.
28.	Pierce	45	S. A. Milner	34	Ignition troubles, 3d and 4th laps.

CLASS B—CARS LISTING AT $2,451 TO $3,750.

15.	Knox	38	Wm. Bourgue	0	
16.	American	50	H. A. Hart	0	
18.	Stoddard-Dayton	45	Harry Tuttle	0	
19.	Franklin "Six"	42	John Burns	0	
21.	Chalmers-Detroit	40	Dean Rankin	0	
24.	Corbin	30	Stanley Goss	0	
25.	Rambler	45	S. E. Campbell	0	
13.	Corbin	30	P. Corbin, Jr.	1	Stalled motor.
14.	Knox	38	A. Dennison	1	Stalled motor.
20.	Chalmers-Detroit	40	L. B. Lorimer	2	Stalled motor.
22.	Columbia	29	H. Currier	2	Stalled motor.
17.	Columbia	29	G. Mertens		Ran out of gasoline.
23.	Columbia	29	F. T. Reld		Broken oil pipe, 4th lap; withdrew.

CLASS C—CARS LISTING AT $1,751 TO $2,450.

10.	Rambler	34	E. W. Willlams	0	
11.	Rambler	34	J. E. Brennan	0	
12.	Buick	24	D. C. Lull	0	

CLASS D—CARS LISTING AT $1,000 TO $1,750.

5.	Buick	22	Bob Miner	0	
6.	Maxwell	28	J. Macdonald	0	
7.	Chalmers-Detroit	30	F. F. Cameron	0	
9.	Inter-State	35	F. L. Mills	0	
8.	Mitchell	30	B. F. Smith	40	Oil troubles. Took supplies away from controls.
4.	Jackson	30	E. L. Lazarro		Ran last three laps. No score given.

CLASS E—CARS LISTING AT $999 AND UNDER.

3.	Maxwell	10	C. E. Goldthwaite.	10	Arrived late at control.
1.	Buick	18	D. C. Hooker		Timer trouble in 3d lap; withdrawn.

BALTIMORE NOW WANTS MORE CONTESTS.

BALTIMORE, May 23—So pleased are the members of the Automobile Club of Maryland and the dealers with the recent sealed bonnet contest and endurance run that there is talk of holding a three days' endurance run and possibly a 24-hour race within the next month. A private contest is being talked of between the 28-horsepower Franklin and the 40-horsepower Studebaker, both of which finished with perfect scores in the club run. A substantial side bet may be made and the route spoken of is from Baltimore to Pittsburg and return. The Winton "48" and the Packard "30" which ended on even terms, each with a penalization of two points, are likely to get together in consequence of the rivalry that has cropped up since the contest. Another possibility involves the Gaeth and the Stoddard-Dayton.

Mill's Inter-State. Committee of the Hartford Automobile Club. McDonald's Maxwell.

W. T. Fenn, president; Arthur G. Hinkley, secretary; Thomas C. Russell, vice-president; W. C. Russell, C. H. Gillette, W. F. Plimpton, A. M. Kohn, A. D. Altan, and E. S. Edwards, contest committee.

Automobile Gasoline and Other Available Fuel

Part VII

By Thos. J. Fay

CALCULATIONS for compression rarcly accord with the actual compression in practice, due in a large measure to a mass of variables that cannot well be reduced to definite values. In the first place, it is very difficult to fix upon the initial pressure, p, which would be 14.7 (nearly) pounds per square inch, were the mixture to enter the cylinders without the aid of a vacuum. Suction is a necessity under the conditions that must obtain if carbureters are used of the class in which a float is present to regulate the flow of gasoline, or if any other method is employed involving piston displacement in the process of inspirating the mixture.

The absolute compression in pounds per square inch will be more or less depending upon the initial pressure, as well as upon the clearance volume in per cent. The curve, Fig. 34, shows the relation between clearance volume in per cent. and absolute pressure in pounds per square inch, taking the exponent "N" as equal to 1.3, in which there is a good chance for error, due to the difficulty involved in calculating for this value.

Exponent "N" Valuable in the Process of Determining Compression—The numerical value of the exponent "N" has been variously stated by the several authorities between 1.20 and 1.40, which difference is enough to assure that the results of calculation will be of small avail in practice. In any case the value of the exponent "N" will depend upon the speed of a motor and as a result it is only possible to calculate for clearance space on a basis, taking into account some one speed. What the clearance space ought to be then is a subject that will remain in the land of speculation to a vast extent, although it will be possible to approximate the same at some one speed of a motor. To find the actual clearance of a finished motor the method long ago adopted by marine engineers will be the most exact, in which the whole space is filled with water and the weight of water required is then ascertained. The water is then spilled out down to the level in the cylinder representing the top of the stroke and the weight of water in the clearance space is then compared with the weight of water left in the cylinder, which latter amount represents the cubical volume due to the sweep of the piston.

In designing cylinders, if they are not too irregular it is possible to calculate the respective volumes with a fair amount of accuracy, but all such calculations should be checked by the water displacement method before the calculations are accepted as final. This will, of course, put a nick in the store of conceit of the average designer, but it is better to do so than to have a large number of motors on the market in which quality is conspicuous for its absence. With a view to showing something of the ills that will follow errors in calculating clearance it is but necessary to assume a case. If preignition is eminent in a motor at an absolutc compression of, say, 100 pounds per square inch, which is a matter depending, (a) upon the completeness of scavenging, (b) the quality of the gasoline, (c) temperature of the motor, (d) various design features of the motor. The curve, Fig. 34, shows that 100 pounds per square inch, absolute compression, will be the result when the clearance is about 20 per cent. of the total volume of a cylinder. Increasing the clearance by 5 per cent. will reduce the absolute compression to about 80 pounds per square inch. An error of 5 per cent. is not impossible in work of this character and if the design is to be with a very high compression, as in certain classes of motors, to run at a high speed, an error of less than 5 per cent. will lead to trouble in all probability.

Taking motors for touring service it is not uncommon to find that the clearance is even as much as 30 per cent. of the total volume and 25 per cent. is a very common figure. When the clearance is to be fixed in the cylinders of a motor it is necessary to consider the factors as follows:

(A) The bore of the cylinders because the leakage factor will change and the loss of charge due to valves and manifolds as well as ports will undergo alteration.

(B) Increasing speed demands a decrease in the clearance space for the reason that the amount of mixture that will enter reduces in weight as the speed increases hence the compression falls off and the results are not so good. Part of this need will be due to ignition trouble in that the rate of flame propagation will be retarded; brought about, to be sure, by a reduction in compression as speed increases.

(C) If the cooling is direct, as in air-cooled motors, the heat transfer is at a higher level and the weight of fuel (mixture) will be reduced due to rarefaction of the mixture so that the clearance should be decreased to compensate for the loss of weight. On the other hand, the heat being higher, the result is that the gas expands more than enough to offset the difference in weight of fuel so that the net situation represents the equivalent to an increase in the clearance space in such motors. In air-cooled work it is not impossible to consider a clearance space of 35 per cent.

(D) In very slow-speed motors, especially for motor boats and in stationary motors, the clearance space should be higher, even 40 per cent. In this class of work the question of ignition does not influence the situation at all, in that there is ample time in which to ignite the charge, and the pistons can be so long with such a number of rings

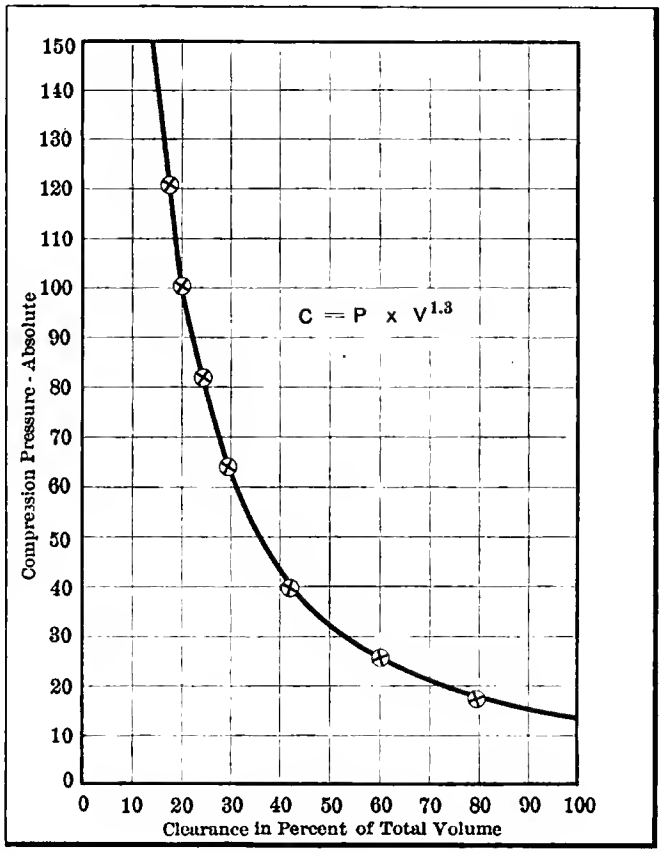


Fig. 34—Curve showing the clearance space for different values of compression when the exponent "N" equals 1.3.

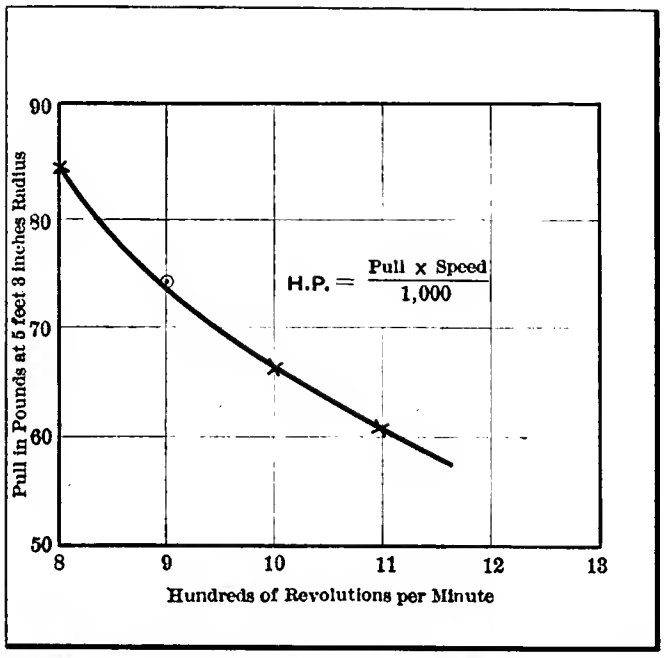

Fig. 35—Curve of torque of a flexible motor used in touring cars in which the speed is relatively low.

that leakage will not be a serious factor; moreover, there will be little or no loss in the ports, manifolds, etc.

This question of clearance space is not to be reduced to a rule that can be applied equally to all makes and sizes of motors and were it possible a means for adjusting the clearance for different speeds as well as for the several other conditions would be an advantage. True were it possible to adjust the clearance it would not be so necessary to adjust the spark under different conditions of speed. Indeed it might be quite possible to dispense with the spark changes were it easy to adjust the clearance instead, and for changing speed.

The fuel problem from all appearances is present in this question of clearance to a vast extent, and if it is true that the best results would follow were it possible to adjust the clearance as the speed changes it is equal to saying that motors have to be designed, taking into account the speed at which the designer intends to realize the most power coupled with such other details of design as will afford the maximum of flexibility.

That flexibility is not present in all motors is too well known to require proof; moreover, this question of flexibility is coupled with the compression more than is generally well understood. Take, for illustration, the larger sizes of racing motors; they are the worst kind of performers at low speeds. Why? The clearance space is much restricted, due to a desire to afford the best results from the ignition point of view at the higher speeds. The torque curve as shown in Fig. 28, plainly illustrates an increasing torque with decreasing speed, as against an increasing power with increasing speed. This is quite the reverse to what one would expect as a general proposition, although it is true that the power of a motor is maximum when speed multiplied by torque is a maximum rather than when speed or torque is the highest.

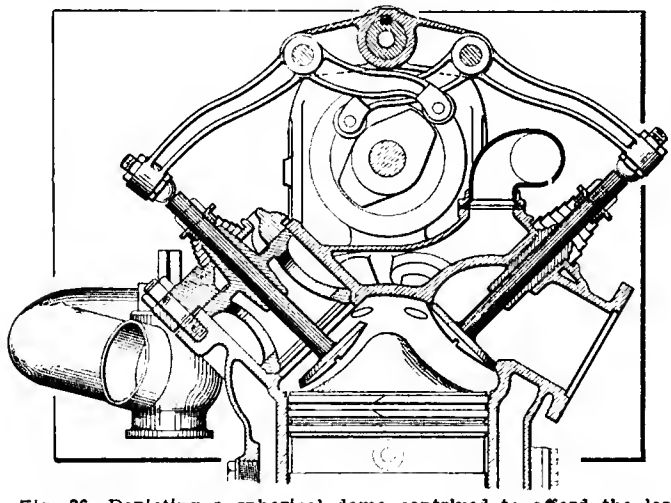

Fig. 36—Depicting a spherical dome contrived to afford the least surface and the quickest means of disposing of the exhaust.

The exponent "N" should be as high as possible, all other things constant, for, as will be shown if a problem is considered, when the exponent "N" is low relatively, the density of the charge will fall off to correspond. In ordinary work it is very likely that the absolute pressure will be as low as 13 pounds per square inch (or even lower) during the suction stroke of the motor with the chance that it will not hold to this value during the whole stroke. In some cases the absolute pressure has been found to be higher, and even 14 pounds might be considered as having obtained in some cases with fine carbureters.

Increasing speed should reduce the absolute pressure during the suction stroke, and if this is true, it is then reasonable to assume that the weight efficiency of a motor will increase as the absolute pressure decreases within certain limits, which is so when the power of a motor increases as the speed increases up to a certain point, during which period the absolute pressure is on the decrease. For a given speed then the absolute pressure should hold to a maximum during the suction stroke, although it is true that the power will be higher if the speed is increased provided the torque does not fall off at a rate greater than the rate of increase of speed as it generally does.

Conventional Formula Involving the Exponent "N"—The exponent "N" was taken as 1.30, which is a good average value in motors if the absolute pressure is 13 pounds per square inch on the suction stroke. If the absolute pressure increases to, say, 14 pounds per square inch on the suction stroke the exponent "N" would fall off and the average value of the same might well be placed at 1.25 or slightly above. For the formula the following will hold:

Let

V_1 = total volume of a cylinder, which includes piston displacement as well as clearance volume,

V_2 = clearance volume of the cylinder, which is the total volume less piston displacement,

p_1 = absolute pressure corresponding to V_1,

p_2 = absolute pressure corresponding to V_2,

then

$pV^n = c$ = clearance in per cent. of whole volume.

and

$$p_1 V_1 = p_2 V_2,$$

therefore

$$\frac{p_1}{p_2} = \left(\frac{V_2}{V_1}\right)$$

and

$$n = \frac{\log p_1 - \log p_2}{\log V_2 - \log V_1}$$

What Practice Would Seem to Indicate—If a motor is to be used for racing, taking into account such conditions as will be indicated by high speed, in which no notice will here be taken of what is generally designated as flexibility, the compression should be very high at low speeds in order that it will be enough at high speeds to well serve the purpose. If, on the other hand, the motor is to do general service, in which flexibility is of the greatest importance, it is then that the compression should be low enough to assure a fair measure of flexibility, which, to be sure, will thwart the performance at high speed. If the motor will not run at a high speed the weight efficiency will not be a minimum and the power (on the higher level of speed) will be that as indicated by a receding torque curve, as shown in Fig. 35. That this is a good torque characteristic for motors that are to serve under ordinary conditions would seem to be true primarily because the flexibility question is in better

shape and the chances of cylinder trouble due to high strains will be reduced. In this case the power was a maximum at about 800 revolutions per minute of the motor crankshaft, which is very different from the performance of the racing motor as portrayed in the curve, Fig. 28, in which case the maximum power was at about 1,800 revolutions per minute of the crankshaft.

Power Corresponding to Torque—In view of the length of the leverarm of the Prony brake, as used in the test of the motor, the curve of which is given in Fig. 35, the formula is very readily determined in the manner as given in the curve, an example of which will be as follows:

When

$H.P.$ = actual horsepower of the motor

P = pull in pounds at 5 feet 3 inches radius = 85

S = speed of crankshaft in revolutions per minute = 800

then

$$H.P. = \frac{85 \times 800}{1{,}000} = 68 \text{ horsepower.}$$

HORSEPOWER AT DIFFERENT SPEEDS AND TORQUE VALUE

Speed.	Torque.	Speed x Torque.	Horsepower.
800	85.0	68,000	68.00
900	74.2	66,780	66.78
1,000	66.7	66,700	66.7
1,100	60.61	66,671	66.67
1,200	52.5	63,000	63.00

As the curve shows, the power is almost constant for all speeds between 800 and the maximum speed above given, and in the test it was found that the power fell away in inverse proportion as the speed decreases below 800 revolutions per minute and the power decreased as speed increased above 1,200 revolutions per minute. On the face of it there was no use in gearing this motor to run at speeds above 800 revolutions per minute and that the motor would last longer in service at 800 revolutions than it would at 1,200 revolutions is too plain to require any proof at all. The natural inference is that this motor was not well designed; this inference will be sustained by the facts provided a racing motor is in the mind's eye. Obviously this motor was designed with a relatively low compression and with valves so small that beyond a certain point the speed would not increase even with a proper fuel adjustment and with the spark timed for the best results as well as running free.

That a motor such as this would be capable of doing good work without having to place a governor to limit the speed as the load falls off (as it does when the clutch is withdrawn) is one of the points in its favor, and as to the weight efficiency, it was high enough in this case to class the motor as satisfactory on the ground that the weight efficiency was on a basis of 13.3 pounds per horsepower, which is a fair average figure, although it is true that racing motors deliver on a basis of about 10 pounds per horsepower, or even better.

Weight Efficiency Is a Matter of Design—If a motor is to last for a long time in the hands of men of no great skill it follows that the design must take all the conditions into account, and when the fuel, which is the real source of power, is to be used on a highly efficient basis, then the weight efficiency must be high and the life of the motor will be reduced accordingly. This is not a question that will involve the actual transfer of energy from the fuel, for the reason that this transfer can easily be the same in the motors of different weights under fair conditions. In this case then it is a question of the mechanical efficiency of transfer, and as a matter of fact, high weight efficiency may mean low mechanical efficiency as well as an increase in the factor of depreciation.

Designers have their choice between high weight efficiency, with its attending shortened life and lower mechanical efficiency, as against a lowered weight efficiency, increased life and, of necessity, increased weight, which may affect the final results to the extent of reducing the ultimate fuel efficiency. In the final sum-up of fuel efficiency it is a question of "ton-miles" per gallon of fuel or per pound of the same. If the motor is heavy and the car is on the same basis, it is a moral certainty that the load that the car will carry will be reduced accordingly. On the other hand, if the motor is light and the car is along the same lines, it is more than likely that the safe load on the car will be limited. In any design then, taking into account the fuel, with the idea of realizing the greatest result per pound of the same, some standard must be established such as will represent all the conditions that go to form good success.

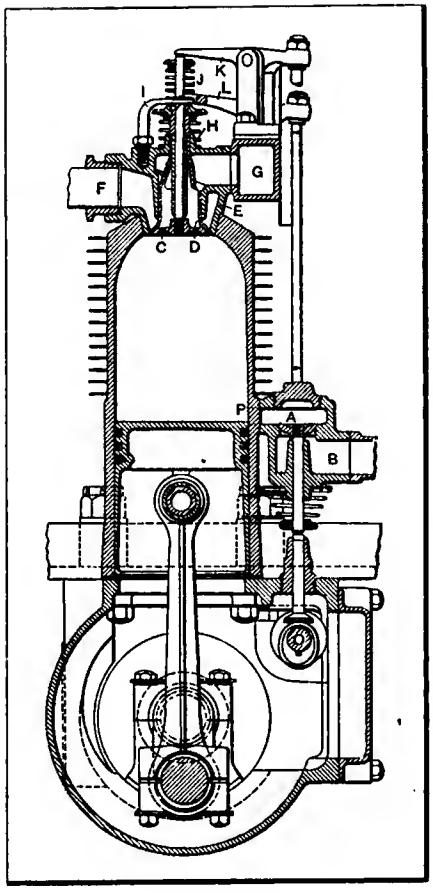

Fig. 37—Franklin air-cooled motor, presenting a spherical dome and concentric valves, as well as an auxiliary valve for the quick elimination of exhaust products.

Strike a Balance Involving a Happy Medium—In all probability the conservative course lies in a design that will embody enough weight to do the work for a long time, which time should be related to the first cost of the car as well as the actual service that it will render so that the "burden" a car will safely sustain under is an important detail to be taken into account. The actual

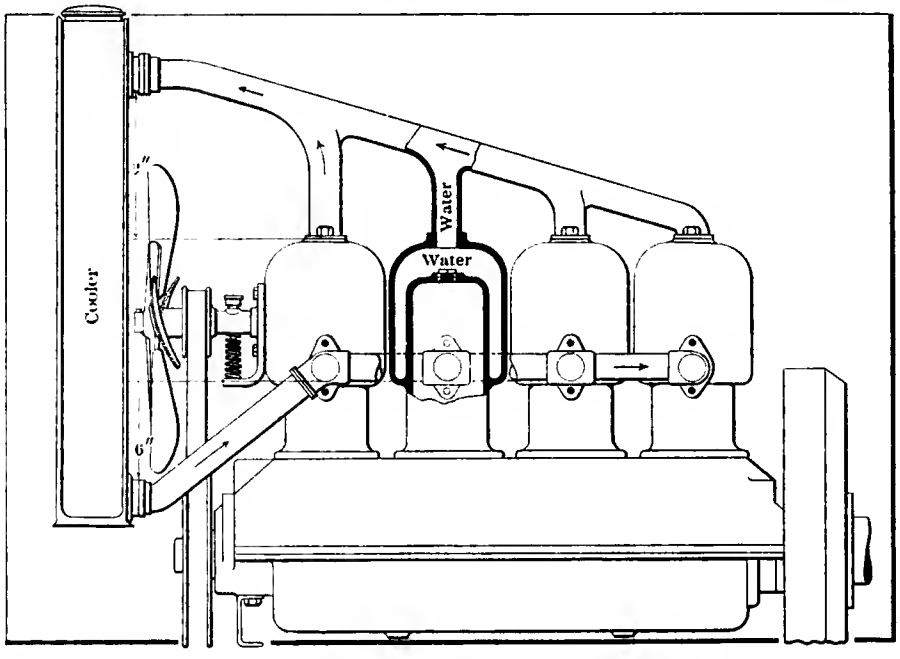

Fig. 38—Thermo-syphon system in which the boiling jacket-water influences the thermal efficiency of the motor.

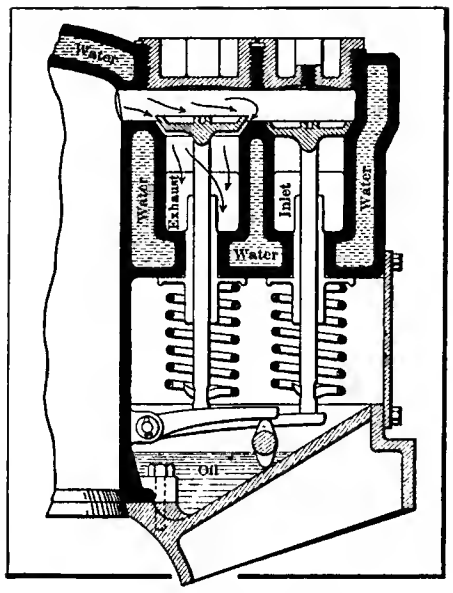

Fig. 39—Valves in lateral tandem and spark-plug over the intake, adjacent to the heated exhaust valve.

fuel efficiency of automobiles will best be known by performance under ordinary road conditions rather than as the result of special economy trials, yet even so special efforts lead to knowledge of the requirements and designers are enabled to make improvements when they know what to improve.

Some Details That Influence the Situation—Mixture alone, or even the best mixture and the most suitable compression will fall short of the requirements in the absence of other important considerations. Take, for illustration, the shape of the combustion chamber; there is no denying the contention that the results can be influenced thereby. The least surface for a given volume will be due to a spherical contour. That the surface should be the least possible is generally conceded on the ground that the losses to the water-jacket will then be reduced to the lowest possible point.

A spherical head demands the location of the valves in the head of the motor and this is probably the best reason why some very efficient racing cars are provided with motors in which the valves are in the head, one of which is illustrated in Fig. 36. In this case the piston head is probably not in accord with the rest of the design, but this is a detail outside of the main question, for the reason that the piston is not water-jacketed, and the losses to the water-jacket are not therefore involved.

The same idea is embodied in Fig. 37 of the Franklin (air-cooled) motor, only that in the Franklin the piston is in accord with the main theory and the valves are so designed that the combustion chamber is almost a true sphere. The fact that the Franklin is air-cooled makes no inroad on the accuracy of the main conclusion for the very good reason that all motors are air-cooled (some of which, direct, as in the Franklin, and the rest are indirect, as in the water-cooled examples). The losses to the cooling medium must be taken into account in any case and, as before stated, if the surface is small the amount of heat that can pass off will be reduced in consequence.

In the Franklin motor it will be observed that the valves are in a concentric nest, and referring to the illustration, Fig. 37, *A* represents an auxiliary valve which is a great aid in scavenging the motor and the exhaust leaves through the port *P*, passing off to the pipe *B* and thence to the muffler. The main exhaust valve *C* is provided with a seat by the intake valve *D* and the exhaust passes off to the manifold *G* while the intake is shown at *F*. The exhaust valve is mechanically operated by the arm *K* and the spring *J*, while the inlet valve is mechanically operated by the arm *L* and the spring *H*. The bent arm *I* serves to resist the pressure of the spring *J*. That the fine performance of the Franklin is largely due to the valves provided is assured, and the auxiliary valve is regarded as of the greatest utility in air-cooled work. The idea, while it takes into account the question of scavenging, is most important from the point of view of disposing of the heat in the shortest possible time.

Differences Due to Methods of Water Cooling—It is common to claim that the water as it is led to the water-jacket of a motor should be entered at the hottest part in order to enable the water to absorb the greatest amount of heat of which it is cable in the short time allowed. This idea is a good one up to a certain point, although it is contrary to the idea of maximum thermal efficiency because the greater the difference in heat the more will be the loss to the water-jacket. In the thermo-syphon systems the water is handled in the manner as shown in Fig. 38, and as will be observed, the boiling water is allowed to raise directly above the dome of the combustion chamber thence away to the cooler. That the water does boil and that steam does form above the combustion chamber is a matter that will be easy to prove in many cases at any rate, and that the thermal efficiency is increased thereby is a moral certainty. The thermo-syphon system is in the nature of a middle practice between the direct and the indirect methods of cooling, and since both the direct and the indirect methods work in practice there is nothing to prevent the thermo-syphon system from serving well the purpose rather with the expectation that the result will be as a happy medium between the two.

From the fuel point of view these matters have to be taken into account on the ground that it is the fuel problem that dictates the cooling rather than the mechanical problem. Lubricating oil is now to be had of a character suitable for use under the most severe conditions, from the temperature point of view, so that, as before stated, it is the fuel question that influences the major effort in the cooling problem.

Location of Spark Plugs Must Be Considered—There are two sides to this question, in that the mixture must be suitable for the purpose as well as it is true that the ignition system must be of the greatest possible efficiency. For the present it is the mixture phase of the subject that will be treated. Since the mixture is not equally homogeneous in all parts of the combustion chamber, leastwise in motors in general, it is a fair inference that the spark plug should be located in the zone that will afford the greatest uniformity, for then the results will be the most satisfactory. Fig. 39 shows a design of cylinder in which the inlet valve is placed outside of the exhaust valve on the same side of the cylinder, and as will be readily understood, the mixture comes in and passes over the heated exhaust valve so that while the exhaust valve is thereby cooled it is also true that the mixture is heated up at that point and it becomes very inflammable as a result.

In cylinders of this design it was found that the spark plugs worked very much better over the inlet valve than they would when placed over the exhaust valves. This was found to be true after repeated trials with the spark plug in the respective places at different trials and the only way to account for the difference is to assume that a more uniform mixture is to be had over the inlet valve with the possibility that the close proximity of the heated exhaust valve has an influence for good. All of these questions of the location of the spark plug take into account the question of scavenging, for were the cylinders completely emptied of the exhaust products, it is highly improbable that the location of the spark plug would be a matter of such great moment.

There is one other phase of this question, although it is but a variation of what has already been stated. If the carbureter is an imperfect device and if liquid gasoline enters the cylinders of motors the spark plug should not be located in a highly heated zone, for then the coking process will take place in contact with the nodes of the spark plug with the result that the plugs will soot up. When the spark plug is in a pocket to one side of the combustion chamber it is probable that the coking process is sufficiently isolated from the spark plug to enable the same to perform its functions without sooting up.

Since water is one of the products of combustion and in view of the short-circuiting effect of a drop of water on the nodes of the spark plug, it is also desirable to locate the same out of the zone of direct and intense combustion rather with the hope that water will not form on the nodes. This question of water interfering with ignition will stand some more investigation.

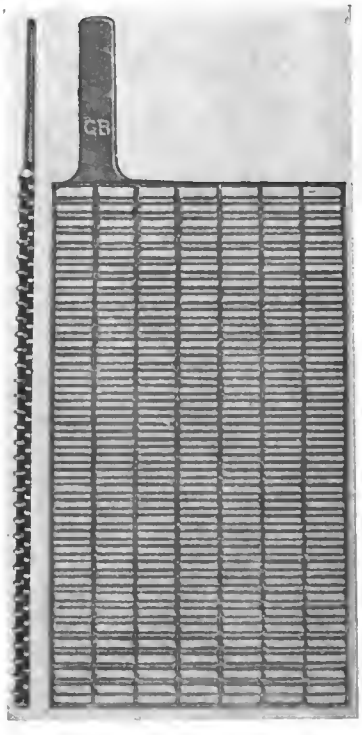
(To be continued.)

Some Further Ignition Hints

By Morris A. Hall

A QUESTION often asked relative to the popular use of storage batteries for ignition purposes is, is this popularity deserved or not? In their favor it must be said that they do the work and do it well; even enemies will admit that. But it is a fact that the general automobiling public do not understand the action of a storage battery, and as a result those who shun its use are numerous. So, it will be an excellent idea to look into its action and see wherein it is simple and where, if at all, it is complicated.

First of all, it will be necessary to say that in what follows much is described which pertains to storage batteries for the propulsion of cars and other heavy work, rather than for the lighter simpler work of gasoline ignition. The excuse is offered, however, that in principle and in action all storage cells or accumulators are alike, so that a description of one is a description of all of them.



Staggered Positive Battery Plate.

Primarily, the action of generating a current in a storage cell is a chemical one, so any explanation of the internal action must go into the chemistry somewhat. Ordinarily, the lead battery is used, in which lead in two different forms is used for the two electrodes. These electrodes are placed in dilute sulphuric acid which attacks the lead, with the result that a lead sulphate is formed and the acid reduced to water or atoms of free hydrogen.

The water used should be pure distilled water and should not be poured into the acid. The proper method of procedure is to pour the acid into the water. The influence of a small addition of acid to water is very small, practically negligible, while adding water to a body of concentrated acid, sets up a chemical action which is liable to be a violent one, the heat liberated by the action in this case being very great.

The Fundamental Battery Equations—This fundamental action is best expressed in the form of an equation, or more correctly, several equations, which represent correctly the action taking place in the battery. Thus we have:

$$\xleftarrow{\text{Charge}}$$

(a) $Pb\,O_2 + H_2\,SO_4 = Pb\,SO_4 + H_2O + O$

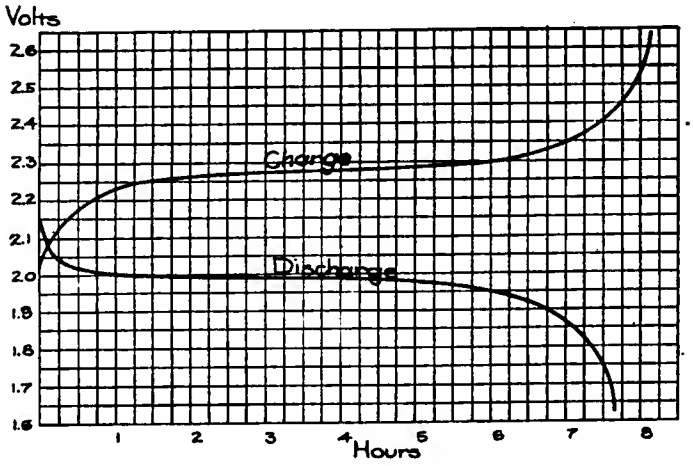
(b) $Pb + H_2\,SO_4 = Pb\,SO_4 + H_2$

(c) = (a) + (b) or

$$Pb\,O_2 + Pb + 2H_2\,SO_4 = 2Pb\,SO_4 + 2H_2\,O$$

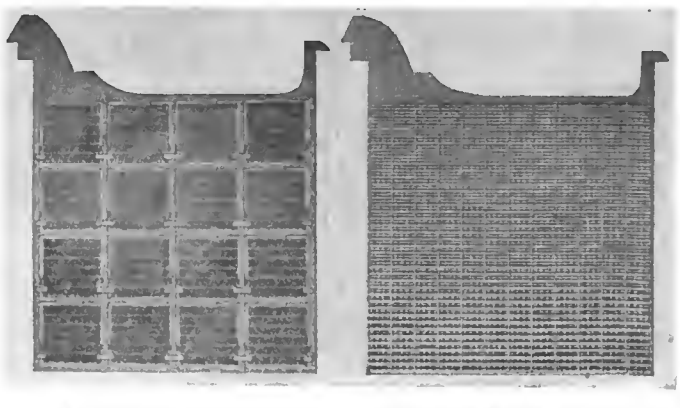
$$\xrightarrow{\text{Discharge}}$$

in which (a) is the reaction at the positive plate, (b) the action at the negative plate and (c) the combined effort or the fundamental equation of the lead storage battery. This equation shows that on charge, both electrodes start as lead sulphate, $Pb\,SO_4$, and combining with the dissociated gases of the water in the electrolyte, at the negative plate, turn into lead, and at the positive plate into lead peroxide, respectively. Also, the SO_4 is released which combines with the water in the electrolyte to form sulphuric acid, $H_2\,SO_4$. Reading from left to right for the discharge, as indicated by the lower arrow, it is seen that the action is the change of lead and lead peroxide, respectively, on the negative and positive plates, into lead sulphate, and the reduction of sulphuric acid into water.

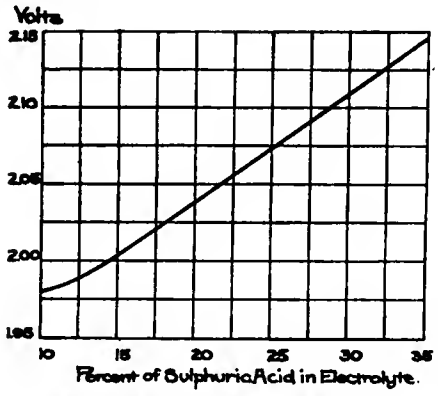


Typical Diagram of Charge and Discharge.

This, of course, represents only the initial and final reactions, as scientific men have never been able to prove or even agree upon the various intermediate reactions. Among the products said to be formed, each having somewhat of a following, are: Persulphuric acid, $H_2\,S_2\,O_8$; perplumbic acid, $H_2\,Pb_3\,O_7$; hydrated lead peroxide, $H_2\,Pb_2\,O_5$, and many others. Without going into this matter, which at best is beyond the scope of this paper, it will be sufficient to say that this action, although chemical, produces an electric current and it flows, when the two terminals of the positive and negative plates are connected by means of a substance, which is a conductor of electricity. These are usually copper wires, but the terminals of the battery itself are usually widc strips of lead.



A Comparison of Ordinary Positive and Negative Grids.



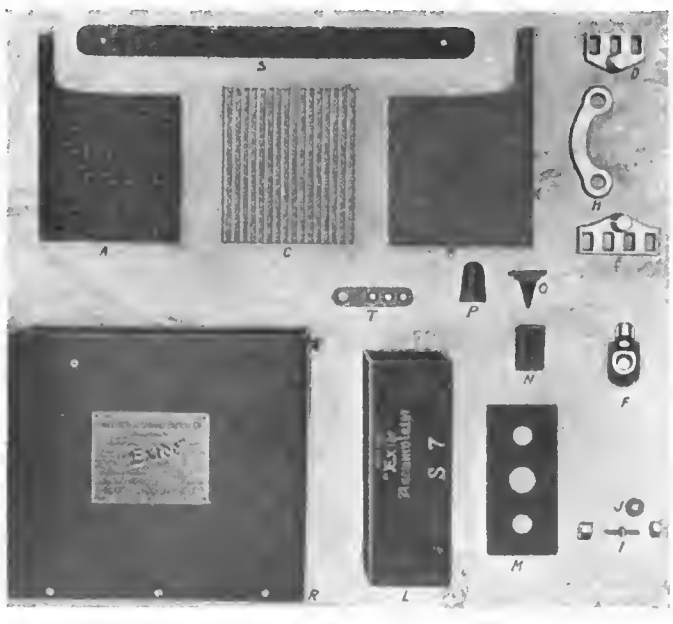
Adding Acid Increases Density.

There are three necessities in battery plates, which cause the varied use of substances differing so widely as those found on commercial examples. These three are: Strength, rigidity and high conductivity. Strangely enough, no one of the active materials now in use possesses a single one of the qualities enumerated. Lead, spongy lead and lead peroxide are in very general use and no one of them possesses any one of the requirements mentioned.

This means that battery plates must be made in two parts, the active material, which does the work and produces the current, and the rigid framework, called a grid, to which the material is added, and which possesses the required qualities. The rate of current flow at which the battery may be discharged depends upon the area of the surface on which the electrolyte acts. This area may be large or small, but as a high-flow rate is very desirable the area is made as large as possible. The active area is measured in square inches and is the product of the length times the breadth times two, because both sides are active. This is for one plate, and must be multiplied by the total number of positive plates.

Unit of Capacity Defined—The usual or standard unit for measuring capacity is the ampere hour, the product of the rate of discharge (previously spoken of as the rate of current flow) by the time which the battery takes to discharge at the standard rate 1.8 volts. Units of capacity vary with the rate of discharge, the unit being less at a rapid rate than at a slow rate, although the contrary might be thought to be more reasonable. The eight-hour rate is normal, that is to say, this is the usual time in which the battery will discharge its rated current without falling below the set figure of 1.8 volts. As an example, a battery rated at 80 ampere-hours will discharge 10 amperes continuously for eight hours without falling below 1.8 volts.

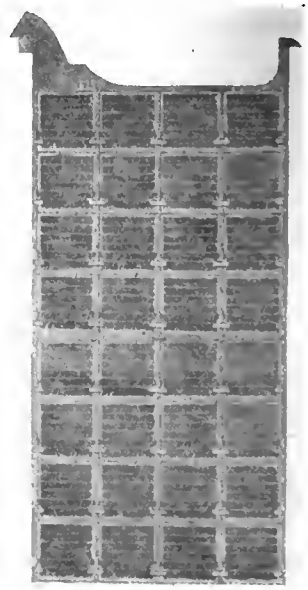
Electromotive Force, abbreviated E M F, is defined as the electric pressure or difference in potential between two points, in this case, the positive and negative electrodes, causing current to flow. Now the sulphion SO_4 is abstracted from the electrolyte on discharge as the fundamental equation shows. If this were carried to extremes, and all of the SO_4 taken, then only water would be left, and the E M F would be but 1.46 volts. But SO_4 is actually only taken from the acid where it is in contact with the plates. As it is removed the density is decreased, which causes circulation, thus allowing fresh acid to take the place of the exhausted. The chemical action is quickest in the minute pores of the plates, where the circulation is most difficult. When the cell is allowed to stand these minute areas are flooded with fresh electrolyte and the voltage will rise a very marked amount. The foregoing is the explanation of the recuperative power of a storage cell, which allows the voltage to rise after discharge has taken place, if the battery be allowed to stand on open circuit for a few minutes.



Complete Set of Parts of Sparking Battery Dissembled.

Success Requires Many Things—The principal requirements of a satisfactory storage battery are many and total at least seven. These are:

(1) The arrangement of the grid and actual material must be such that the current flows equally through all parts of the plate. This requires that the resistance be the same from any two points to the lug, which is obviously impossible theoretically, but in practice is approximated.



Sometimes the Grids are Made Long.

(2) The construction of the grid must be such as to allow of expansion and subsequent contraction under the heat of charging and discharging. As the source of most of storage battery trouble this has been given much thought without remedying the trouble. One could almost say that this requirement is impossible of attainment. The expansion on formation, or charging as it is called, is very great.

(3) Fastening of the active material to the grid is most important as is also the electrical contact at the lines of fastening. Usually both are good at first, but on subsequent expansion the electrical contact is lost first, resulting in the ultimate loss of any actual contact. When that happens the battery is useless.

(4) Construction of the grid should be such as to resist the corrosive action of the acid. While practically impossible, the material is so selected and proportioned as to last as long as the active material, so that in replacing the latter it is easy to also replace the former.

(5) Local action must be prevented, which is done by making the grid of such a material that no action is set up between the plate and the active material. In many cases sheet lead is used and serves well the purpose.

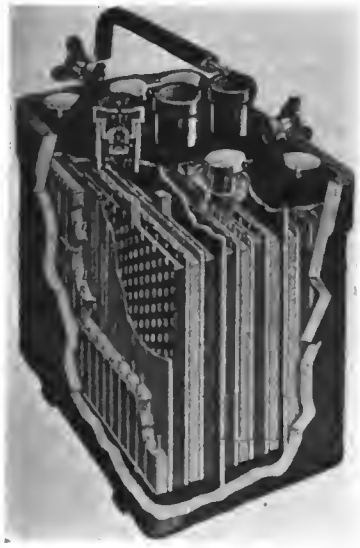
(6) Provision must be made for the circulation of the electrolyte, this being fully as important as any of the foregoing.

(7) Last but not least, the active material must be so disposed as to present the greatest possible surface to the acid.

As of interest and pertinent to the subject, a number of different grids are shown. The usual shape is nearly square, but in some exceptional cases it is desirable or necessary to have a long or narrow shape. With this, the depth of the acid assumes a more important place than in the case of the ordinary plate. As of equal concern to the novice, all of the parts of a storage cell, built primarily for sparking purposes, are shown, even to the hard rubber jar, and the wooden box which encloses the whole. Another illustration shows a different sparking battery assembled but with a corner cut out to display the manner in which the parts are correlated when ready for use.

To contrast with these, a full set of cells for car propulsion is shown, connected up ready to be put in place. These show little of the internal construction, but give a good idea of the size and space necessary for a vehicle's motive power.

Charging and Discharging Display Peculiarities—In the first diagram is shown the phenomenon of charging and discharging, represented graphically. From this it will be seen that the two operations are by no means the reverse of one another. On charge, beginning with two volts, the current rises rapidly in the first hour to 2.25 volts, from which the increase is more gradual during the ensuing time up to about the seventh hour. At this time the cell is nearly charged, and the voltage rises with great rapidity to 2.65, during which latter rise much care must be exercised else the battery will be overcharged with consequent damage.



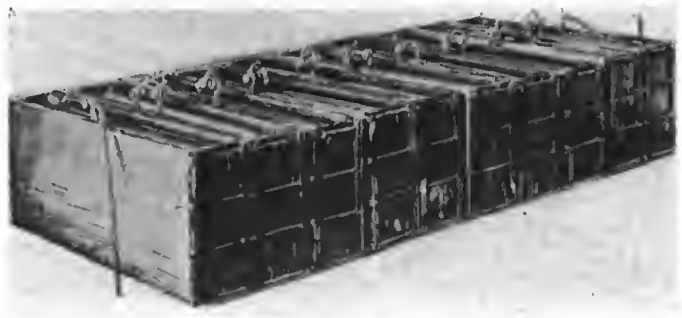
Battery Cut Open to Show Construction.

Upon discharge, an entirely different set of results are met. Commencing at a high voltage of 2.15 the drop within the first fifteen minutes is very noticeable. After this it is more gradual up to the end of the first hour, beyond which it assumes a very slow, gradual drop to the end of 5½ hours. At that time the drop becomes more pronounced, and beyond the seventh hour must again be carefully watched else the cell will be drained down below a healthy point, causing damage which cannot be repaired, at least not readily or without proper facilities.

Storage cells exhibit a number of peculiarities, some of which are very interesting. For instance, if a cell is fully charged and then allowed to stand for a long period without being used, when put into use and discharged the voltage does not begin with a decided drop as in the ordinary case, but on the contrary rises for nearly an hour and a half. Beyond this point, however, the drop is more sharp than in the ordinary case, at least for the middle period. At the end of the discharge the drop is much less rapid than in the case of a cell which has not been allowed to stand, fully charged, before using. This condition is shown in one of the curves, and persists through several alternations of charge and discharge, before resuming a normal condition, such that the voltage at the beginning of discharge is high, falling off rapidly during the first few minutes.

A second peculiarity is even more strange. When a cell is used and allowed to stand, it recuperates and, as spoken of above under the heading of electromotive force, the action is a sharply defined one. At any rate, a large amount of additional current may be obtained without damaging or destroying the cell. If now, the cell, in the first instance, be discharged very rapidly, allowed to stand, and used a second time, the recuperative current will be very large, so much so that the total of the first and second discharges will be far in excess of the summation of the two in the first or more ordinary case. In other words, by discharging at an initial high rate, a greater total amount of current may be obtained from the battery. This method of increasing the amount of current flow is to be deprecated, as a high flow rate usually warps the plate, causing subsequent current loss as brought out under requirement three.

Cell Which Has Stood for Some Time, Fully Charged, Has a Peculiar Discharge Curve.

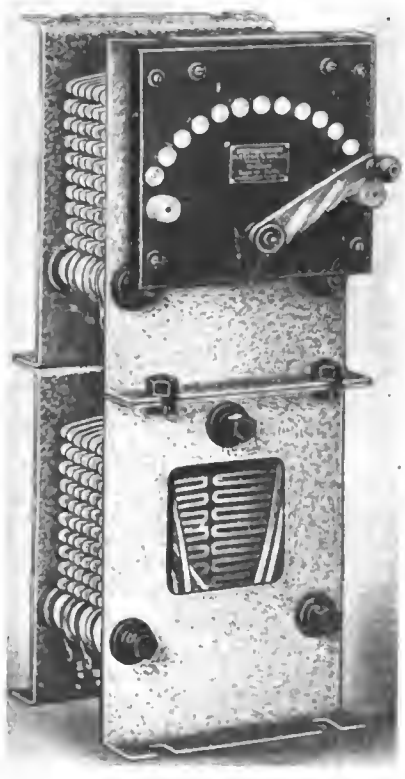


Electric Car's Power Plant Ready to Be Put in Place.

Current Varies with Electrolytic Density—It is a well-known fact among storage battery men that the voltage of any cell may be and is, influenced by the density or specific gravity of the acid solution, also, as a matter of fact, by the internal resistance and the temperature. Considering the two latter as fixed the output can be increased by an increase in the density of the electrolyte. This is done by adding a larger percentage of acid. The specific gravity of pure concentrated sulphuric acid is 1.850. As this is weakened by the addition of water, the density falls and the normal figure is about 1.250 for a fully charged cell, which decreases to about 1.150 on discharge. The curve shows how the addition of acid affects, favorably, the voltage.

There are a few general pointers which may be given to drivers who attend to their own storage batteries. The density of electrolyte, just mentioned, should be kept low, for this prevents sulphation. The temperature coefficient is negative, the resistance increasing with increased temperature, and decreasing with a drop in the thermometer. The electrolyte should be of acid made with sulphur and not from pyrites, as the latter is liable to contain injurious substances.

Mechanical Current Generators More Popular—While persons using storage batteries soon get into the habit of gauging the time of a charge, and planning forward to having it recharged at such a time as to keep the car out of commission the shortest possible length of time, the mere necessity for constant recharging has prejudiced many against it. Among these a form of mechanical generator is preferred for its ability to furnish current as long as the engine runs.



Storage Battery Charging Rheostat for Direct Current.

Compact Dynamometer Embodies Distinctive Principle*

By Prof. Wm. H. Kenerson

THE author has received from time to time many requests for a simple transmission dynamometer, and has himself often felt the need of one which would be more generally applicable than those now in use. These continued requests, together with the requirements of a definite problem whose solution demanded a rigid transmission dynamometer in the form of a coupling, led to the design and construction of the instrument described below. The accompanying illustrations show the construction of the dynamometer and its method of application and use. In Fig. 1 and Fig. 3 the corresponding parts of the dynamometer are given the same letters and are referred to in the body of the text.

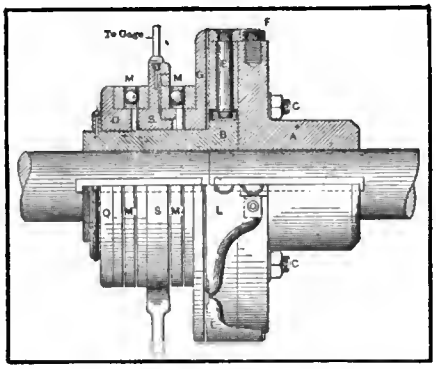


Fig. 1—Dynamometer shown in section.

The couplings *A* and *B*, each keyed to its respective shaft, are held together loosely by the stud bolts *C*. The holes in the flange *A* are larger than the studs *C*, so that these studs have no part in transmitting power from one shaft to the other. The power is transmitted from *A* to *B* through the agency of the latches *L*, four of which are arranged around the circumference of the flange *B*. These latches are mounted and are free to turn on the studs *E*. The two fingers of the latches engage the studs *F* on the flange *A*. On the ends of each latch are knife-edges parallel to the stud about which the latch turns. For either direction of rotation of the flange *A* the latches *L*, which are in effect double bell-crank levers, will exert a pressure on the disc *G*, tending to force it axially along the hub of the coupling *B*, and this pressure, it will be seen, is proportional to the torque.

Between the end-thrust ball, or roller, bearings *M M*, is held the stationary ring *S*, which is the weighing member. *O* is a thrust-collar screwed on the hub of *B*, and *P* is its check nut, which is ordinarily pinned to the hub when in position. The stationary member *S*, in the form of a ring surrounding the shaft, is prevented from rotating by fastening to some fixed object the attached arm. In this ring is an annular cavity covered by a thin diaphragm of sheet copper, *D*, against which the ball-race of a thrust-bearing presses. The edge of this ball-race is slightly chamfered to allow some motion to the diaphragm. The cavity is filled with a fluid, such as oil, and connected by means of a tube to a gage. The oil pressure measured by the gage is proportional to the pressure between the thrust-bearings, which in turn is proportional to the torque.

The instrument may be calibrated in the torsion-testing machine or by means of a sensitive friction brake. Fig. 4 is an actual calibration curve for a small instrument, obtained by hanging standard weights at proper distances from the shaft on a horizontal lever attached to the shaft, and reading the pressures indicated by the gage for the various torques shown in the diagram. For ordinary purposes, however, it is not necessary to calibrate the instrument by actual trial, since computations of the oil pressures for the various torques from the lengths of the lever-arms and diaphragm area check very closely.

It will be seen that the weighing means is similar to that employed in the Emery testing-machine, which is recognized as being extremely accurate. It will be possible to employ the Emery flexible steel knife-edges on the levers if desired, but this has been found in practice an unnecessary refinement.

The construction makes the coupling as nearly rigid as materials will permit, the movement of the diaphragm being extremely small. The only flow of oil through the copper connecting-pipe is that sufficient to alter the shape of the Bourbon tube, if that be the form of gage employed. As soon as the normal position of the gage is reached this flow ceases, hence there can be no fluid friction. It is possible, therefore, to use as long and as small a tube as desired without introducing error. Where the gage is placed at a distance above or below the level of the coupling correction should, of course, be made for the difference in static head.

Other means than the gage shown may be employed to measure the fluid pressure. Where extreme accuracy is desired it will be well to employ the weighing-device used with the Emery testing machine. The manograph has been used in this connection to measure variations in torque too rapid for indication by the ordinary gage. For example, the variations in torque in a single revolution of the shaft of a three-cylinder gasoline engine have been recorded with its aid.

Where the rate of rotation of the shaft is variable and it is desired to indicate the horsepower direct, the combination of gage and tachometer shown in Fig. 5 is employed. The hydraulic gage is connected to the coupling described, its pointer therefore indicating torque. The pointer of the tachometer shows the number of revolutions per minute. Being a function of the revolutions per minute and the torque, the horsepower will be indicated by the intersection of the two pointers and suitable curves on the dial as shown. Arrangements for recording or integrating the work done may also be attached to the coupling in any ordinary manner, or a gage may be used.

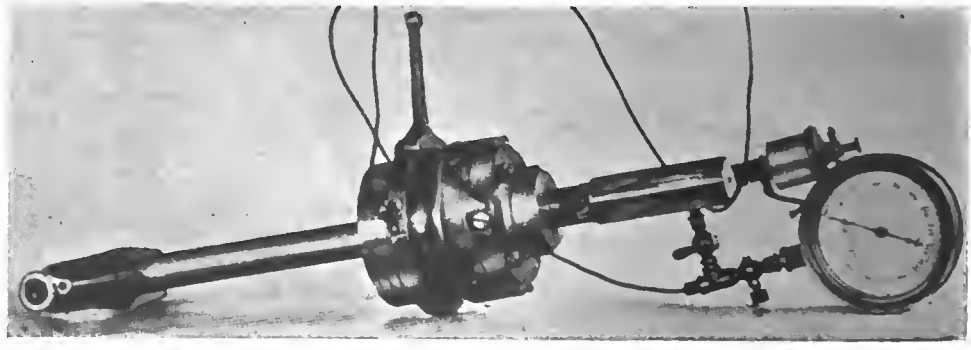

Fig. 2—Transmission Dynamometer in automobile propeller shaft, 30-horsepower at 500 R. P. M.; weight, 25 pounds.

*Presented at the Washington Meeting (May, 1909) of the American Society of Mechanical Engineers.

A summary of some of the more important characteristics of the instrument follows:

a The instrument is compact. The example shown in Fig. 2 and Fig. 3, which is designed to transmit 30 horsepower at 500 r.p.m., is about 5 3-8 inch in diameter and weighs about 25 pounds.

b It is as rigid as an ordinary flange coupling.

c It may be made in the form of a coupling, and will then occupy about the same space as the usual flange coupling, or it may be made in the form of a quill on which a pulley is mounted, or any other suitable form. This form may be made in halves for application to a continuous shaft.

d It will indicate for either direction of rotation of the shaft.

e The torque may be read and recorded or the work integrated at a considerable distance from the coupling.

f The readings do not require correction for different speeds of rotation. All parts containing oil are stationary, hence are unaffected by variation in speed. Other parts are likewise unaffected by the action of centrifugal force.

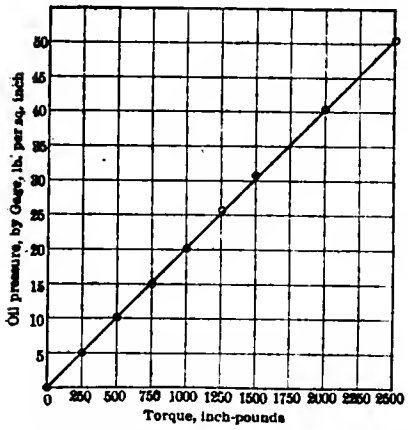

Fig. 4—Calibration curve for transmission dynamometer.

g It may be made very sensitive and accurate. The construction lends itself very easily to variation of range of application and to varying degrees of sensitiveness, since the oil pressure, and hence the sensitiveness of the instrument, depend upon the area of the diaphragm, the relative lengths of the arms of the latches *L*, and the diameter of flanges. Its accuracy is dependent mainly on the degree of accuracy of the means employed to measure the fluid pressure, of which a number of forms, other than the usual pressure-gauge, are available. The latter, however, is the more usual.

h The only power absorbed is the small amount due to the friction of the ball, or roller, bearings, and this can be determined from the pull of the retaining arm. It is unnecessary to make correction for this, however, since the amount is so small as to be negligible.

i Since the only wearing parts are the ball, or roller, bearings, which may be lightly loaded, the instrument should not be deranged easily. Because of the very small volume of oil contained in the weighing chamber, ordinary temperature changes do not affect the calibration. All parts containing oil are stationary, hence all joints may be soldered and leakage entirely prevented, which is a feature of this device.

j With suitable material and ordinary workmanship, it is believed that there is little likelihood of failure of any part of the instrument. It is conceivable, however, that the balls or rollers, although lightly loaded, might crush; the diaphragm might shear; or the stationary member, although bearing only its own weight and lubricated, might seize to the hub. Remote as are any of these possibilities, should any or all of them occur, the worst that could happen would be the tearing-off of the oil pipe and retaining arm, when the whole would revolve as a solid coupling. In no case can the coupling fail to drive the shaft because of its variation from the standard form, since, in addition to the driving latches employed to carry the load normally, the same number of connecting bolts may be employed as in the ordinary coupling, which will still hold the coupling together should the latches fail. Since, however, these latches are farther from the shaft, they should, if properly constructed, be less likely to fail than the connecting bolts usually employed.

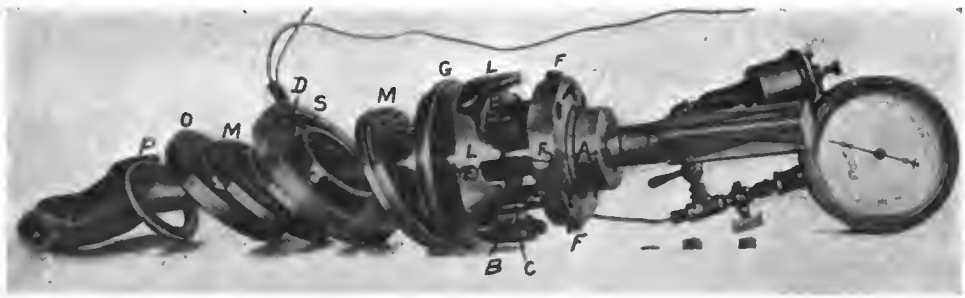

Fig. 3—Transmission dynamometer taken apart to show construction of constituent parts.

It is believed that uses for the instrument here described will suggest themselves, and it is with the hope that the device will prove of some interest to those who deal with the use and transmission of power that the matter is presented.

A NEW SOLDER FOR ALUMINUM.

The problem of soldering aluminum has troubled experts in the soldering line for many years, and most of the liquids brought out for the purpose have developed some unsurmountable drawback when put into use. As a result of this the idea became prevalent that no liquid would do the work.

However, the lack of an effective flux caused the formation of oxide, which always prevented a proper joint being made. Prompted by the conviction that without an intermediate it was impossible to make a good soldered joint, Otto Nicolai, Boppard-on-Rhine, Germany, managed to make a good flux after many years of experimental work.

But the great problem was not really solved without having a solder with the same fusing point as the flux. The inventor's next step was therefore to find a suitable solder. He ultimately succeeded in getting over this difficulty as well, so that an effective solder can now be had. An important feature is that one need only scrape the aluminum to make it clean before soldering and then to wipe the joints with the Nicolai flux.

Solder mixed with the flux is now put on to the joint and will run into the crevices by itself; it will cover surfaces of several square centimeters in area, and the joint obtained in the end is inseparable. Sheets with a joint can be hammered quite thin without injuring the joint. This solder and flux are being used at the imperial dockyard in Kiel and at the royal gunpowder factory in Spandau. At the imperial dockyard in Wilhelmshafen the inventor soldered a new bottom on to a tea kettle of the kind used by bluejackets. The length of the seam was 75 cm. A flask which had become leaky was also soldered.

This and much other work of a soldering nature was passed upon by the Government engineers and pronounced perfect, at least as far as the quality of the weld was concerned. So, Mr. Nicolai has the stamp of approval of the German Government upon his process, which, alone, speaks highly of it. This solution of the aluminum problem is a welcome one.

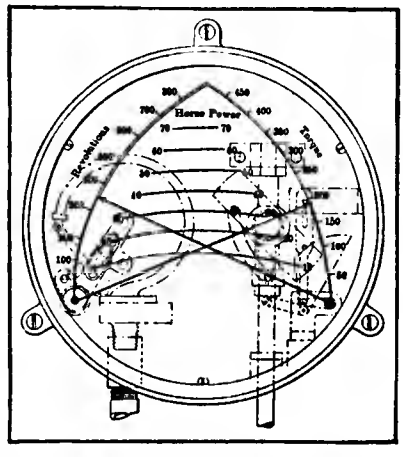

Fig. 5—Combination pressure gauge tachometer, indicating torque, revolutions per minute and horsepower.

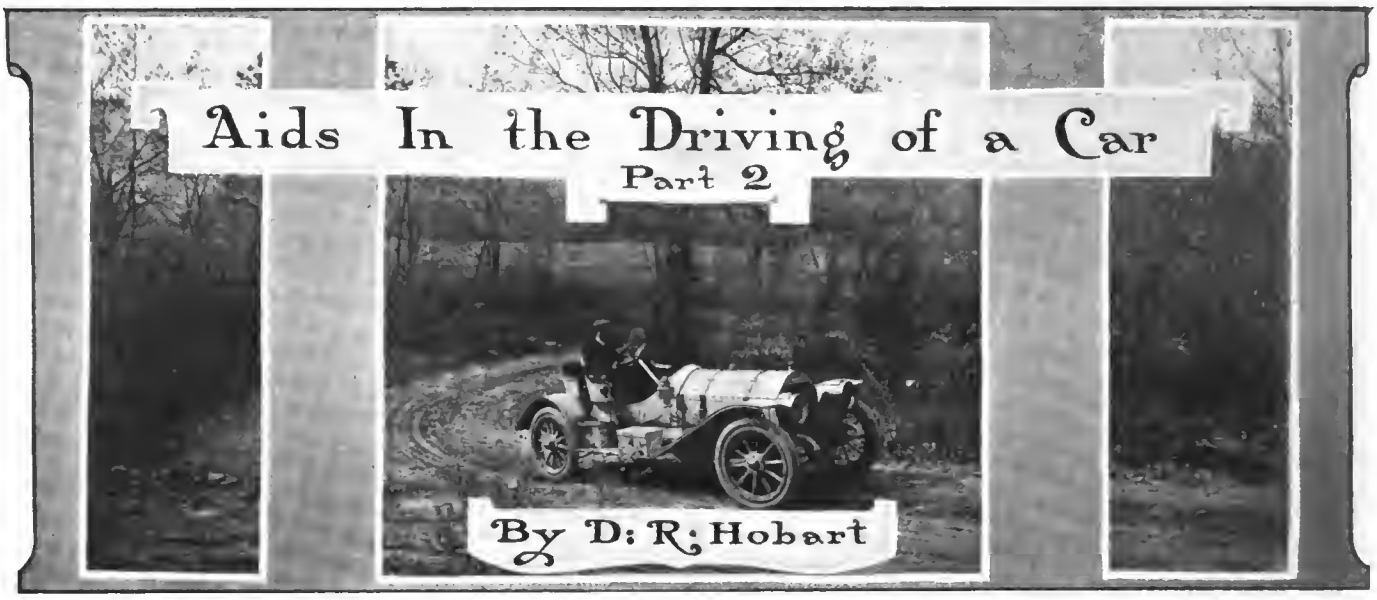


Aids In the Driving of a Car

Part 2

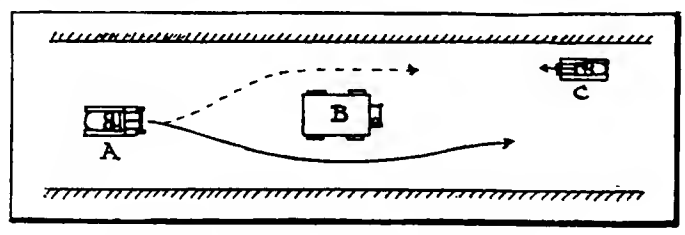
By D. R. Hobart

ALTHOUGH autoists pay attention to the mechanical details of driving, such as the adjustment of spark and throttle, gear changing and brake operation, the extremely important function of oiling is not given the care that it deserves. Since the car has been tested and adjustments have been made before leaving the factory, it is presumed that everything will continue to operate properly when on the road. To the credit of the manufacturers this is true in a large majority of cases, but even the best oiling devices suffer by neglect, sight feeds clog up or the driving belt may break, with unhappy results. The autoist should take no chances, but constantly observe the sight or circulation feeds and as soon as a cessation of flow is noted it should be investigated and the trouble repaired at once. The oiling directions given in the instruction book should be followed to the letter, and if the conditions of the run are abnormal oiling should be performed oftener than usual. In every instance an excess of lubricant is more economical than worn or broken bearings.

Caution Needed in Overtaking Vehicles—There are two general principles to be remembered in overtaking or passing vehicles on the road. These are: Be sure that there is a clear way ahead before the overtaking or passing is attempted, and never to cut things so fine that a swerve on the part of the other man will cause a mishap. Quite a large proportion of road collisions come from either of the parties concerned taking chances that the other will do the right thing, which seldom happens. In overtaking another vehicle, care should be taken to ascertain that the driver is aware of your presence, particularly if he is driving a covered vehicle or one that is noisy. It is often difficult to make the other man hear, and the chances of his swinging out are too great to warrant any risk being taken. A tendency on the part of the driver to turn off to the side of the road, apparently to let the autoist go by, may be the result of an involuntary pull on the reins or may have been done to avoid a bad place in the road, and this turning off is often followed by an equal swing in the opposite direction. In following a vehicle the autoist should not keep in the other vehicle's tracks, but should stand off diagonally so that he or one of the passengers in the car can see the road ahead and observe the actions of other vehicles. Sufficient distance should be kept so that the autoist can turn in behind the leading vehicle in case of the sudden appearance of others coming in the opposite direction. When the way ahead is clear, the autoist should pass as quickly as the nature of the road permits.

Passing Moving and Stationary Vehicles—The chief point to be remembered in passing moving vehicles is to always allow plenty of room for both. The passing of another vehicle so closely that there is hardly room for a sheet of paper between them, may be looked upon as brilliant driving, but sooner or later some one will miscalculate and an accident will occur. All passing should be done according to the rule of the road prevailing in the section of the country in which the car is being driven, as the great majority of road users follow this rule, and in case of accident the vehicle which held to the proper side of the road is generally exonerated in the courts. In passing stationary vehicles or those about to start, a strict lookout ahead should be kept for pedestrians or vehicles suddenly emerging from the rear, or in the case of a trolley car, for alighting passengers and those rushing to board the car. It is not sufficient to blow the horn and count on its being heard by those behind the other vehicle. The chances are that the sound has not been heard, and nothing but slow speed can be indulged in with safety. The same need of slow speed and extreme caution occurs in overtaking stationary vehicles as in passing them.

Passing on the Wrong Side—As a rule, all vehicles should be passed on the proper side according to the rules of the road, but there are occasions when it is unsafe to pass in this manner and the autoist has either to pass on the wrong side or wait until conditions are such as will allow him to pass according to rule. Such an occasion often presents itself in overtaking a heavily loaded vehicle or one which has been disabled and has not been withdrawn to the side of the road. Once a loaded van or truck leaves the crown of the road, it has some difficulty in getting back again, especially if drawn by horses, and the driver will generally refuse to turn aside except for other equally heavy vehicles. As the autoist is conducting a vehicle



Case When Car May Pass On Wrong Side.

of greatly superior speed and mobility than that of the truck, the latter can be considered as a stationary object for the time being and passed on the wrong side, provided the road is clear. The situation is shown in the sketch where *B* is a truck and *A* a car about to pass the truck. The road being clear, car *A* can take the course *a*, passing the truck on the wrong side. Should the course *b* be taken, a collision is likely to occur between the car and another car *C* proceeding in the opposite direction, unless great caution is exercised by both drivers. If

there is any doubt as to the road not being clear, the autoist should take no chances but wait until the way on the left of the truck is clear and then pass on the proper side. Situations like the above occur from time to time on the road and the autoist should use his judgment in coping with them. Legally it is not justifiable to depart from the rules of the road except to avoid accidents, and this should be borne in mind at all times.

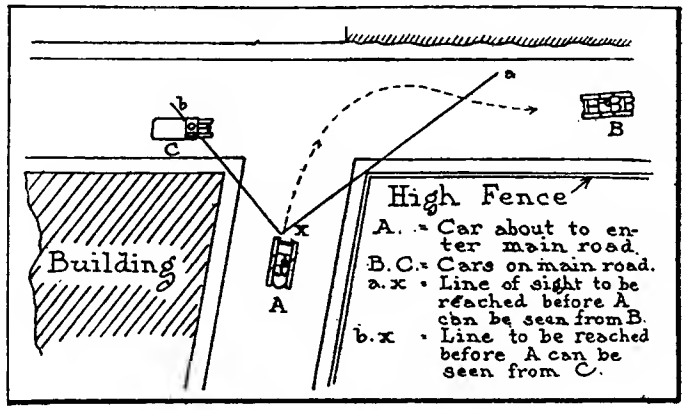
Passing Horses on the Road—The majority of horses encountered on roads frequented by automomiles to any extent, pay comparatively little attention to them, even when passed at fairly high speed, and of the remainder it is safe to say that most are not nearly so alarmed as their drivers, who communicate the alarm to the horses through sawing on the bit, shouting or dropping the reins. The exceptions are young horses or those which have not been given sufficient road driving. In passing horses, the autoist should not only observe the actions of the horse, but also those of the driver as well. If the horse exhibits signs of being restive, the voice has a very quieting effect. Expressions such as "Whoa, boy," said in a reassuring tone will in many cases be sufficient to soothe the animal until the car can pass.

The best manner in which to pass a standing horse headed in the same direction as the car is to cross to the far side of the road and drive by quietly at the legal speed. The horse will be only slightly startled, if at all, and will not bolt or back, as the alarming object and its terrors are gone. More care is necessary in passing a horse headed in the opposite direction, as the animal can see the car coming and has time to become fidgety. If the driver has the animal under control, the car can be driven past at the regular pace unless signs of fright are seen, when the car should be slowed down or stopped if necessary. The car should pass on the opposite side of the road and as soon as it is by speed can be increased in order to get out of hearing as soon as possible.

Procedure in Leading a Horse—It may be necessary in some cases to stop both car and motor and to lead the horse past the car. As a number of accidents have occurred through the horse freeing his head from the bridle through improper leading, a word on proper leading a horse will be timely. Both reins should be taken in the right hand about 6 inches from the bit and the horse patted and reassured by the voice. The autoist should then face forward and start off, walking alongside the horse's head until past the car. Should the animal rear, the grip on both reins prevents him from tearing free from the bridle and bolting. The usual mistakes made in leading are in grasping one rein only which hurts the horse's mouth and may break the bridle, and in dragging the horse along while walking backward. As a horse will not willingly walk over a man and as this is the position usually assumed by drivers when hitting the animal over the head, instead of having a soothing effect the operation is rendered harder through alarming and confusing him.

Proper Negotiation of Road Crossings—In approaching road crossings the autoist should slow down to a speed at which he can pull up on the brake within the length of his car, and blow his horn for the purpose of warning other road users of his presence. As the car approaches the crossing, a sharp lookout should be kept for traffic on the intersecting road, and as soon as the way is seen to be clear the crossing should be taken as quickly as possible. Particular care should be exercised at crossings where one road is partially or totally hidden from the other until the crossing is reached, especially in the smaller towns, as light carts, bicycles or in fact vehicles of any kind frequently emerge from the side road at speed and in the most careless manner, even when those in control are unable to see anything that is approaching on the main road. In anticipation of such performances the car should be kept to the center of the road so as to be able to turn aside to avoid a collision, as even if the horn has been blown, there is no way of knowing that the driver of the other vehicle has heard it. Even if vehicles on the intersecting road can be seen, great caution must be exercised, as there is no indication that they are going to continue along the side road nor in which direction they will turn into the main road. Passing partially hidden road crossings at speed is absolutely dangerous because of the long chances which reckless autoists take at such places.

On Approaching a Blind Turn—Frequently encountered in suburban towns is the blind turn, where a cross street or road terminates in one of the main roads and the view from either road is obscured by buildings or fences until the turn is reached.



Illustrating Blind Turn and Its Negotiation.

At such turns the chances of accident are greater than at road crossings, as at these latter places an autoist has three directions in which he can turn to escape collision while at blind turns there are but two, with the chances in favor of the car on the side road. Referring to the sketch, *A* is a car about to enter the main road and proceed thereon in the right-hand direction, and *B C* are cars proceeding along the main road. Owing to the high fence on one side and the building on the other, *A* cannot be seen from *B* or *C* until the lines *ax* and *bx* are reached, nor can *B* or *C* be seen from *A*. The sound of a horn from either road likewise cannot be heard from the other. Under the circumstances, car *B* should keep to the center of the road as in negotiating road crossings and car *C* should keep to the right-hand side of the road and proceed cautiously. When the car *A* makes the turn into the main road, it should take the path shown by the dotted line, swinging well out to avoid a possible collision. Car *B* has thus an opportunity to turn aside and avoid *A*. Should *A* turn to the left into the main road, car *C* is in no danger even if the driver of the former car cuts the corner closely. The positions shown in the sketch should be assumed at all times when approaching a blind turn whether the presence of a car on the other road is known or not.

The Right of Way at Turns and Crossings—Regarding the right of way at turns and crossings, the vehicle which arrives first has the priority of passage according to actual road practice. In case of a "dead heat" between two cars, it remains for both drivers to agree as to which shall proceed ahead of the other, the driver yielding the way giving a signal with the hand. Generally speaking, horse traffic gives the precedence to automobile traffic as a matter of safety, but the autoist should not consider that he has the absolute right of way over all other road users for this reason. Every user has equal rights on the road, but because the autoist has a vehicle of great physical superiority due to its weight and speed, he is not entitled to lord it over those not so well equipped. It does no harm to yield the road to a horsed vehicle even if the action necessitates a change of gears or a stoppage of the motor. On the contrary, the courtesy shown will do much toward removing the prejudice against automobiles in that portion of the country. In general, the autoist should exercise his discretion as to what is proper under the circumstances, departing from road practice if necessary, and his individual sense of fair play should cause him to have regard for the rights of others at all times.

(To be continued.)

AN INTERESTING NEW AIR COOLING SYSTEM

ADDITIONAL light is being shed upon the subject of air—or, as it is sometimes called, direct cooling, by a number of experimenters working along new and radically different lines. The idea of an Englishman, E. H. Morgan, is to circulate air through the regular water jackets, so that it circulates around the heated cylinders. The use of air as a medium in the water jackets means less weight, and less complication. The latter, in particular will be emphasized by Morgan's scheme, for he proposes to dispense with the fan and induce the air to flow by the action of the exhaust in an ejector pipe.

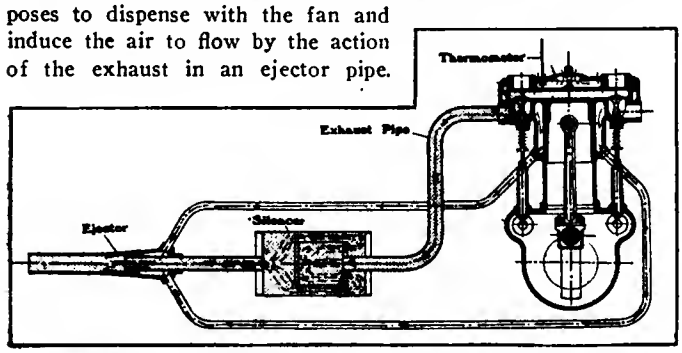


Diagram of Morgan's Air-Cooling System Showing Action.

In this way, as the cut shows, the pump and its drive is not only dispensed with, but the fan and fan drive, is also done away with. The muffler used (the English call it a silencer) is a very simple one, being merely a cylindrical shell about nine inches long by seven inches in diameter. Within this is placed another drum of smaller dimensions, to which the end of the exhaust pipe is fastened. The gases are allowed to flow into the one end and strike the other, when they turn and escape by the front end, which is perforated. Once more, the shape turns them through 180 degrees, and thence they escape into the induction pipe or ejector as it is marked on the cut.

This is of large diameter and the gases pass rapidly through it at a high speed, this varying with the work which the motor is doing and not with the speed alone. The latter is said to be the chief objection to the ordinary method of blowing air against the exterior of the cylinders by means of a fan or blower operated from the engine itself. This means that the speed of the fan, and consequently the speed and volume of the air, vary with the rotary speed of the engine. Now, at the time when the greatest amount of air is necessary, as at slow speeds on a hill the least amount is being furnished.

This has been carried beyond the theoretical point by means of thorough tests. The latter were made on a Milnes-Daimler four-cylinder engine 96 mm. bore by 130 mm. stroke (3¾ by 5⅛), the rating for which would be 22½ horsepower.

In the actual test, the motor developed much power in excess of this. The temperature of the air within the water jackets just previous to the commencement of the run was 70 Fahr. Three minutes after applying the load to the prony brake (ten minutes after starting the engine), it had risen to 190 degrees. Five minutes later 240 degrees was reached, and a further running of fifteen minutes caused it to go to 275 degrees.

Mr. Morgan ran the engine with very little oil purposely, and many thought that he was courting disaster to use so little, in view of the high temperatures. Examination of the exhaust showed not the slightest trace of oil, and no effects of the lack of it were observable. The engine ran with perfect regularity during the test, maintaining a speed of 840 revolutions, at which the power developed was 38. After 35 minutes' continuous running the prony brake band seized, due to lack of water, and the motor was stopped. At this, the temperature within the jackets rose to 440 deg., and some difficulty was experienced in restarting.

The engine was started again, and run at the same speed but with a lower load, so that the power was but 31.5. This run continued for over 20 minutes, when trouble with the brake band, due to lack of water, caused the second stop, and with it the observed temperature in the jackets again rose. This apparently had no other effect than to burn the film of lubricating oil from the cylinder walls. There was no evidence of preignition at any time during the tests, and the average of careful observations of the temperature of normal running showed it to be in the neighborhood of 275-280 deg. Fahr.

This was by far the most unsatisfactory of all the tests made, but the figures for the others are not available. It may be seen that the normal figures deduced from a not wholly satisfactory test are just midway between the maximum figure for water-cooled motors and the recommended temperature for air-cooled engines, namely, 205 deg. for water and 350 deg. when air is used. These two average 278 deg.

THE AUTOMOBILE CALENDAR.

Shows, Meetings, Etc.

Nov. 6-13.....Atlanta, Ga., Auditorium-Armory, National Automobile Show.

Jan. 8-15.....New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Feb. 5-12.....Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

May 28-30.....Denver, Col., Reliability Contest, Pueblo and return, Denver Motor Club.

May 29.....Wilmington, Del., 106-Mile Sealed-Time Run, Delaware Automobile Association.

May 31.....Wilkes-Barre, Pa., Annual Hill Climb, Giants' Despair Mountain, Wilkes-Barre Automobile Club.

May 31.....Bridgeport, Conn., Annual Hill Climb, Sport Hill, Automobile Club of Bridgeport.

June 1.....New York City, Start of Transcontinental Contest to Seattle, for Alaska-Yukon-Pacific Exposition, M. Robt. Guggenheim Trophy.

June 5.....Albany, N. Y., Hill Climb, Kenwood Hill, Albany Automobile Club.

June 9.....National Orphans' Day.

June 12.....Worcester, Mass., Annual Dead Horse Hill Climb, Worcester Automobile Club.

June 12-14.....New York City, Catskill-Berkshire Endurance Contest, New York Automobile Trade Association.

June 14-18.....Philadelphia Reliability Run to Pittsburg and Return, Quaker City Motor Club.

June 14-21.....Annual 660-Mile Spring Tour Maxwell-Briscoe Motor Club, New York City via Waterbury, Stockbridge, Newburgh, Delaware Water Gap, Philadelphia, Atlantic City, to New York.

June 17.....Readville, Mass., Track Race Meet, Bay State Automobile Association.

June 18-19.....Chicago, Stock Chassis Race for Cobe Trophy and Light Car Race.

June 21-26.....Binghamton, N. Y., Fourth Annual Endurance Run, Binghamton Automobile Club.

June 22-28.....Albany, N. Y., Fifth Annual Tour, Bretton Woods, Portsmouth, Boston, Albany Automobile Club.

June 24-26.....Montreal, Blue Bonnets Track, Race Meet, R. M. Jaffray, Manager.

June 25-26.....Philadelphia, 24-Hour Track Race, Quaker City Motor Club.

July 3 and 5.....Wildwood, N. J., Straightaway Racea, Motor Club of Wildwood.

Letters Interesting and Instructive

TIME FOR VALVE GRINDING.

Editor THE AUTOMOBILE:

[1,889.]—Will you please advise me how often I should grind in my valves. The motor is a four-cylinder, water-cooled, one of 30-horsepower, and recent make.

Carbondale, Pa. R. T. TRUESDALE.

There is no hard and fast rule which can be given aside from grinding when it is necessary. A careful driver may get four to five thousand miles out of his valves with one grinding, while another, with the selfsame car and engine, may only get one or two thousand miles per grinding. There are many factors which enter into the life of a valve seat, and in the frequency of grinding all of them have to be taken into account. Some of these are: imperfect cooling of the seats, as described in THE AUTOMOBILE for last week (May 13 issue); too strong springs, which cause hammering and thus wear out the seats prematurely; over-lubricating, which causes spitting and sooting, both of which reduce the active life of the valve seat.

Other causes are contributory negligence on the part of the driver in not examining them more often, which examination often results in the discovery of something in the way of soot or dust caught in between the valve and seat, and being gradually pressed into the latter.

A habit followed by professional drivers is to grind valves as soon as a certain distance has been covered, this being predetermined by experience with a single or many cars. This habit might well be followed by amateurs, as soon as they have driven enough to determine the critical mileage.

ANOTHER ROTARY VALVE

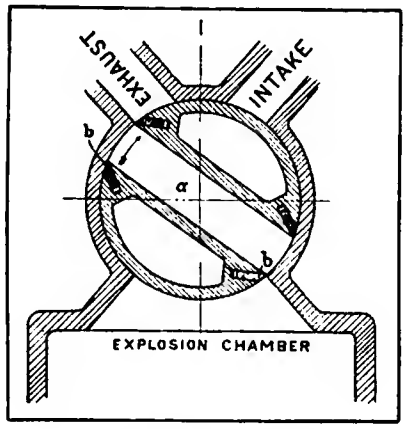
Editor THE AUTOMOBILE:

[1,890.]—I have noticed the excellent article in "The Automobile" for May 13, by W. F. Bradley, in which he speaks of a new Italian engine with a rotary valve. Has not an American motor been built with a rotary valve and if so, will you please tell me something about it and where it was built?

Philadelphia, Pa. H. F. WHITE.

In 1907 Messrs. Howard and Frayer, the latter formerly chief engineer for the Oscar Lear Company, builders of the Frayer-Miller car, built for M. W. Kouns, of Sandusky, O., an air-cooled engine with rotary valves, one rotary taking the place of two ordinary reciprocating valves. These were placed in the cylinder heads, lengthwise of the engine, and a single camshaft driven from the crankshaft by means of worm and gear drives all of them.

The valve, shown in the illustrations, rotates at one-fourth the crank speed, so that it completes a cycle in one-half a revolution. The exhaust works first in the direction of rotation, after which the passage of the incoming charge cools the valve. Circular rings on the full part and straight strips, spring-actuated, at the cut part, serve to make the valve gas-tight. An additional advantage which this device had was the ability to reverse. Upon the vertical shaft is placed a pair of gear- and a couple of



Rotary Valve Shown in Section.

dog clutches. By using one, the valves rotate in one direction and with them the engine. When the other clutch is thrown into mesh, the valves, and with them the engine, turn in the opposite direction.

The second illustration shows the air-cooled cylinders to which the valves were fitted, and one of the valves.

These engines were to be marketed by the Ohio Manufacturing Company, Upper Sandusky and Columbus, O., in sizes from 12 to 40-horsepower, but whether this firm is still in business or not is more than can be said.

Charles E. Duryea, who was formerly in business in Reading, Pa., building water-cooled engines, is a prominent advocate of the rotary valve, and his design, in which the valve is water-cooled, has many points of superiority over the one shown.

Cylinder and Valve as Actually Made.

FIXED FIRING POINT PUZZLES.

Editor THE AUTOMOBILE:

[1,891.]—Will you please explain to me the action of a magneto which allows with the disposal of the spark advance lever? These are, I believe, said to have a fixed firing point.

Dayton, O. A SUBSCRIBER.

The answer is that the intensity of the current increases and the moment of maximum intensity advances, as the speed of the armature increases. Therefore, as the engine speed increases the timing automatically adjusts itself to the conditions. The opposite also holds true, so that for starting the moment of maximum intensity is so far retarded that it is safe to crank the engine over. All of this allows of dispensing with the usual spark advance lever, with consequent simplification.

DIFFERENTIAL ELIMINATION.

Editor THE AUTOMOBILE:

[1,892.]—In reference to the article in the April 29 issue of "The Automobile" regarding the Ampere car, will you please advise me at what angle the inside road wheel is released on a curve; also, whether the current is wholly cut off at this certain point, or is there a preliminary gradual weakening of the current?

New York City REGINALD E. JORDAN.

To quote from the description of the Ampere car, on page 704, "The differential will at once be missed, and the resulting simplification noticed." And further along, "When current is turned into the magnet *E*, * * * the corresponding plate *P* * * * is attracted and as long as the current passes and energizes the magnet, is driven by the rotating axle. As soon as the current is cut off, the wheel is freed and is no longer driven from the motor."

This explains the action of the device. Now for the current, quoting once more from the same page: "The steering gear turns free up to a certain angle, at which it automatically cuts off the current to the inner wheel." The manufacturers advise that this cutting off action begins to manifest itself at an angle of 5 degrees out of a straight ahead line, beyond which the current gradually weakens continuously up to 35 degrees, at which latter angle the whole of the current is cut off and no flow of current to these magnets takes place until the wheels are turned back.

The action on straightening the wheels is just the reverse of this, when the wheels are turned back to 35 degrees out of a straight ahead line, the current begins to flow weakly, but constantly increasing in strength up to 15 degrees, at which point it has its full strength, and the wheel is fully engaged.

The makers say that these two angles have been carefully determined experimentally, as the result of several years of test-

ing work in this field of endeavor, and are therefore correct for this class of work.

This solution of the problem of the differential is an excellent one, and well worthy of imitation by our American manufacturers in their striving for simplicity.

GAS TURBINES.

Editor THE AUTOMOBILE:

[1,893.]—Will you please tell me something about the gas turbine, its prospects, a description of it, and list of books on the subject? J. W. FRANKLIN.

New York City.

The subject is too large to be gone over in this space, but it might be said that some experimental work has been done on gas turbines, more particularly on the other side. Some work has also been done in

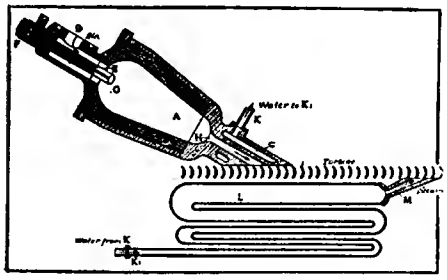


Diagram of Gas Turbine.

this country. None of the resulting machines have been declared successful, nor have they been put on the market for sale.

A prime reason for the lack of success in this direction is the impossibility of an air or, better, a gastight casing with frictionless rotation. If the former is secured, it is at the expense of the latter, and the resulting output will not be enough greater than from the reciprocating type to warrant the use of the excessive speeds of the turbine which run ten times the ordinary.

So, too, if the latter, frictionless rotation, is secured at the expense of the gas tightness, the result would not warrant a change to the newer prime mover.

In "Steam Turbines," by Stodola, a chapter is devoted to this interesting subject, as is also the case in Neilsen on Steam Turbines. A new work is entitled "Steam Turbines," by Moyer, and in it will be found several chapters on the subject. This paper, THE AUTOMOBILE, has also spoken of it at different times, although no extended article has ever been published.

We are giving, for Mr. Franklin's benefit, two reproductions of gas turbines as proposed by prominent experimenters. One of these uses steam in combination with gas, the effect of the former being to cool the blading of the rotor as heated by the exceedingly hot gases of combustion. In the view of this, the larger of the two, *A* is the combustion space. *B* the carborundum wall. *F, D, G* and *E* are the air and gasoline feeding pipes. *I* represents the rotor of the turbine. *C* is the nozzle water jacket. *L* shows the small boiler receiving hot water from the water jacket *C*, and also heated by the exhaust gases around the outside. *M* is the steam nozzle.

The other is somewhat similar, the use of carborundum for the combustion chamber walls, water for cooling, and all features of the first except the use of steam, being found as on the one first described.

PROOF OF ACID IN OIL.

Editor THE AUTOMOBILE:

[1,894.]—Will you please give a simple method of testing lubricating oil for acid contents, one that any amateur could use. I understand the presence of even a trace of acid in the oil will, in time ruin the ball bearings and other fine parts of my car. H. D. BLAKESLEE.

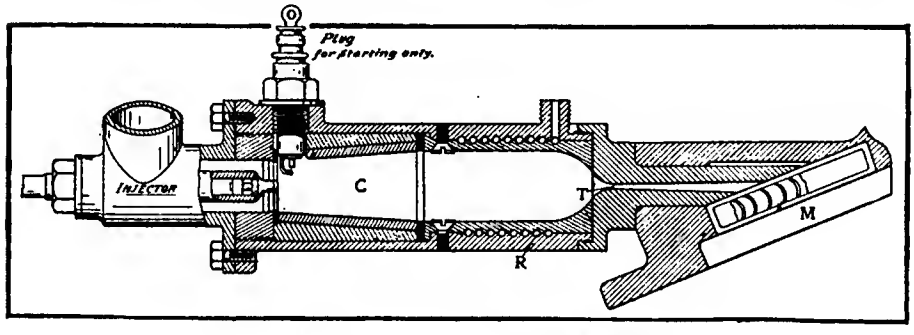
Detroit, Mich.

You are right, a trace of acid in the oil will ruin the balls and races of bearings.

Pure mineral oils contain little acid, and what they do contain is readily determined. Vegetable and animal oils, on the other hand, all have oil contents and under the action of heat these may be liberated.

A simple home test may be practiced as follows: Secure from a druggist a solution of sodium carbonate in an equal weight of water. Place this in a small glass bottle or vial. To test an oil, take a small quantity of the lubricant, and an equal amount of the sodium solution. Put both in another bottle, agitate thoroughly, and then allow it to stand. If any acid is present, it will settle to the bottom as a precipitate, the amount of the precipitation being a measure of the amount of acid present.

Another method is to allow the acid, if there is any, to attact some metal. To do this proceed as follows: Soak a piece of cloth or preferably, wicking in the oil suspected of containing acid. Select a piece of steel at random and polish it to a bright surface. Wrap the steel in the soaked rag or wicking, and place in the sunlight but protect from wind or weather. Allow it to stand several days, and if there is no sign of etching of the surface, repeat with a freshly soaked rag, being careful to use the same oil as before. After two trails if no sign of the etching appears, you may take it as free from acid.



Another Gas Turbine Without the Steam Jet.

LIGHTER THAN GASOLINE.

Editor THE AUTOMOBILE:

[1,895.]—Will you please tell me if there is any known colored liquid which is lighter than gasoline so that I could use it to make a gauge glass with? What I want is something which will float on gasoline so that I can arrange a gauge glass outside of the tank, and have the colored liquid, by floating on top of the gasoline, indicate the level of the fuel within the tank.

New Rochelle, N. Y. R. R. ROBERT.

The three necessities for the liquid to serve your purpose would be: colored, lighter than gasoline, and nox-mixable with the latter. The lightness of gasoline is measured with the hydrometer, on which (Baume) ordinarily 70 is the figure. This is equivalent to about .71 specific gravity. Now from a list of liquids of known specific gravity select one lighter than this. Here is a list of liquids and their specific gravities:

1.	Rhigoline	.615-.625
2.	Petr. Ether	.630-.640
3.	Sulph. Ether	.716
4.	Petroleum	.780-.880
5.	Kerosene 135 test	.786
6.	Kerosene 150 test	.788
7.	Pure Alcohol	.793
8.	Alcohol 95 per cent	.816
9.	Alcohol 94 per cent	.820
10.	Fuel Oil	.828
11.	Alcohol 90	.834
12.	Naphtha	.848

From this you can see that but three liquids qualify as lighter, numbers 1, 2 and 3, all of which will mix with gasoline, so that nothing that can be called to mind will answer your purpose. An additional fact which you should bear in mind is that such a proceeding as you have in mind is dangerous, and should not be tried. If the glass became broken in any way the inflammable gasoline would be free to flow out and ignite, which might mean the loss of your car.

KEROSENE AS FUEL.

Editor THE AUTOMOBILE:

[1,896.]—Will it be possible for me to use kerosene as a fuel for my double opposed 16-horsepower engine without expensive changes in construction? I am greatly interested in the fuel question and want to experiment with it, but do not want to spend a lot of money. R. H. OTIS.

Colorado Springs, Col.

Kerosene has been and can now be used in carbureters designed for gasoline, but not with any marked degree of success. It is fair to assume that you wish to determine the comparative cost of the two fuels. It is not advisable to use an ordinary carbureter, without alterations which will give kerosene a fair chance.

The main difference between the two lies in the difficulty of vaporizing the heavier fuel with the available heat. In many kerosene vaporizers this difficulty is overcome by heating the fuel before as well as during vaporization.

U.S. SEEKING THE REMEDY FOR ROADS' WEAR AND TEAR

Those Who Helped to Do the Work at the Long Island Test, Held on Hillside Avenue, May 20.

Reading from left to right: Lieut. Warren T. Hannum, Engineer Corps, U. S. A., Washington; John P. Coghlin, president, Worcester Automobile Club; Vernon N. Pierce, chief engineer, Office Public Roads; F. H. Elliott, secretary A. A. A.; Col. Spencer Cosby, Supt. Buildings and Grounds, Washington; Jos. A. Anglada (in back), New York City; David Sheridan Stanley, Major Quartermaster, U. S. A.; Major Jay Johnson Morrow, Engineer Corps, U. S. A.; L. W. Page, Director U. S. Office Public Roads; P. St. J. Wilson, State Highway Commissioner of Virginia; Alex Floyd Armstrong, New York State Department of Highways; George C. Diehl, Engineer Erie County, N. Y., and chairman A. A. A. Good Roads Board; Herman F. Cuntz, M.E., of A. L. A. M.; James Owen, C.E., representing New Jersey State Commissioner of Roads; Coker F. Clarkson, engineering department, A. L. A. M., and Thomas J. Fay, Society of Automobile Engineers, New York City.

FULLY alive to the needs of the moment, the Office of Public Roads of the United States Department of Agriculture, under the supervision of Director Logan Waller Page, is seeking to solve the natural sequence of the problem presented by the greater use of the highways through the coming of the motor-driven vehicle. Some time ago experiments on road surfaces were made in the vicinity of Washington, and again on Thursday of last week another series of tests took place on Hillside avenue, in Jamaica, L. I. These tests were brought about with the co-operation of the good roads board of the American Automobile Association, of which George C. Diehl is the chairman. In attendance were the highway commissioners, or their representatives, from nearly a dozen different States, officers of the Engineering Corps of the United States Army, a plenteous delegation from the Office of Public Roads, and automobilists of national reputation.

While the results were not as thoroughly satisfactory as many wished, at the same time undoubted progress was made in the premises, and the facts adduced will be utilized in arriving at the ultimate result.

Hillside avenue is in a more or less worn-out condition and appears to be a combination of a macadam and gravel road, with frayed sides. Frequently the cars traveled over a part of the real road and the dusty side. There were trials at low speed and high speed, and brake tests, with and without chains and anti-skids, and horse-drawn vehicles entered into the producing of photographic evidence, which was supplemented by the tape measure.

A technical committee composed of Herman Cuntz and Coker F. Clarkson, of the A. L. A. M.; Thos. J. Fay, Jos. F. Anglada and O. A. Stranahan, of the Society of Automobile Engineers, and C. F. Drake examined the cars carefully in order to be able to fix upon the value of the test data, taking into account all the factors that might have bearing on the results. A summary of the observations made by the technical committee will best tell the story, though it will be at the expense of some time, many more tests, and much discussion before the whole story will be told, reaching conclusions of a dyed-in-the-wool character.

There were 36 tests involving speed, taking into account the several makes of tires, and with an idea of judging of the amount of dust raised photographs were taken from all angles. Then the effect on the roadbed was observed by the committee. In the brake tests the White steamer, with tires on the rear wheels in which the word "Firestone" was embossed, had the advantage of excellent traction, and at the same time it was not actually necessary to use chains. In these severe brake tests it was adequately indicated that the tread of the tires was not damaged, although, of course, the tread did indent the roadbed when the steamer, going at 40 miles an hour, came to a dead stop inside of 140 feet, and again when going at 30 miles the car came to a stop in 74 feet.

In the speed trials when chains were applied it was expected that they would do much damage relatively, and it came as a surprise to the observers when it was found that the chains had no such effect at all. As a matter of fact, the chains did not damage the road as much as smooth tread tires when the speed of the car was high enough to cause slipping to a considerable extent. It was the common belief, taking such evidence as was afforded, that under ordinary conditions chains do not damage the roadbed, and when the speed of a car is high, in the absence of some such equivalent as the Firestone tread, the chains would seem to be an actual advantage from the point of view of the maintenance of the road.

On the whole the tests were a little tame during the speed trials, and it was not until the brake tests were innovated that the large party of road builders and automobile engineers essayed to become particularly interested. It was not anticipated that so much good information could be had in the simple process of trying out cars for the purpose of determining the distance in which they could be brought to rest. Nor was it supposed that a mounted policeman going at 25 miles per hour would experience difficulty in stopping his horse inside of 152 feet. But No. 3815 failed to do better, and he made a splendid run of it, being a veteran of the U. S. Cavalry, finely mounted, and a horseman beyond question. This same officer, going at a rate of 10 miles per hour, came to a stop inside of 17 and 12 1-2 feet respectively, as the result of two trials.

The motorcycle test was of interest, and it was also one of the surprises of the day. The motorcycle, going at 40 miles per hour, stopped inside of 157 feet, thus showing that the mounted policeman and the cyclist are about on an equal footing.

The span of horses, hitched to a rig, would not stop in an

orderly manner at all when the pistol was fired as a signal to the driver, but in the absence of the shot the same horses, going at a speed of 10 miles per hour, were brought to a stop inside of 27 feet. The carriage used was a frail affair, and the horses would be classed as a little short of "ginger." As the affair turned out, the horses failed to come to a stop any quicker than the automobiles under the same conditions of speed, as the following tabulation will adequately testify to.

AUTOMOBILE BRAKE TESTS AS MADE BY THE COMMITTEE.

Car.	Miles Per Hour.	Stopping Distance in Feet.
Simplex	20	42
Simplex	30	109
Simplex (empty tonneau)	40	187
Simplex (three in tonneau)	40	146
Simplex	25	70
White Steamer	20	41
White Steamer	25	53
White Steamer	30	74
White Steamer	40	140
White Steamer	10	16
Peerless	20	65
Peerless	28	96
Peerless	40	151
Peerless (steel studded tires)	20	55

One test showed that weight over the rear wheels, when they are the traction members, influences the situation to a considerable extent, in that a car can be brought to rest in a much shorter distance when the tonneau is provided with a weight of passengers. The Simplex car, with the tonneau empty, was brought to rest inside of 187 feet, and the same car with three average weight passengers in the tonneau came to rest inside of 146 feet.

During the dust trials the motor vehicles were operated at speeds of 10, 20, 30, 40 and 50 miles per hour. The Fiat Cyclone and the Simplex "50" were driven at the utmost speed when the condition of the road permitted, and maximum speed of 78 miles per hour was attained by the Fiat and 71 miles per hour by the "50" Simplex. Above forty miles an hour the speeds were most carefully determined by a chronograph operated by Dr. L. J. Briggs, of the Department of Agriculture, Washington, D. C.

While Director Page would not make any official statements regarding the value of the work done, it is believed that the experiments were satisfactory. It is understood that when the photographs have been developed, the moving picture films studied and the mathematical problems figured to a nicety, Mr. Page will issue a formal report from Washington.

Among those who were present as interested spectators and scientific observers were:

L. W. Page, Director U. S. Office Public Roads, Washington, D. C.
Col. Spencer Cosby, Superintendent of Buildings and Grounds, Washington, D. C.
Maj. Jay Johnson Morrow, Corps Engineer, U. S. Army, Washington, D. C.
David Sheridan Stanley, Major Quartermaster, U. S. Army, Washington, D. C.
Lieut. Warren T. Hannum, Corps Engineers, U. S. Army, Washington, D. C.
Vernon N. Pierce, Chief Engineer, Office Public Roads, Washington, D. C.
Dr. Lyman J. Briggs, Physicist, Dept. of Agriculture, Washington, D. C.
L. L. Williams, Official Photographer, Dept. of Agriculture, Washington, D. C.
Roy Crandall, Expert, Dept. of Agriculture, Washington, D. C.
James C. Wonders, State Highway Commissioner of Ohio.
Col. Wm. D. Sohier, State Highway Commissioner of Massachusetts.
Francis A. Price, State Highway Commissioner of Delaware.
P. St. J. Wilson, State Highway Commissioner of Virginia.
Alex. Floyd Armstrong, State Dept. of Highways, Albany, N. Y.
R. D. Beman, Deputy State Highway Commissioner of Pennsylvania.
James Owen, C. E., representing State Commissioner of Roads of New Jersey.
James R. Rabiin, Chief Engineer, Metropolitan Park Commission, Boston.
George Lyman Rogers, counsel, Metropolitan Park Commission, Boston.
Jesse T. Vogdes, Chief Engineer and Superintendent Fairmount Park, Philadelphia.
John J. McLaughlin, Chief Engineer Borough of Queens, Long Island.
George C. Diehl, Engineer Erie County, N. Y., and Chairman Good Roads Board A. A. A.
Herman F. Cuntz, M.E., Association Licensed Automobile Manufacturers.
Coker F. Clarkson, Engineering Department, A. L. A. M.
Charles Thaddeus Terry, Chairman A. A. A. Legislative Board, New York.
Frederick H. Elliott, Secy. American Automobile Assn., New York City.
John P. Coghlin, President Worcester Automobile Club, Worcester, Mass.
Fred J. Wagner, official A. A. A. starter, New York City.

DINNERS "ALL HOT" SERVED A L'AUTO.

PARIS, May 23—How to deliver a dinner all hot from the establishment to a customer's house is a problem that has puzzled many a French caterer specializing in high-class dinners served *à domicile*. The problem is not confined to complete dinners, for every restaurant proprietor has some specialty that he is constantly called upon to furnish promptly, fresh and hot.

The way out of the difficulty was the automobile, and the vehicle most suited to this particular class of work was the Roval, a French production, with its power plant, a single cylinder De Dion, set over the rear axle and transmitting by means of a very compact gear box and clutch to the road wheels through side chains. Such an arrangement left the whole of the vehicle ahead of the rear axle free for bodywork, while at the same time leaving the engine as accessible as if it had been under a bonnet forward. The traveling cook shop is the usual type of Roval car with special heating arrangements. The body is divided into three distinct compartments, reached through the two side and the one front doors, and each one maintained at a correct head by pipes through which the exhaust gases and the cooling water circulate. A sheet-metal lining backed with felt retains the heat sufficiently to assure any of the dishes being carried to customers as hot as when they came out of the oven.

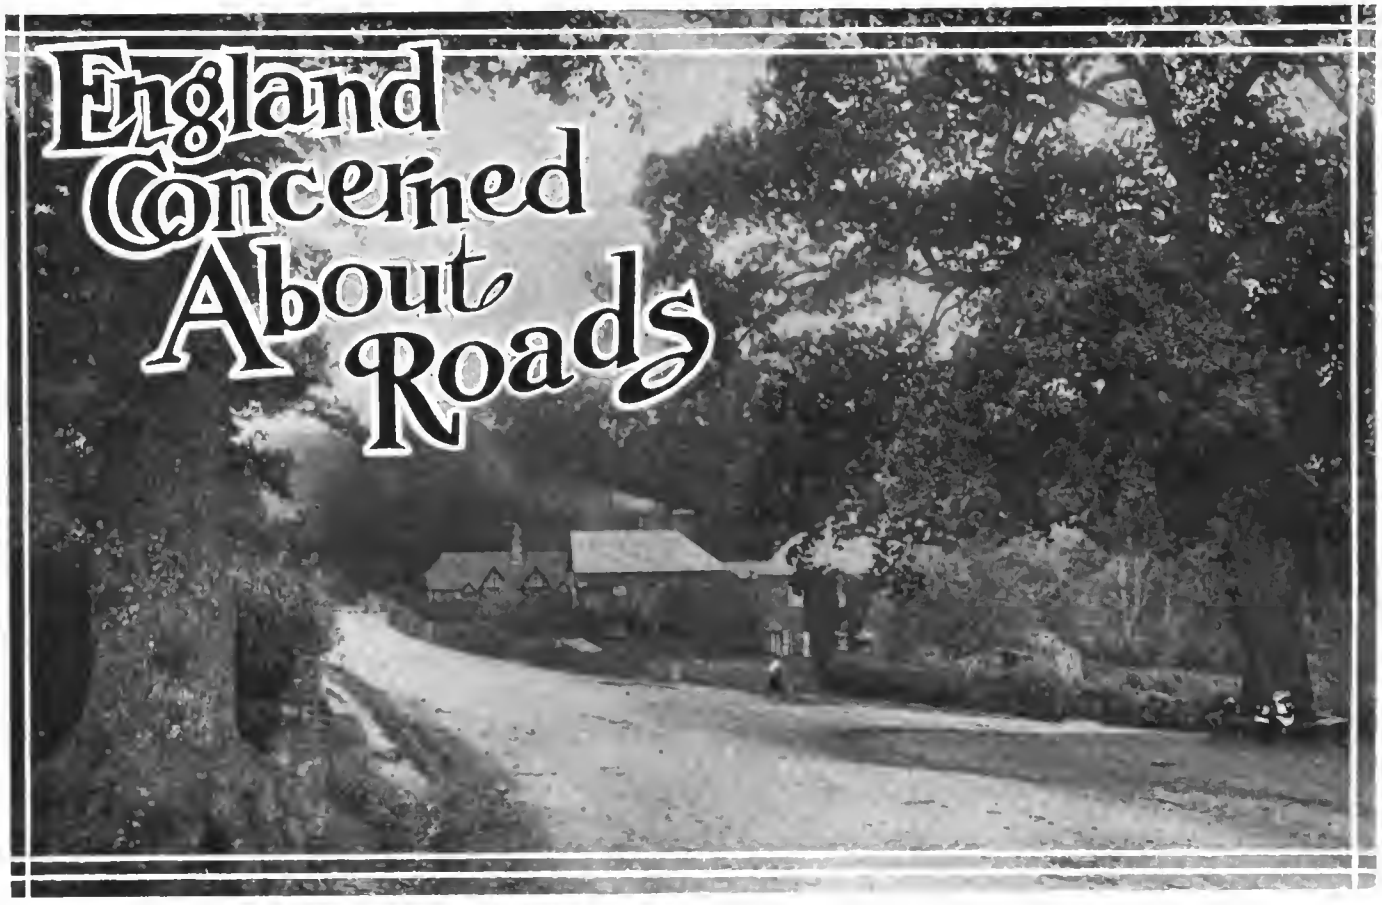
COMMISSIONERS STUDY CLEVELAND ROADS.

CLEVELAND, May 24—Franklin county commissioners will spend several days in this city next week studying the roads in and around Cleveland, with a view to improving their own along the same lines. While here the commissioners will be entertained by the Ohio Good Roads Federation, of which M. M. Maxwell, well known in automobile circles in northern Ohio, is secretary.

White Steamer in the Brake Test.

Fiat Cyclone Traveling at Speed.

England Concerned About Roads



A Typical Stretch of Highway in the British Isles, Where There Is Much Concern About Road Preservation.

LONDON, May 15—Interest unquestioned was manifest in the National Road Conference, organized by the County Councils Association, and the result of the recent sessions in London indicates that England is certainly concerned about the future of its roads. Papers innumerable were presented, and the subject was attacked from almost every point of view.

Resolutions adopted embrace a system of standardizations to facilitate the collection of facts about roads and traffic; classifications of all roads under the two headings, primary and secondary; increased government grants for the maintenance of all primary roads; codification and consolidation of the highway law; the use of tar and similar means for rendering roads waterproof; power to close roads temporarily to heavy vehicles at times when serious damage would be done by them; legislation to prevent any vehicle from bringing mud on to the roads upon its wheels; additional regulations restricting the weight of vehicles in relationship to their speed, and to the size and nature of their wheels; application of all funds derived from motor taxation to the improvement of the road.

A summary of a few of the most important papers will indicate more than anything else the diversity of the proceedings and the thorough manner in which the entire matter received consideration.

First Damage by Horse-Drawn Traffic: Then the Auto.

The passage of vehicles over a road produces several effects which it is important to distinguish. There is first, the grinding and crushing action of the wheels and horses' feet on the surface; secondly, the effect of the load in giving rise to bending and cross breaking strains throughout the whole thickness of the road coating.

Another damage that has now to be met is the scrubbing off of the road surface owing to fast motor traffic.

Almost the whole of this damage results through the roads being constructed of a water-bound granite, which in itself must of necessity be to a large extent friable.—[Albert D. Greatorex, M.I.C.E., Borough Engineer and Surveyor, West Bromwich.]

A very simple and decisive demonstration could be made to settle the question whether it is horse traffic that acts primarily and directly in disintegrating the highways. Let a short loop be made at a convenient place where the road is frequented by horse and autocar traffic. Let both sides of the loop be laid down exactly in the same way, and direct each class of vehicle to use one side of the loop only. I can say from my own experience that the result is certain. Where I live in summer there are two avenues. On one there is practically no horse traffic, and the autocar tracks are smooth and free from holes. On the other there is daily horse traffic—railway and tradesmen's carts, etc. On that avenue holes are constantly forming and have to be filled up. One can watch from day to day the formation of these holes by the picking and crushing action of the horseshoes and narrow metal tires.—[The Right Hon. Sir J. H. A. MacDonald, K.C.B.

In the first place the greatest creators of dust may be taken to be the hoofs of animals. Although wheels cerate dust also, even when rolling over the road without exerting any propelling force, they do not make dust to anything like the same extent.

The second most potent creators of dust are narrow-tired, heavily-laden carts.—[The Right Hon. Lord Montagu of Beaulieu.]

Use of Various Surface Preparations.

To cope with the dust nuisance, surfaces have been sprinkled with calcium chloride solution, and, although the nuisance has been somewhat minimized, the success has not been great. On each section of road that has been sprinkled in the manner indicated it has been noticed that the surface has worn into holes more rapidly than the adjoining surfaces which were not sprinkled.

With the present experience the author is of opinion that tar spraying or painting the surfec of a road well constructed with hard stone on a strong foundation promises the best and most economical results, both in the matter of dust abatement and suitability for modern traffic. Waterproofing the roads in this manner enables the camber of the road to be reduced to a minimum. Care should, however, be taken to properly construct the road with hard surface material on a sound foundation, and to tar the surface before it has been worn into holes or depressions, as it must not be expected that tarring of the surface will convert a bad road into a good one.—[Geo. A. Phillips, A.M.I.C.E., County Surveyor of Glamorgan.]

Taking into consideration the items of utility and cost and the facilities for construction and repair, the author is of opinion that of macadamized roads, one constructed with good stone (water-bound) on a proper foundation, and the surface properly coated with hot coal-gas tar, is the best. The system of tar-spraying roads by machinery has greatly facilitated and reduced in cost what the author considers one of the greatest boons conferred upon the

users of macadamized roads. It lessens wear and tear, prevents damage by suction of pneumatic tires, reduces dust to a minimum, reduces mud, and generally increases the life of the road.—[Henry E. Stilgoe, M.Inst.C.E., Birmingham City Engineer and Surveyor.]

It may be safely said that the best method by which the effect of these dust-creating agents can be counteracted is to make the road waterproof, and the cheapest way to make it waterproof is to tar it. If, therefore, it is possible to lay tarred material at the start, that plan is the best of all. But if not, a coating of tar is the next best thing. The complete removal of dust from our roads is, from an engineering point of view, perfectly practicable, and the only problem now is one of cost.—[The Right Hon. Lord Montagu of Beaulieu.]

Sucking Action of Pneumatic Tires Not Proven.

It is necessary here, therefore, to point out that what is called the "sucking action" of pneumatic tires has never been proved to exist. Certain portions of the Great North Road, which two years ago showed grooves due to the action of the studded tires, since they have been repaired and tar sprayed to a sufficient depth to ensure the tar penetrating ¾-inch from the surface, now at the same places show no sign of grooving. At the same time, I deprecate the use of steel-studded tires. The crushing pressures and the forces of impact of pneumatic-tired wheels are so low that little is gained by increasing their diameter. It is fortunate that this is the case, as increasing the diameter of rubber-tired wheels is a very expensive luxury.—[Col. R. E. Crompton, C.B., R.E., M.I.C.E., M.I.E.E.]

On surfaces which have been treated with tar, or are made of a hard, unyielding material, the motor car wheel causes practically no damage, and it should produce no appreciable wear compared with steel-tired wheels. A steel-studded tire is, however, far more destructive in its effect than an ordinary plain rubber tire. But as long as dangerously skiddy surfaces exist it would be undesirable to absolutely prohibit the use of a metal-studded tire.—[The Right Hon. Lord Montagu of Beaulieu.]

Advocates of Increased Wheel Diameters.

It appears likely that the only practical method of reducing these crushing strains is by increased wheel diameters, and by reducing the axle weight by dividing the load carried or propelled over a greater number of axles.

With modern wheels made of iron or steel, the weight of the wheels for equal rigidity, durability, and strength increases only as the diameter, and I hope that the removal of this error may encourage designers to increase the wheel diameters in future road vehicles.

The question of the springing of road vehicles running at a high rate of speed remained until recently a mystery confined to a few coachbuilders, but, thank to Mr. Lanchester and others, the science of springing, and of the location of the vehicle so as to obtain the best results, has received a great impulse.—[Col. R. E. Crompton, C.B., R.E., M.Inst.C.E., M.Inst.E.E.

There is not the slightest doubt that a light car is the coming vehicle for all purposes, but before the weight of the car can be appreciably reduced, the condition of the roads must be improved. A better road surface will render unnecessary the extra weight called for to resist the shocks of defective roadways. To obtain this and the most economical rolling contact between the wheel and the road, the skill of the two different people concerned is required.—[Sidney H. Chambers, Engineer and Surveyor, Hampton Urban District Council.]

All Users of the Road Should Pay Their Share.

The remedy is not to be found in returning to the exploded system of taxing the actual wheels that pass over the road surface, and the enemies of motors will be well advised not to press this contention too far. If those who use the roads and those who destroy the roads are to pay for them, it may well be found as the result of a scientific inquiry that the tax will fall with overwhelming weight upon the horse-drawn vehicles, which seem now to flatter themselves that they have some exclusive right to destroy the roads uncriticized.—[Earl Russell.]

Necessity for a Central Government Supervisory Department.

It is submitted that these considerations show the absolute necessity for a central government supervisory department, or, perhaps, a specialized branch of the local government board, whose duty would be to inspect the main roads throughout the country and satisfy themselves (a) that those roads are maintained at a proper standard, and (b) that the standard is obtained by the most efficient and economical methods.

Since it appears that the chief defects in the existing system are capable of improvement by comparatively simple means, it is submitted that the county, aided by the purse and inspected on behalf of the government, would form the most convenient and experienced unit for main road administration throughout the country.—[F. H. Berryman, Chairman of the Highways Committee of the Somerset County Council.]

GERMAN STATISTICS NOT ASTOUNDING.

BERLIN, May 20—According to figures up to January 1, 1909, there were the following number of motor vehicles in the German Empire on this date: 39,475 vehicles, used principally for conveyance of persons, among these being 20,928 motorcycles; 9,434 cars of up to 8 horsepower; 5,441 of up to 16 horsepower; 3,595 of 16 to 40 horsepower, and 77 of 40 and more horsepower. There were further 2,252 vehicles principally used for the conveyance of goods; 248 of this number were cycles; 1,035 cars up to 8 horsepower; 502 from 8 to 16 horsepower; 448 from 16 to 40 horsepower, and 19 of 40 horsepower and more.

Of the vehicles used for the conveyance of passengers 395 were in the service of public departments, such as post, army, navy, home, etc., offices; 2,340 were public conveyances (cabs and omnibuses); 16,110 served industrial and commercial ends; 427 were in agricultural usage; 4,641 were used by other professions (medical, land surveying, etc.) and 15,562 for sport and private use, a figure that seems intolerably small to English and American ideas.

The goods vehicles are divided as follows: 143 in the service of public departments; 2,059 for commerce and industry; 24 for agricultural purposes and 26 others not classified.

The Austrian voiturette reliability tour of the Austrian Automobile Club on the Vienna-Trieste-Klagenfurt-Vienna route, May 6 to 9, brought another victory for the Opel cars, as the only one entered and driven by Koch forged ahead early in the event and eventually landed in Vienna far ahead of all competitors. The very difficult first day's run of 500 kilometers knocked several voiturettes out of the competition, but all those that arrived in Trieste held out to the finish. The team prize went to the Austrians, which came in third, fourth and fifth.

AUTO NEWS MADE IN GERMANY.

The guarantee fund for the Frankfort Aeronautic Show has now reached a million marks; a sum of 13,000 marks has been presented by various persons for prizes.

The first speed trial of the Prince Henry Tour will be held on the flat between Guben and Krossen, over a stretch of six kilometers. The road leads through a forest, has hardly any intersecting paths, and no traffic worth mentioning.

The Prussian War Ministry has bought a large territory on the Russian frontier on which to erect a balloon station. The news that Metz is to be the home of one of the Parsevals has aroused much activity in France, and it has been decided to construct two sheds on the other side of the black and white sign posts, one at Nancy and the other at Epinal. The easily aroused Frenchmen are much disturbed over the incident.

The German commercial car trials have come to a successful end at Stuttgart, while the military vehicles will return to Berlin by road. The last stages passed over so quietly that the daily official reports only dealt with the roads taken and the exhibitions at the various industrial centers the cars passed through, and this in spite of the tortuous roads South Germany is so rich in. All through Baden and Durttemberg road men were posted at every wayside stone with pencil and book, the authorities being so much on the alert that they gave rise to a much laughed at incident. At Freiburg a police official was sent out with a bell to cry out the news that the great motor race would pass through the town that morning and parents had best look after their children. The race idea spread by police headquarters at Karlsruhe reached over to Baden-Baden, as at the Oos cross-roads numbers of smart motors were pulled up to watch the "race," and when the heavy monsters came lumbering into view disappointment was rife.

NECESSITY OF STATE GOOD ROADS ASSOCIATIONS

By GEORGE C. DIEHL, Chairman Good Roads Board, American Automobile Association.

THE importance of State good roads associations is not appreciated in the majority of the States throughout the country. This is especially true in the States which have built a great many miles of roads with State aid. In many States the only good roads organizations are those which are composed entirely of the motorists. While the motorists, consistently supported by the Association of Licensed Automobile Manufacturers, the National Association of Automobile Manufacturers and the American Motor Car Manufacturers' Association, do not begrudge the time which they spend in these organizations, they feel that more valuable results could be obtained by having associations representative of not only the motorists, but of the farmers, the county commissioners, county boards of supervisors and the minor highway officials throughout the States.

Such organizations permit the chief highway officials of the State to keep in touch with public sentiment, and disseminate the knowledge gained through the experience of such officials. They also act as a check upon the chief highway officials when inclined to follow unwise counsels. These State associations should meet regularly, and suggest the proper form of new highway laws and desirable amendments to the existing statutes.

These State associations should meet regularly, and suggest the proper form of new highway laws and desirable amendments to the existing statutes.

Two important subjects which State highway associations could properly urge are:

First—The construction of permanent masonry bridges.

Second—The improvement of town or lateral roads.

Bridges—Few of the States aid in the construction of bridges. The entire burden of construction must be borne by the township or local municipality. The result, in sections where bridges are numerous, has been that inferior structures have, owing to lack of funds, been erected. The type usually adopted in such cases has been a light iron or steel superstructure, with plank flooring and railroad-iron pile substructure—or poorly laid rubber abutments. The life of such bridges does not exceed usually thirty or forty years, and if not promptly replaced they constitute a menace to all users of the highway. The usual renewals consist of placing an inferior iron or steel bridge over the old weakened foundation.

The local highway officials not having technical training are frequently misled or corrupted by unscrupulous agents. The bridges constitute an absolutely essential part of the highway and should be erected under State supervision and in part at least at State expense, with the result that in place of weak and inferior structures, solid, attractive and durable concrete bridges will be erected, as an enduring monument to the highway officials in charge of such work.

Concrete Bridges—The cost of erecting a reinforced concrete bridge is little, if any, in excess of the cost of a properly designed steel structure. The cost of repairs and maintenance of concrete bridges is nothing; consequently they endure for ages. Such structures are attractive in appearance, safe at all seasons, pleasing to the eye and eliminate probability of accident.

Town Roads Materials—So much has been said about brick, stone and macadam pavements that the fact that the vast majority of roads must for many generations be dirt roads, is rather lost sight of. By proper care and supervision, under appropriate laws, these roads can be made, for the greater part of the year, almost as satisfactory as hard-surface roads. To show the impossibility of macadamizing all of our roads in one generation, or in any limited period of time, it is sufficient to say that there are over two million miles of roads in the United States; macadamizing costs not less than $5,000 a mile, and usually more than that. At the lesser cost the aggregate expenditure to improve all the roads in the country would be 10 billions of dollars, or a hundred million of dollars a year for 100 years.

The main roads, upon which traffic is heaviest, and which accommodate the greatest population are estimated to be less than 10 per cent. of the whole. The ultimate improvement of these main roads can be reasonably anticipated, if public sentiment is properly aroused.

Improvement of Main Roads—This should not take all the energy and appropriations, but should go forward hand in hand with the improvement of town roads. In some localities for many years the entire amount of highway taxes, whether payable in cash or labor, has been expended in temporary work; while nothing has been spent for permanent improvements, with the result that the condition of the town roads remains unchanged. The roads in some places are no better to-day than they were 50 years ago, notwithstanding the labor and money expended.

There is annually expended on the town or lateral roads of the country $55,000,000 in cash and $20,000,000 in labor. To secure a proper improvement of the town roads it is necessary to abolish the labor tax which is in vogue in about 35 States and to substitute a money tax. It is also necessary to spend a certain amount each year for permanent improvements, in order that each year may see constantly improving road conditions. Many local officials are inexperienced; it is desirable to have the chief highway officials of the States advise and superintend the work done by local officials upon the town roads. Such supervision implies that there should be State aid in cash for town roads.

Under such circumstances it is not difficult to enact fixed rules and regulations which can provide in most cases that not over one-half of the town highway tax shall be expended for highway repairs and maintenance and that the other half shall be used to construct permanent improvements.

Under such a system, in addition to such State and national aid as public sentiment might enforce, there would be expended for permanent betterments about forty millions of dollars annually on the lateral roads through the counties.

The more important lateral roads connecting with the main State roads should be first improved. We must have a steady increase in total mileage of improved roads, main and lateral.

ROAD IMPROVEMENT EVER THE PARAMOUNT ISSUE

By G. VERNOR ROGERS, Secretary American Motor Car Manufacturers' Association.

WITH the coming Spring and renewed touring, the matter of good roads is once more, and more forcibly than ever, a paramount issue with the automobilist, horse owner, the farmer, the pedestrian and, above all, the country school children who have to travel considerable distances from their homes to the district schools. Again has the fact been thrust upon us that the greatest and wealthiest of all governments—the United States—is far behind foreign countries in good road building. The whole country is stirred as never before, relative to this great question of highway improvement. If there is anything in the world that a good citizen who loves his State and that his civic or State pride delights in, it is to have the city and the State reputation maintained.

To-day the finger is pointing as never before to the attitude of the States toward this question; and a State's reputation for enterprise, progress and all that goes to make it worth living in, is determined very largely by the character of its roads—the arteries through which flow the business and pleasure life of a State.

Whenever a farmer loads his wagon he has in mind the worst part of the road over which he has to go, whether that be one or five or six hundred feet long, or has a hundred feet or a hundred miles of good road at each end. He knows that its worst hill or mud hole limits the size of the load he can haul.

Because this is so, every bit of road connecting those on which state money has been spent should be made so good that no mud holes, steep grades, no "worst spots," in short, will be left to limit the wagon-load to less than can be, without difficulty, hauled the entire length of the system of improved roads. There should be no breaks in this chain; no interruption in these great arteries through which flows our industrial life.

The Country Life Commission recently appointed by President Taft, in its report to Congress, makes many interesting statements which, if adhered to, will ultimately result in universally better roads in this country.

The demand for good highways is general among the farmers of the entire United States. Education and good roads are the two things most frequently mentioned by farmers. The Commission in its report says: "We hold that the development of a fully serviceable highway system is a matter of national concern, co-ordinate with the development of water ways and the conservation of our native resources. It is absolutely essential to our internal development. The first thing necessary is to provide expert supervision and direction and to develop a national plan. All the work should be cooperative between the federal government and the states. The question of federal appropriation for highway work in the United States may well be held in abeyance until a national service is provided and tested. We suggest that the United States government establish a highway engineering service, or equivalent organization to be at the call of the states in working out effective and economical highway assistance. That highway improvement is the most important economic reform, has long been urged by the farmers, who, through their principal organization, the National Grange, have been persistently agitating for the adoption of a policy of federal aid for good road construction and maintenance."

The declaration by the Country Life Commission that the establishment of a fully serviceable highway system is a matter of national concern, absolutely essential to our internal development, should serve to hasten the enactment of legislation, provide for the creation of a National Highways Commission, and make liberal appropriations for carrying on its work. This is in full accord with the desires of the American Motor Car Manufacturers' Association which has already contributed a considerable sum of money toward the betterment of good roads in this nearly up-to-date country.

The need for a new kind of country school cannot be met, so long as our dirt roads, which at certain seasons, are almost impassable, prevent the attendance of the farmer's children at centralized schools where they can have all the advantages of a graded school in connection with a high school. Central schools of those kind are now being established in some sections of the country, where good roads permit of the pupils of the entire township being transported to them daily from their homes, and with the extension of improved roads, its school system would become general. In this way, better roads mean much higher education for the country children, a wholesale blessing.

TOURING BECOMES A NATIONAL HABIT

By S. D. WALDON.

AN epidemic of touring is over the land. Largely as the result of the work of the pioneer American manufacturers, constituting the Association of Licensed Automobile Manufacturers, the one-time boulevard autoist now seeks enchantment on the broad country road. He rolls from asphalt to macadam, from macadam to gravel, and from gravel to dirt.

There are now over two hundred thousand motorists in this country. Joyously they take to the wandering ways, among tall shade trees, in the midst of green garbed hills and stone-empaled valleys, or free on the open prairie, in mountain fastness or out on the desert lands.

Many a man who has driven his car around the four corners of his own and neighboring States could not tell you the name of the winner of a Vanderbilt cup race. But these tourists take thousands of roads in scores of kinds of cars and have tens of thousands of stories of pleasant autoing experiences to tell. Collectively, they represent one of the greatest movements for countrifying city-tired denizens.

Individually, the tourist, despite the serious import of the part he plays, if often interesting. He is essentially a modern highly-developed man, taking no part in the spectacular features of autoing. Few accomplishments have created as much general interest as the recent Pacific to Atlantic trip of a business man and his family, five in number.

The intent of many miles of travel does not rob them of their enchantment or of the pleasure afforded by the many shifting scenes. There is always to be encountered a fresh picture; some tourist trying out the roads in a new way.

The road ahead, say, winds recklessly along the crown of a ridge to where the sky, coming down, blue and fluffy, meets the Alleghanies going up, dark and solid. Or the road turns and ends in a wall of underbrush. It comes out of the forest from above, but the connecting link between the path under-wheel and the one sticking out of the trees to the very top of the mountain is lost. So is a moving picture halted by cutting out a strip of the endless film.

Thus the autoists go. Some bold, some timid; some fast, some slow. Every mile of their many pourneys is crowded with incident, like a long story which upwinds, chapter after chapter, always telling something new.

It is all a part of experience, which, multiplying, will dot the landscape with automobiles. Thus we are making a new national habit and yet, we hope, a lot of national pikes. Which is the most beneficial to the country as a whole is hard to say.

MARYLAND MAY EMPLOY CONVICTS ON ROADS

BALTIMORE, May 10—Convict labor will be used in constructing good highways in this State if the efforts of Governor Crothers, backed by the Democratic party, are successful. The chief executive will request the next General Assembly to pass a law making it permissible for prisoners now incarcerated in the Maryland penitentiary in this city, the house of correction, and the county jails to do this work. This is in line with Governor Crothers' economic ideas of roadbuilding. While the last Legislature authorized a loan of $5,000,000 for improved roads in the counties and this city, it now looks as though it will be necessary to ask the next General Assembly to make another appropriation of $6,000,000 to complete the work mapped out by the Good Roads Commission. The Governor believes that the employment of convict labor, together with the revenues to be derived from the proposed tax on automobiles, leases on oyster beds, inheritance taxes, and a probable income tax, will enable the State to satisfactorily meet the interest payments on the present loan and any other loans that may be granted in the future. So is the cause of good roads forwarded all over the country, each State, county and township, in its own individual way, furthering the same end.

Georgia Convicts Cutting Road Through Solid Rock.

Convict Sleeping Wagon Near Lawrenceville, Ga.

GEORGIA NOW SEES THE NECESSITY FOR REAL ROADS

ATLANTA, GA., May 20—Traveling steadily for nearly five days and covering 490 miles in that time, the White Steamer, scouting for the Atlanta *Journal,* rolled back into Atlanta after having threshed out with extreme care some proposed routes for the New York-to-Atlanta endurance test.

This last day's run will presumably cover about 120 miles and will carry the tourists from Greenville, S. C., to Atlanta. Using this run as a basis the scout car worked out with no small difficulty the routes to Atlanta, which are two in number.

The limiting of the number of routes is the result of a typically Southern condition of affairs—a lack of bridges. To go from Greenville to Atlanta the Savannah River must be crossed. And on anything like a direct line between the two towns there are just two ways to cross—by a ferry on the south route and by a bridge on the north.

In threshing out these two ways between Greenville and Atlanta the scout car cruised about for five days, tackling roads of all sorts, from highly polished macadam to lumpy, gullied, rocky, steep side-hills with only faint tracks indicating where a road was supposed to be.

The first day's run was from Atlanta to Lavonia and was without event save that at every town on the route the citizens and city officials—mayors and councils, ordinaries and extraordinaries, sheriffs and convict keepers—turned out to welcome the car and to show cause why the run from New York to Atlanta should come directly through that town. The enthusiasm was in no way short of marvelous. Little towns where perhaps not more than an automobile or two was owned would turn out with the two cars to meet the scout and escort it into the city limits, where there would be a brass band to welcome the delegation and a general outpouring of citizens.

"What do you want done to our roads?" was ever the question, and by taking road commissioners and road builders out in the car and showing them exactly what was needed a lot of great educational work was done. Georgia has convicts on the roads at last and is prepared to do vast amounts of road building. Intelligent directions are now the only things needed.

From Lavonia the car went first to test the Knox Bridge over the Tugalo River. This was found to be in good condition. Then the machine doubled back over another route toward Atlanta, then turned again at Commerce and went straight to Anderson, S. C., where the second night was spent. The Savannah River was crossed at Brown's Ferry.

This ferry is an antiquated bit of machinery—a flat-bottomed craft, just big enough to hold one automobile. At each end of the boat is fastened one end of a long cable. This runs through pulleys fastened on each bank. When the boat is pushed off it is fastened at such an angle that it crosses the stream as a result of the action of the current—after awhile.

A little mathematical calculation shows a bad defect of the route that includes Brown's Ferry. It takes 30 minutes for each round trip and only one car can be carried over at a time. It takes but six hours to run from the west side to Atlanta. Therefore if each car got away immediately after it was ferried across the first car would be in Atlanta when the thirteenth was getting over the river. If there were as many as 30 cars in the run the last one would not be across by dark if the first one started by daylight.

The third day out the car doubled back from Anderson to the river, this time examining the South Carolina side of the route to Knox Bridge and then doubled again and returned to Anderson by another route. From that point the car went straight on to its most northeasterly destination—Greenville.

The return trip was made in two days. On Monday the White ploughed its way over hills and down terrible grades through the shank end of the Blue Ridge, across Jarrett's Bridge and to Gainesville, Ga. Then it had an easy home run.

"Herald" Scout Car Leaves New York

NEW YORK CITY, May 25—To lay out the route of the proposed endurance run from this city to Atlanta, under the auspices of the New York *Herald* and the Atlanta *Journal,* R. H. Johnston and a party in his White steamer started Southward this morning. They expect to travel via Philadelphia, Gettysburg, and Staunton, Va., stopping overnight in each of these places, and will continue South wherever the roads are best. There is an Oldsmobile traveling northward, and when the two meet the Olds will turn and both work towards the southern terminus of the contest. This route is a tentative one, and may be changed if some other itinerary in the South proves more acceptable. With Mr. Johnston were Major John S. Cohen, managing editor of the *Journal;* Nathan Lazarnick, the photographer, and Hamilton Peltz, of the *Herald.*

Georgia's Substantial Auto Enthusiasm

ATLANTA, GA., May 22—At a meeting of business men and automobile enthusiasts at the Atlanta Chamber of Commerce, May 22, $100,000 was subscribed in ten minutes toward the $225,000 necessary to build Atlanta's two-mile auto track. Already land has been purchased near Atlanta and work will be started at once. It is proposed to have the track, grand stand and whole plant finished by November and to have the first race meeting of any importance take place at that time. Thus, a race will be pulled off as quickly as is possible.

Georgia's eight endurance runs to Atlanta in November, all so timed as to bring the cars to the city just before the automobile show, promise to be notable events well worth racing in. Already $5,000 has been hung up in prizes for cars and roads. The scheme was started by the Atlanta *Constitution* and that paper put up $2,500. Other donations have been: Fitzgerald, Ga., $1,000; Savannah *News,* $500; Savannah Automobile Club, $500; Atlanta *Journal,* $1,000.

GLIDDEN PATHFINDER WILL SEEK NEW ROUTE TO OMAHA

THOSE automobilists who expect to participate in the Glidden tour of the A. A. A. this summer have been calling for the most strenuous test yet held, but at the same time they will want roads which are passable. Inasmuch as parts of the route mapped out by Dai H. Lewis, the pathfinder in the E-M-F touring car, were well-nigh bottomless, it has been decided that a different course should be taken. According to directions from Chairman Hower, the E-M-F was shipped last week to Minneapolis after having completed a circuit to Kansas City, and a new direction towards Omaha will be tried. The Iowa gumbo on either side of Fort Dodge, extending northward into Minnesota, was such that ofttimes the pathfinder could hardly move, and this condition must not be when the tourists are on the road. Therefore, it is possible that the car will go directly south from the Twin Cities to Mason City, and diagonally across Iowa, but even the direction remains to be seen. It is not known whether Fort Dodge will be touched or not, although Mr. Lewis says that he does not like to cut off places where he was royally entertained, and where even the farmers went out on the roads ahead of the car, and tried to improve them so that some headway could be made.

After several exciting experiences in southeastern Colorado and in Kansas the car reached the terminus of the route, but under difficulties, for rain, snow, hail, and washouts interfered. The weather in that part of the United States cannot be depended upon, and according to best authorities the fact that roads in the East are better in summer than in winter or spring does not guarantee that such will be the case in Iowa next July. The route which will be examined within the next few days by Lewis will follow a ridge of higher country than the route tentatively selected early in the month. It is also very hilly, and more picturesque on that account, and Mason City is said to have better hotel accommodations for such a large party than has Mankato. The outlining of the route has not been the only matter which has given the authorities concern, for they are constantly being besieged by enthusiastic autoists of the Middle West, who want to entertain the party as it passes through, and who want to have the night stops arranged to occur every few miles. Council Bluffs and Omaha had a very spirited contest, but it is likely that the latter city will be chosen. In Denver the pathfinders were tendered a banquet, which was attended by Governor J. H. Shafroth, Senator T. M. Patterson, Senator John S. Irby representing Mayor Speer, and many officials prominent in State and city affairs. The car was met on the outskirts of the city and a parade of 147 automobiles made up to escort it through the streets.

FROM MAKERS, BUT INTERESTING TO USERS

FRANKLIN ENTRIES IN THE GLIDDEN.

Editor THE AUTOMOBILE:

We are forwarding you herewith a statement showing the position of the Franklin company in regard to the making of a conditional entry of Franklin cars for the Glidden Tour.

H. H. FRANKLIN MFG. CO.

The fact that the entry of four cars for the coming Glidden Tour has been made conditional by the H. H. Franklin Manufacturing Company places emphasis upon the growing effort to secure stricter rules and more rigid enforcement for this event. It specially brings out one matter in connection with the schedule of daily running time.

It is insisted by the makers of the Franklin that if these cars are to participate in the tour the time schedule for the daily runs shall be unalterably fixed before the start of the tour instead of being revised from time to time during the tour at the wish of some one whom those in charge may see fit to listen to. It is urged that a fixed schedule is fair to all and that, on the contrary, it is favoritism to change the running time when weather changes produce road conditions which some of the cars are by reason of their construction much less able to cope with than others. The Franklin company wants all to take conditions as they come, sharing alike and letting the results accentuate the difference in what the several cars are able to do.

The authorities are also called upon to fix in advance of the tour the deterioration rules and leave them unchanged up to the finish, each regulation being given specific interpretation in advance so that there may be no conflict of opinion later. There is determined opposition to the possibility of a committee watching part or all of the actual performance of the cars in the tour before deciding what the relative penalization shall be for the various items of deterioration.

These calls for specific and rigidly enforced rules are a part of effort which has been made to have penalization provided for defects and deterioration of every part of the car, including tires, brakes, carbureters and clutches.

THAT GAETH PENALIZATION IN BALTIMORE RUN.

Editor THE AUTOMOBILE:

We note in connection with your published statement of the Baltimore reliability run, in the miniature tonneau class, that you had the Gaeth penalty consisting of 45 points due to leaky gasoline tank and exhaust pipe.

Our Baltimore agent, F. W. Sandruck, advises that the total penalty was only 12 points, due to the breaking off of rear muffler pipe, and we wish that you would take the opportunity as soon as possible of publishing this correction and stating the fact as above.

We hope you will appreciate the situation, as an incorrect statement in a matter of this sort creates a very bad impression.

THE GAETH AUTOMOBILE COMPANY,
L. E. STONE, Secy. and Treas.

LOZIER GEAR REDUCTION AND DIRECT DRIVE.

Editor THE AUTOMOBILE:

The deduction which you make from the official statistics of the One Gallon Contest in the last number of THE AUTOMOBILE are quite interesting, but we wish to set you right on an assumption you have made regarding the gear used by the writer on the Lozier 6-cylinder car which won first place in the big car class, and third place in the contest—we refer to the following statement, viz.:

"The Lozier figures back to less than 300 engine revolutions if the high gear was used. As this very slow speed of the engine would not be an economical one, it is doubtless true that the driver of this car pinned his faith to a lower gear than the direct drive, figuring that the other economies attendant upon this would offset the transmission losses on the indirect speed."

The official table gives the gear reduction of the Lozier car 2.4 to 1. As a matter of fact, this is the reduction of the fourth speed, but which, as a matter of fact, is an indirect gear, the direct drive to which you refer being the third speed, and which is generally used in touring and in speeding up to fifty-five miles per hour.

The direct or third speed with a gear reduction of 3 to 1 is the gear which was used from start to finish, and this gear was not shifted, except in three or four cases, when the fourth or indirect high gear of 2.4 to 1 was used on level stretches or down hill.

As you state, it would be natural to assume that the slow speed of the engine would not be an economical one, but as a matter of fact, at the average speed of thirteen miles an hour, which was maintained during the run, the speed of the engine varied from 400 to 750 revolutions per minute.

We may be pardoned for stating that the performance is all the more remarkable through this fact, as the official statistics show that the car had the greatest windage, had the highest-powered motor, and carried the largest live weight of any car in the contest.

LOZIER MOTOR COMPANY,
C. A. EMISE.

The amended facts as set forth by Mr. Emise above show that the engine speed figured from the gear reduction of 3 to 1 would be 367 revolutions per minute average, and not 400 to 750, as he states.

This year's international automobile conference takes place June 15 at Vienna, when the Austrian Automobile Club will play the part of host. About thirty delegates are expected, and they will be in time to join in the festivities in honor of the Prince Henry Tour, which is booked for Vienna on this date. Much interest is being aroused as the time draws near.

TWO KINDS OF TRAFFIC THE TROUBLE.

In the recent good roads conference in England a number of points were brought out which were so well taken as to compel attention. One of them dealing with the subject of road surface erosion, as brought about by rapidly passing automobiles, is that the fundamental idea of using the same roads made in the same way for two radically different kinds of traffic, such as the horse-drawn and the self-propelled, is wrong.

The discussion brought out good and sufficient reasons for this as follows: The horse, by means of the caulks on his shoes, loosens the surface into a number of small heaps of material, and the narrow-tired vehicle adds to the wear and tear, which the fast-moving automobile then scatters and carries along. The latter at any rate, and regardless of how it is done, disperses all of the loosened surface material, but does no further damage.

Reasoning from this, the present remedy,—impossible of course,—lies in the segregation of traffic into self-driven and horse-drawn, on roads reserved for each, and built each for its particular service, this being continued until the rapidly decreasing horsed traffic is reduced to a minimum, in which case the road reservation would no longer be necessary.

In the manner set forth, the surface of the horse road would remain in the position in which the horse left it until another vehicle rolled it back into place, with the result that nothing would be lost. So, with the automobile road, the surface would not be cut up into dust for the rotating wheels to distribute over the landscape, because the road being made specially would be oiled or otherwise surfaced for the service which it had to undergo.

* * *

A LESSENED NUMBER OF CYLINDERS?

Following the extreme swing of the power and number of cylinders pendulum of two years ago, toward the maximum and approaching what was once facetiously called "road locomotives," there is something of a tendency to-day toward the other extreme, the backward swing of the pendulum.

This was first apparent in the foreign market. Not only were cab chasses brought out in large numbers powered with the despised (of two years ago) two-cylinder engines, but also numerous private cars of small sizes. Following the lead of the Continental engineers, English makers took up the same trend, but more conservatively. Now, time having shown the wisdom of this policy in the success of the two-cylinder cabs plying in London, the makers of the Isles are about to throw conservatism to the winds and go deep, very deep, into the lowly two-cylinder vertical engine.

And what has been done in this country in the same line? how many cars of this type are to-day to be had in the open market, and what progress in experimentation is being made? This is best answered in figures. There are five American makers putting out engines with less than four vertical cylinders, but of these two are two-cycle and one air-cooled, which reduces the number to two, and both the product of the same engineer.

Seeing, then, that the American maker is apathetic toward this important question, let a few of the real and very apparent advantages be brought out for inspection, taking, for example, the two-cylinder engine. Poor balance mechanically is urged against it, but, in the light of modern progress in and fuller knowledge of the art of balancing, it would appear as if this one prominent disadvantage has been looked at so long that it appears out of all proportion to its importance. It is true that the two-crank two-cylinder engine has an irregular turning effort, but the two-cylinder single crank motor has not, as the explosions occur at regular intervals. With this arrangement, much used on aerial engines, the matter of balance reduces to one of compensating for the extra piston and connecting rod; surely not a difficult task.

There have been a number of reports of cars projected for the season of 1910, and these have included various engines differing from the regular four-cylinder, now general, but not one of those advanced has included the motive power discussed above, namely, the two-cylinder. If old-established houses with fame and prestige like Panhard, De Dion, Renault, C. G. V., and others in France; Adler, Laurin-Clement. Opel, and others in Germany; Siddeley, Napier, Arrol-Johnston, Humber, and more in England; to say nothing of Zust, and cars of similar quality elsewhere, if these firms can build and sell a two-cylinder vertical engine without damaging the reputation of years, but rather enhancing it, what have the American manufacturers to fear in following their lead? Surely here is the chance to capture the medium-priced trade of America's numerically great middle class.

OLD BAY STATE WILL HAVE AUTO MANEUVERS

BOSTON, May 24—When word is received by the Massachusetts military authorities some time between August 14 and 21 that the State of Massachusetts is threatened with invasion by a hostile naval force—the signal for the beginning of the summer military maneuvers—one of the first acts of Adjutant-General Brigham will be to call out the automobile corps that it is proposed to form. And from then on motor vehicles promise to play a most important part in the defense of the Massachusetts coast. According to the plans for the maneuvers only twenty-four hours' notice will be given of the advance of the enemy, which means that the State militia and the United States soldiers quartered in this State will have to work lively in order to protect the long line of coast from Newburyport to the tip end of Cape Cod and to Buzzards Bay, and it is for this work that the automobiles are to be enlisted.

It is proposed to ask the members of one of the crack military organizations, such as the First Corps of Cadets, to supply forty or fifty cars for the eight days of the maneuvers. If the First Corps can supply all the cars that are needed it may be organized as a motor corps and given special work all through the maneuvers. Otherwise a special motor corps will be organized with an experienced motorist and military man at its head. Besides the forty or fifty cars, the military authorities are planning to secure a number of motor trucks and many motor cycles, the former to carry baggage and supplies between the depot at South Framingham and from camp to camp, and the latter to be ridden by dispatch bearers.

One of the first things to be done after notice of the threatened invasion is received will be the placing of signal stations the whole length of the coast, and it is figured that this can be done with the help of automobiles in a few hours. A touring car with seven or eight men and equipment for field telephone and telegraph lines, flag, light and heliograph signalling apparatus, it is estimated, can establish a whole string of signal stations in a very short time and afterward act as supply car for a whole section of the coast. The cars and motor cycles will also be of value in securing and carrying information.

While it is the intention of the authorities to use the automobiles largely in the signal, medical and quartermaster's departments it is not improbable that experiments will be made in the transportation of troops, somewhat after the manner of the recent experiments in England. For instance, if the main body of troops happens to be quartered at a certain point and an attack is threatened several miles away the automobiles will be used to transport the advance guard to the point in danger and to carry as many others as possible in advance of the main movement. The chief military authorities of the State are enthusiastic over the possibilities of automobiles in the maneuvers, and while their use will depend upon the exigencies of the situation, they are outlining some very important work for the motor corps. Individual automobiles probably will be stationed at the different headquarters and will be used by the commanding officers and the umpires, of which Gen. Leonard Wood, U. S. A., commander of Department of the East, will be chief.

Automobiles have been used before by the Massachusetts militia, for in 1905 the White company supplied several steamers for the camp at Westfield. But in previous maneuvers the automobiles have had to do cross-country work and were at a disadvantage. In the coming maneuvers, however, they will be in their proper element, for all along the coast are excellent roads and cars can make the trip from Newburyport to Cape Cod without leaving the macadam except in a few places. No call for automobiles has yet been issued, but it is anticipated that when it is sent out there will be a very general response from owners who are militiamen. The posts will be responsible ones, for the drivers will have to do much outpost work and will always be in danger of capture by a raiding force landed from some of the enemy's ships.

If the automobiles prove as valuable military auxiliaries as is expected it is not unlikely that steps will be taken for the formation of a permanent automobile corps. Owners of cars will be invited to register their machines at the office of the Adjutant-general, with their size, power and carrying capacity, with the understanding that in case of emergency such as a riot, conflagration or the like, the Adjutant-general may call the cars into service and that the State may use them as long as they are needed, reimbursing the owners afterward. The Chelsea fire, a year ago last April, demonstrated the value of automobiles as an aid to the militia, and it is for similar work that the permanent automobile corps is under consideration. General Wood is said to favor such an organization in every State and the Massachusetts military authorities believe in it thoroughly.

GEN. WOOD SUGGESTS ARMY MOTOR CORPS.

NEW YORK CITY, May 24—Major-Gen. Leonard A. Wood, U. S. A., commanding the department of the East, has interested a number of automobilists in a plan for the organization of an army motor corps. It has been suggested that only runabouts be used inasmuch as they would not be called upon to carry troops, but rather for scouting purposes, carrying besides the owner, a soldier or two trained in quick shooting from a moving auto. General Wood proposes to utilize the corps at the regular army maneuvers to be held from August 14 to 21, having the owners of the cars go into camp the same as do the regular troops, although it would not be necessary for them to enlist. The formation is in charge of Henry F. Caldwell, well and favorably known in automobile circles.

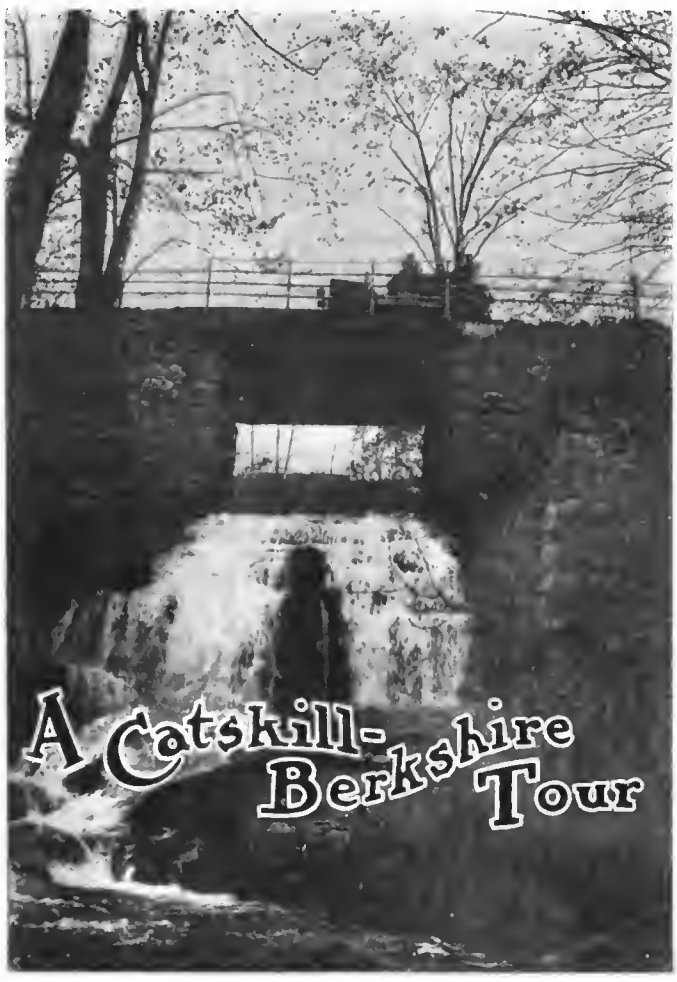
AUTO'S LATEST USE; CHURCH ON WHEELS.

DETROIT, May 24—There is at least one man who does not think the automobile an unmitigated evil, for the Rapid Motor Vehicle Company, of Pontiac, has just shipped to Cincinnati a gospel wagon, equipped with pews, a platform for the speaker and a pipe organ. If anything has been overlooked in fitting up this newest agency for fighting evil it was not discovered. It will be utilized in soul-saving on a trip through the South by "Gipsy" Smith, a well known evangelist.

BANQUET TO REPLACE EUROPE'S BIG RACE.

PARIS, May 22—For lack of an annual road race to unite "Knights of the Steering Wheel," it is proposed that European race drivers should find a common meeting ground around a banqueting table. The idea put forth is that all drivers who have taken part in international road races during the past ten years and have finished among the first ten in any of these events should meet at a race drivers' banquet to be held somewhere in Paris. The idea has met with favor, and the race drivers' banquet will doubtless become an established institution.

Even the French voiturette race, which at one time seemed likely to provide good sport, is now in low water. The regulations have developed a freak type of car with a single-cylinder engine of slightly less than four inches bore and a stroke of ten inches, from which 30 to 35 horsepower can be obtained. Two firms in France, Sizaire-Naudin and Lion-Peugeot, have specialized in this class of diminutive speed monster, with the result that other firms, content to confine their efforts to the production of commercial models, find themselves unable to make even a respectable showing in such company. The consequence is that the voiturette race to be run at Boulogne, on June 20, has only received six engagements, with the possibility of obtaining but three more by the time for closing the lists. The organizers declare that they will hold the race whatever the entries.



This Bridge Separates New York and Connecticut.

PREPARATIONS are going steadily forward for the three-day tour to be held June 12, 13, 14 by the New York Automobile Trade Association. Last week a pathfinding party went over the route in a 30-horsepower White steamer and brought back the report that there is no other three-day trip in the East which can compare in attractiveness with the one selected through the Catskill mountains and the Berkshire Hills. The party, consisting of Chairman Skinner, Photographer Lazarnick, and "Pathfinder" Johnston, besides compiling detailed road directions, made the necessary arrangements with the hotels and garages, and planned the schedule, checking stations, etc., in accordance with the varying road conditions.

The start of the contest will be made from the garage of the Automobile Club of America, in Fifty-fourth street. The cars will then proceed to the West Forty-second street ferry, and, on arriving in Weehawken, "over on the Jersey side," they will check out at one-minute intervals, and will commence to run "on good, old schedule time." The course will follow the Hudson County boulevard for several miles, and then, leaving the shores of the Hudson, will lead into Hackensack by way of the toll road. Arcola is the next town on the route; then comes Waldwick, Allendale, Ramsey, Mahway, with Suffern, the first checking station (28.3 miles from Weehawken). Then will come a ride through the beautiful Ramapo valley, passing through Sloatsburg, Tuxedo, Southfield and Central valley to Highland Mills. Here a detour will be made from the main route to reach the Lake View Hotel, the noon control (48.5 miles from Weehawken). Plenty of time will be allowed for luncheon and arrangements will be made for serving the tourists out of doors, the tables being spread on the shores of the beautiful little lake whose green slopes are surrounded by picturesque hills.

Leaving the noon control, the tourists will continue northward, and on nearing Newburg will once more catch a glimpse of the Hudson. During the rest of the day's trip the route will closely parallel the river, except that, when nearing Kingston, a detour is made inland in order to reach the bridge spanning Rondout creek.

Highland, eighty-two miles from the start, will be the first checking station of the afternoon, and then will come a forty-three-mile run by way of Kingston to the night control, the Hotel Grant, Catskill. The hotel is large enough to accommodate the party without the slightest crowding and an informal dance is scheduled for the evening.

On the second day of the tour, Sunday, June 13, the tourists will have an easy time of it. It has been decided not to start from Catskill until after luncheon, so those in the party will have the morning to themselves. As the contestants will have the use of their cars after checking in at the night controls, some of them will undoubtedly spend the morning in driving to some of the nearby Catskill resorts.

After an early luncheon the tourists will be sent on their way to Albany, thirty-seven miles farther up the river. At Albany the route turns southeasterly and enters the Berkshire Hills. The schedule between Albany and Pittsfield, a distance of thirty-five miles, will be a liberal one, so that all may have an opportunity to enjoy the splendid mountain scenery.

The feature of the afternoon's ride will be the four-mile climb up Lebanon mountain and the long coast down on the other through the quaint Shaker village to Pittsfield. The night control will be at the well-known Hotel Wendell.

The third day of the tour, Monday, June 14, will begin with a trip through one of the most famous resort regions in the world. Leaving Pittsfield, the route leads almost due south, first to Lenox, then to Stockbridge, then through Great Barrington, South Egremont, Salisbury, and Lakeville to Sharon, the first the checking station (46 miles from Pittsfield).

From Sharon the route turns southwesterly through Amenia, Millbrook, and Washington Hollow to Poughkeepsie (77 miles from Pittsfield). After leaving Amenia, the country flattens out considerably, and the run into Poughkeepsie is through comparatively level country.

Poughkeepsie will be the noon control, and the tourists will take luncheon at the Morgan House, in front of which will be the checking station. Located next door to the hotel is "Van's" garage, so that the drivers may readily take on supplies here for the 75-mile run back to New York over the usual touring route. There will be an intermediate checking station at Peekskill (110 miles from Poughkeepsie) and the final checking station of the contest will be in front of the Automobile Club of America clubhouse (150 miles from Pittsfield).

WHAT MASSACHUSETTS LAW MAY BE.

BOSTON, May 24—The Roads and Bridges Committee of the Legislature, which has had before it the uniform automobile bill for more than two months, this week reported the measure to the House of Representatives. It contains the graded-fee provision, cars of less than 20 horsepower to pay $5 a year; from 20 to 30, $10; from 30 to 40, $15; from 40 to 50, $20, and more than 50, $25. A new provision is that a dealer may have five sets of number plates for $25 and must pay $5 for each set in excess of five. The motorcycle fee is $2 and that of commercial vehicles, $5. The maximum speed limit remains at 20 miles an hour, but the limit for thickly settled sections is increased from 12 to 15 miles. The limit at corners, curves, etc., remains at 8 miles. The plan to make the maximum limit 25 miles and driving in excess of that limit conclusive evidence of infraction of the law has been abandoned. A non-resident or his chauffeur may operate in the State ten days without registering.

The bill as reported provides that no person shall allow an automobile to stand in a public way without having the brakes securely and effectively set. If a driver of a horse signals an automobilist must bring his car to a stop and in approaching a street car which has stopped to allow passengers to alight the

car must be slowed down and, if necessary, stopped altogether. Local speed regulations, if made, must have the approval of the highway commission. A deposit of $100 in cash will be accepted instead of a bail bond in cases of arrest for violation of speed regulations. A second conviction of operating while under the influence of liquor is made punishable by imprisonment for not less than one or more than two years. Owners of all public garages are required to keep a record of the movement of all cars so that the same may be at the disposal of the Highway Commission at all times.

SAVANNAH CLUB PLANS FALL RUN.

SAVANNAH, GA., May 24—In connection with the general plan for automobile runs to Atlanta next Fall, previous to the opening there of the national automobile show, the Savannah Automobile Club has decided to arrange an endurance contest to go via Augusta. A cash prize of $1,000 will be given to the winner, half of which will be donated by the club and the other half by the Savannah *News*. It is planned to secure low rates upon automobiles from the North via the steamship lines, so that cars may be sent here and run to Atlanta to the show and return here for the Grand Prize race. The spreading campaign for good roads has been responsible for the action of the enthusiastic autoists of this city.

SOUTHERN CLUB PLANS BIG RACING STUNT.

SAVANNAH, GA., May 24—The Automobile Club of Fitzgerald is deep in the preparations for a big event and its contagious enthusiasm aroused the whole county. At a meeting held last Wednesday, the dates June 15, 16 and 17 were finally decided upon and a committee appointed to look after the advertising and publicity, while other committees to attend to prizes and programs were selected.

RHEIMS WILL HAVE THE AERONAUTS.

PARIS, May 22—Chateauland, after obtaining and losing the French automobile Grand Prix, has been promised and lost its aeroplane race. As soon as it was known that the automobile race would not be held, an effort was made to put an aeronautical carnival on foot. After a considerable amount of work it has to be recognized that this is an impossibility, for the only date available is so close to the Rheims meeting that the Anjou gathering would certainly end in failure. Thus there will only be one great aeronautical demonstration in France this year, on the vast plains outside the Old World city of Rheims. The races begin Sunday, August 22. The Gordon Bennett aeronautical cup will be competed for on the closing day, Sunday, August 29.

AIRSHIPS RUIN LAWNS: A PROBLEM.

LOS ANGELES, CAL., May 24—Residents of this city who are progressive and yet appreciate beautiful lawns are "under" a problem. How to prevent sand, which is used by airships and balloons as ballast, from marring the grass plots, without seeming to rail at progress in aeronautical science, is being seriously considered. Complaints have been made to the chief of police by owners of residences in the vicinity of the city where the Aero Club is holding its flights. It is said that the lawns are being ruined by the sand thrown by the aeronauts in their flights, and the only way of preventing it seems to be under the city ordinance which prohibits the depositing of refuse or rubbish in any place but cans.

Austria's first aeroplane factory has now been called into existence under the assistance of the Austrian Daimler Company and the Austro-American Rubber Company. The capital at present amounts to 300,000 kroners.

Into the Heart of the Picturesque Catskills, Redolent with the Luxuriant Foliage of Spring.

THE MERCER CAR FROM TRENTON, N. J.

TRENTON, N. J., May 24—Newest in automobile trade circles is the Mercer car which is being built by the Mercer Automobile Company. Occupying the former factory of the Walter Automobile Company, the new concern has been organized by local capitalists, with the business and technical affairs guided by experienced automobile men. In two months a car which seems to embody the essentials for a successful career was designed, extensive tests made over the roads, and already six of the autos have been completed with others being prepared. Constructed along lines which are recognized as standard, the cars have motors of 25-horsepower, with the exception of the taxicabs which are given 18-20; selective sliding gear transmissions; and shaft drive. At present the plans call for the production of three models, the chassis of which will be nearly alike. There will be a touring car; a series of roadsters with several body styles; and the taxicab.

The factory has been taken over entirely and 65 men are at work on the Mercer. The first shop order is for 50 machines, and it is stated that the next will be for 500, for agents have already been secured and orders received. The medium price of the car has been an attractive feature.

In the recent endurance run of the local club, through the Delaware valley, a new Mercer was entered and taken right out of the factory for the trip. It made a perfect score and the motor kept running from early morning until evening. The Mercer Speedster, it is said at the plant, will be the type used in contests, and a racing team for the light car events is under consideration.

Papers for the incorporation of the Mercer Company are ready to file. In all probability Charles G. Roebling will be elected president, and J. L. Kuser, secretary and treasurer. The other incorporators are F. W. Roebling, and Col. A. R. Kuser. R. L. Kingston is the general manager, and the designs for the car were made by Mr. Kingston and E. T. Georges.

DUTY ON AUTOS MAY BE INCREASED.

WASHINGTON, D. C., May 24—Automobiles are again in the public eye, and again the Senate has been amused by the tirades of certain of its dignified members, for the duty on autos may be increased. Over an hour was given to the consideration of the part of the tariff relating to "these engines of destruction," and the committee accepted an amendment increasing the customs duty to 50 per cent. on automobiles and automobile parts, leaving the present rate of 45 per cent. on motorcycles, bicycles, and their parts. Senator Heyburn was the principal speaker against the machines, supported by Mr. Hale and Mr. Bailey. Mr. Heyburn, who is from Idaho, a State which recently made large appropriations for building good roads for the ocean to ocean automobile contest, said: "I should like to see a tax of 100 per cent. on these machines, and I am amazed that the courts should have decided that they have the same rights as other vehicles on our country roads. People must flee to places of safety while these engines of destruction pass along the roads. Laugh? Why the rich shout with glee while the farmer flies through the air to be distributed over nearby fences."

ORPHANS' DAY WIDELY REMEMBERED.

Although June 9 has been set by the A. A. A. as the national orphans' day, when clubs, trade associations, or other automobile bodies, would give an outing to the little folks in city charitable homes, a number of cities have found it convenient to select some other dates. A few of those chosen are mentioned here, with the name of the place, and of the body in charge. They are:

New York City, June 9, W. J. Morgan's Voluntary Committee.
Philadelphia, June 9, Quaker City Motor Club.
Brooklyn, N. Y., June 8, Long Island Automobile Club.
Pittsburgh, Pa., June 3, Automobile Club of Pittsburgh.
Cincinnati, O., June 3, Cincinnati Dealers' Association.
Columbus, O., June 19, Columbus Automobile Club.

NEW BOOKS FOR AUTOMOBILISTS.

An Old Friend with a New Name—The fourth edition of the French trade directory "L'Annual 1909," previously known as Baudry de Saunier's Annual, is larger and more complete than its predecessors. Within the stout cloth cover are more than one thousand pages of closely printed matter arranged in alphabetical order for convenient reference. The Annual really comprises two distinct works, the first portion being a list of all firms, persons, clubs, associations, newspapers, etc., in any way connected with the automobile industry. Every French firm and most of the foreign ones have their place in the alphabetical list, the information concerning them being complete and accurate. The second section is a technical dictionary, in which all technical terms are explained by text and drawings in a manner that has not been attempted in any other publication. Persons having any connection with the French automobile industry, or having to deal with French technical terms, will certainly find this work a valuable one to have constantly at hand. The publisher is M. Hubert Baudry, 58 Rue de Monceau, Paris.

Factory Organization and Costs—The recent great interest manifested in these subjects has resulted in the production of this very extensive work on the subject from the able pen of J. Lee Nicholson. Mr. Nicholson is a certified public accountant of New York city, with a large and varied experience in this class of work, consequently he knows whereof he speaks. Although intended primarily as a handbook for manufacturers, it is so arranged and written that it may also be used as a book of reference by the cost accountant, and a textbook for the student. Its 404 large pages are divided into two general parts; first, the subject matter as indicated by the title, under some 39 chapter headings, and, second, mechanical office appliances. The latter is extensively treated in nine chapters, the various machines now on the market being described in detail.

Wage systems are dwelt upon to the extent of 18 pages, while the important subjects of cost accounting, 10 pages, and distribution of indirect expenses, 20 pages, are well and thoroughly covered in the space devoted to them. Distribution, in particular, is worked up in a very comprehensive manner. The balance of the book is devoted to typical forms and their explanation. The work is published by the Kohl Technical Publishing Company, New York City, and as sent out is handsomely bound in three-quarter black morocco.

"Artificial and Natural Flight"—In this small work from the pen of Sir Hiram S. Maxim, one of the first to appear on the subject, there are eight chapters, six of which are devoted closely to the subject, *per se*. Of these chapter four, treating of Screws, touches very briefly upon the screws in use, but confines himself mostly to theory upon which they act. Farman's screws are described and illustrated. The following, or fifth, chapter is an excellent one, treating, as it does, of various experimental work with rotating arms in general, and Professor Langley's in particular.

Amateurs interested in building a machine will refer to the sixth chapter dealing with Building of Flying Machines, in which is to be found a first-rate table of woods; their strengths, weights and comparative efficiencies for aerial use. The closing part of the text matter is a chapter on various subjects, in the last part of which, headed Some Recent Machines, an unwarranted and cowardly attack is made upon the Yankee champions, the Wright Brothers. The sting of the statements is but partly removed by the insertion in the book of a final statement that "recent events show that the Wright Brothers are able to outdo anything that was reported in the American press, etc.," and "the remarkable success of the Wright Brothers has placed the true flying machine in a new category." The book is from the press of the Macmillan Company, 66 Fifth avenue, New York City. The press work is of a high order, the type good and the paper excellent.

Chalmers-Detroit Stranded in Mid Desert.

THE "FLAG-TO-FLAG" DESERT STORY.

Automobilists all over the country read with interest the reports of the experiences of the "Flag-to-Flag" pathfinding party, which was stranded recently in a Mexican desert. The detailed story of the adventures has just been received, as told by W. E. McCarton in the El Paso *Times*. Four men, Mr. McCarton; William Knipper, the driver; F. Ed. Spooner, the photographer; and James Howard, the guide, in a Chalmers-Detroit "30" constituted the outfit, en route from Denver to Mexico City. When the stop came, they were 46 miles from the nearest railroad and 60 miles from El Paso. Mr. McCarton says:

"We left Jaurez on Friday morning, passed Gaudeloupe, and were about to turn around Candaleria Pass shortly after 2 o'clock, when we stuck fast in the deep sand. Our trip all day had been a battle with a terrible sand storm, which drifted like snow, and we seemed to be in an ocean of sand. This district is the worst desert on the North American continent, but notwithstanding the difficulties we made good time until we struck a hidden lake on the mesa, and then we plunged into a depression and were up to the hubs in soft sand. Poles and tackle were of no avail and we started to make the best of conditions. Our water had about given out and all that we had left was some prepared bean soup. We could not get a fire started and when we tried to pitch our tent that was also a failure, because we couldn't drive a stake that would stay. Howard volunteered to go for help, and started out over the pass to look for a ranch house. He was gone over two hours when Spooner and I started out in the same direction, and we met him coming back.

"By 6 o'clock we were getting desperate and Howard and I started west to strike the Mexican Central tracks, while Spooner started back to wait with Knipper. We walked all night over mesa, guided by the north star, and by daylight were completely fagged out, without having seen a sign of habitation. I was all in and by 6.30 could go no further. Howard went on alone and a good many miles further found some water and brought it back to me. We reached the railroad about 2 o'clock that afternoon and caught a train into El Paso. As soon as we recovered and rested a relief party was organized, and went out with food and water for Spooner and Knipper, who had nothing to eat and only the water in the radiator to drink."

JERSEY TRADESMEN HONOR WORKERS.

NEWARK, N. J., May 24—Eulogized as having been mainly responsible for the better automobile legislation now enjoyed in this State, President W. C. Crosby and Joseph H. Wood, of the New Jersey Automobile and Motor Club, were recently presented loving cups by the New Jersey Automobile Trade Association at a dinner given in their honor. In addressing the two guests President George Paddock ascribed to them the services which did most to obtain the new statutes, and expressed for the entire automobile fraternity the gratitude due to them.

NEW PENNSYLVANIA LAW IN FORCE!!!

PITTSBURG, PA., May 24—Just which way an automobilist is to turn in the State of Pennsylvania has been a quandary for several weeks, but Attorney-General Todd has advised the Automobile Club of Pittsburg that the new law is now in effect. This means that tourists from other States, at least those granting reciprocal courtesy to Pennsylvanians, may use Pennsylvania highways for a period of 10 days without taking out a license. The maximum speed is 24 miles per hour. There has been considerable misunderstanding about this matter, and the authorities have given out conflicting statements; but it is believed that the opinion of the State's legal adviser will settle the question.

E. P. CHALFANT TO BECOME A PACKARDITE.

E. P. Chalfant is to transfer his base of operations from New York City to Detroit, whither he will go in about a fortnight to become one of the big cogwheels in the well-planned machinery of the Packard Motor Car Company. Mr. Chalfant's resignation as general manager of the Association of Licensed Automobile Manufacturers will receive attention at the June 2 meeting of the executive committee of that organization. No successor has yet been mentioned, but it is well understood that Mr. Chalfant's occupancy of the place has been very satisfactory to the members.

1910 WHITE STEAMERS WILL USE KEROSENE.

CLEVELAND, May 25—Official announcement has been made by The White Company to the effect that kerosene may be used as fuel on all 1910 models. This is made possible by the fitting of a special kerosene burner, the result of ten years' work on the part of the company. This new burner may be adjusted so as to burn gasoline also, if preferred to the cheaper fuel. The use of kerosene as a fuel will relieve the fast growing scarcity of good gasoline and thus aid to clear up the fuel situation.

PHILADELPHIA HOUSE ADOPTS AUTOMOBILES.

PHILADELPHIA, May 25—Recently the large and old-established firm of Strawbridge & Clothier began a strenuous and protracted test of an Autocar delivery wagon. This test has now been concluded by the purchase of several with bodies of the type shown in the illustration. These are in use for suburban deliveries, which they are enabled to make, not only more expeditiously, but more cheaply as well. Since started on regular service, the cars have not missed a day, nor a trip, and have displaced two two-horse wagons and six with a single horse. In the picture, one of the new self-propelled cars is shown starting out in the morning on its first trip to the suburb with its load of carpets and other things for the suburbanites, whom the management say the cars bring into closer touch with the store.

Autocar Delivery Wagon for Philadelphia Merchants.

BOSTON HAD FIRST Y.M.C.A. SCHOOL.

BOSTON, May 24—The Boston Y. M. C. A. in 1903 established the first automobile school in America. Prior to this time there had been instructions given to a selected few by the garages and factories. Since then the school has continued to prosper and grow in equipment and attendance until now it is acknowledged as one of the foremost schools of automobile construction in the country. It includes not only a high grade of young men who are entering the automobile business as a profession, but also prominent professional and business men who take the course to gain a thorough knowledge of automobiles, not perhaps to drive their own car, but to know whether they are getting maximum results and whether their chauffeur knows his business.

To meet a demand the Boston Y. M. C. A. has established a department devoted entirely to supplying first class automobile help of all kinds to dealers, garages and private owners throughout New England. These men are experienced in driving different cars and in repair work, and have satisfactory recommendations from former employers, but it is only after the investigation of the department that they are pronounced to be of ability and character. The best men, and the ones that are recommended the highest, are graduates of the school who have gone out and received the training of from one to five years' actual road or shop experience.

Another advantage of the department is the elimination of undesirable applicants who are not qualified for the position on account of inexperience or other cause. This is obtained by requiring a statement from the employer as to the requirements of the situation. From this information a man is selected from the list who will fill these requirements.

The department receives the support and recommendation of the largest dealers in Boston, and also their assistance by furnishing experienced chauffeurs whom they can recommend as reliable operators for their particular cars. The department also supplies competent men for the position of helper, or second chauffeur, who are capable of driving and caring for cars under the supervision of an experienced man. This should appeal to automobile owners and dealers in New England, as they are certain of obtaining reliable and competent help without trouble or expense.

BOSTON HOME FOR PACKARD AND CADILLAC.

BOSTON, May 22—Ground was broken in this city to-day for a structure which, when completed next fall, it is believed will be the largest and most complete automobile establishment owned by any dealer in the United States. This is to be the service depot of Alvan T. Fuller, local agent for the Packard and Cadillac, and it will cost, including the land. approximately $200,000. The new building is to be four stories high with a basement and the ground plan will be 70 x 340 feet. The structure will be of reinforced concrete, fireproof throughout. The land, purchased by Mr. Fuller a couple of months ago, is on Commonwealth avenue, corner of Malvern street. It is a conspicuous location and the building will be a prominent landmark on the main thoroughfare leading into and out of Boston from the Western suburbs.

Mr. Fuller will not give up his salesrooms in the Motor Mart in Park square, but will place in the new building a most complete equipment for every kind of work that may be required on the cars he represents. He has long made a specialty of overhauling Packards and Cadillacs and to this work the larger part of the depot will be devoted.

Baltimore, Md.—The new salesroom and garage of the Baltimore-Stoddard-Dayton Motor Car Company, on West Royal avenue, is nearing completion. It will be used exclusively by this company, which handles the Stoddard-Dayton and Renault cars. Leo Schaab is the manager.

DIAMOND TIRES NOT IN AKRON FIRE.

AKRON, O., May 24—It has developed that the Diamond Rubber Company did not lose any tires in the recent fire in this city. The first reports stated that this concern had a large amount of product stored there for shipment, but this was incorrect. The Diamond company had $150,000 worth of fabric in the building, but it was removed a month before the fire.

R. M. OWEN PLACES LARGE CONTRACT.

NEW YORK CITY, May 24—R. M. Owen & Company have placed with the Reo Motor Car Company what is said to be the largest order for automobiles ever contracted for in the history of the industry. The deal involves the marketing of $50,000,000 worth of Reo automobiles by the Owen company. Since the organization of the Reo company, the New York house has sold the product and the plan will be continued.

SEVERE TEST FOR 1910 MITCHELL.

RACINE, WIS., May 24—California has been selected as the testing ground for the 1910 Mitchell car, which has been completed by the Mitchell Motor Car Company. J. W. Bate, the designer of all the Mitchell cars, will ship the new machine to the Pacific coast, and accompanied by General Manager William Mitchell Lewis, will give the car a thorough trying out in the mountains and over desert roads, a varied road condition impossible to be found in the flat country at Racine.

RAPID TRUCK SAVES A TOWN.

CAMPTOWN, PA., May 24—This town owes its existence at present to a rapid freight and passenger truck owned by the Auto Transit Company, which pulled a fire engine from Wyalusing recently to fight a fire that was destroying the town. A most disastrous fire started in a country store and when the alarm was given chauffeur Stone of the Rapid truck started on a record run to the neighboring town for the fire apparatus. Pulling the hook and ladder and carrying twenty-three Wyalusing fire fighters it returned in time to save several buildings which were in imminent danger.

STUDEBAKERS SECURE IMPORTANT CONTRACT.

NEW YORK, May 24—Great significance is attached by those interested in the development and more general use of commercial vehicles to the contract recently executed between the H. C. Piercy Company, of this city, and the Studebaker Brothers Company. By this the former will purchase from the latter an equipment of automobiles which will transform its immense delivery service from a horse-drawn to a mechanically propelled one, and its effect may be realized from the fact that this move will replace the horse delivery service of at least 66 prominent business firms of the city. The Piercy Company's business was started in 1870, and its horses, wagons and men have been organized to a high point of efficiency, directed from a central station, with a substation in Brooklyn. Almost a year has been consumed by the management of the concern in arranging with the engineering department of the Studebaker Company the details of the proposed change, until now it is felt that not the least friction will be noticed in making such a radical alteration and extensive improvement.

The present headquarters are located on West Fifteenth street, consisting of a six-story building containing 90,000 square feet of floor space, sufficient to house 500 automobiles, and with two elevators capable of raising the heaviest ones. The equipment and stable fittings were installed recently with a view to dispensing with them if necessary to make the building a garage. The Brooklyn station will accommodate 50 machines, and it is projected to locate substations in the Bronx and in New Jersey, so that heavy loads may be taken to these points.

NIGHT WORK NEEDED AT SPLITDORF FACTORY.

PRODUCING two hundred magnetos every day, over one thousand spark plugs, and about two hundred coils, the factory of C. F. Splitdorf, in upper New York City, is now in the midst of one of the busiest seasons of its history. Working day and night, closing only on Sundays, it has become the effort of the managament to so arrange manufacturing operations as to fill as much as possible the orders which are received from automoboile factories and retailers all over the country. Having been established in 1858, the Splitdorf laboratory is one of the oldest in the business of making electrical ignition apparatus, and in its comparatively new structure, with its large output, is one of the largest. Six floors and a basement are utilized, and it has been found necessary to make additions on the vacant ground adjoining in order to produce sufficient material to meet the demand. The area of the structure is large in itself, so that there is room for about 600 employees, with the various departments located to economize in space.

Over 150 machine tools are in operation throughout the building; lathes, drill presses and special machines being run at a maximum compatible with producing goods of quality. Everything that goes into the makeup of the apparatus is manufactured by the Splitdorf company; the iron for the magnets is treated, formed and magnetized; the armatures are wound; the magneto parts are machined from the castings; gears are cut; coils entirely formed and packed; and, in fact, every process can be seen from the receipt of the supplying materials to the shipping of the finished products.

On the top floor of the big plant the spark plugs are manufactured, and in their construction are seen some Splitdorf features, such as the winding of mica insulation laterally on the spindle, the claim being that this method is superior to the use of mica disks because it prevents the oil from penetrating to the spindle and short-circuiting. Porcelain is used only as a protector between the top of the metallic bushings and the binding post. A small compression space is designed for the purpose of causing any oil which may get into it to be blown out by the force of the explosion. Of the thousand plugs made, some are of the standard Splitdorf in half-inch, metric, Winton, and A.L.A.M. sizes, and some are low-tension plugs.

The fifth floor is used partly for constructing the coils, several types being made, those for one, two, three, four, and six cylinders, with or without the Splitdorf system of synchronizing and to be used with or without magneto, or for both batteries and magneto. It is stated that about 120 coils for two-cylinder cars are made each day; about ten for four-cylinder cars; about twenty-five for use on marine engines; about ten for the synchronized system, and the remainder for various service. The boxes are all made of mahogany, with the exception of a few made of quartered and polished oak. There are many different styles, for the makers of automobiles want the boxes to fit each individual make of car dash, and for this purpose special sizes and designs have to be followed.

Coil Assembling Room in the Splitdorf Factory.

Two entire floors are given over to the mechanical work in connection with the magneto systems, magnetizing the horseshoe-shaped bars of iron, machining the parts, in assembling the finished sections and in testing the sets. The Splitdorf arrangement gives a unit consisting of the magneto proper and a transformer, the office of the latter being to step-up the voltage from 45 to 31,000. One complete set is made every five minutes.

Splitdorf products consist mainly of six models of magnetos; nearly a dozen types of coils; timers of several kinds; spark plugs, cut-out switches and commutators. The factory office of the concern is in New York City, and branches are maintained in that city, Boston, Detroit, Chicago and San Francisco.

Where Splitdorf Magnetos Are Put Together With Painstaking Care That Every Part Is Right.

The Rambler Doing Duty as a Mountain Climber.

From time immemorial there has been keen rivalry over the honor of climbing McFarland Butte, one of the peaks of Mt. David, near cottage Grove, Oregon. Recently J. B. Van Winkle, of Eugene, Ore., stole a march on his rivals, when he made the ascent with a 34-horsepower Rambler, carrying two passengers besides the driver.

Records Kept of Pierce-Arrow Students—Although the school of instruction at the plant of the Pierce-Arrow Motor Car Company at Buffalo will be continued for some time, a sufficient number of persons have already taken the course to give a good idea of where the chauffeurs come from. An accurate record is easy to keep, since each man is required to give upon a card a notation of his previous experience, both along driving and mechanical lines, as well as his former occupations. The course covers two weeks and then a report upon the capabilities of each student is made. The reports so far show that only 47.3 per cent. of the men have had previous driving experience, and of these a comparatively large proportion have handled Pierce-Arrows, taking the course to refresh their knowledge. Of those who had no driving experience, many had been in lines which did not aid them in the automobiles, 13.8 per cent. having been coachmen who remained with their employers when a change from horses was made. About 14 per cent. were repair men and mechanics. Some of the reports are very interesting, as for instance: "An old coachman. Very willing and anxious to learn, but too old to master mechanical details. However, handles car well and carefully and with practice will develop into a good driver." Another reads: "Bright Irishman, formerly a coachman. Learned rapidly and handles car well. Will develop into very good man."

New Chicago Home for Studebaker—The Studebaker Company is erecting at the corner of Michigan avenue and Twenty-first street what will probably be one of the most elaborate and finely equipped automobile salesrooms and garages in this country. The building will be of solid concrete, seven stories in height, with a frontage on Michigan avenue of 75 feet and 175 feet on Twenty-first street. It is expected that it will be ready for occupancy about January 1, 1910, and as soon as completed the automobile department of the Studebaker Company, now located with the carriage repository on Wabash avenue, will take possession of the entire building. With three factories—the Studebaker-Garford, at Elyria, building 1,500 cars every year; the Studebaker E-M-F plant in Detroit, turning out 1,000 medium-priced cars every month, and the South Bend factory, making over 1,000 electric pleasure and commercial cars a year—the Studebaker will make the same bid for position in the automobile field as it has in the carriage business.

Prizes for Pictures of Rambler Autos—Thomas B. Jeffery & Company, Kenosha, Wis., the manufacturer of Rambler automobiles, has just awarded $100 in cash for photographs illustrating the pleasure and utility of owning a Rambler car. The offer was made some time ago through the house organ, the Rambler magazine, and as there are 15,000 owners of Rambler cars in this country, according to the factory officials, it was but a short time until several hundred photographs were received. The prize winners are as follows: Rambler Garage & Supply Company, Norfolk, Va.; W. K. Cowan, Los Angeles, Cal.; P. W. Lochmiller, Albion, Neb.; H. W. Brown, Tifton, Ga.; J. H. Linsley, New Haven, Conn.; H. W. Davidson, Marietta, O.; C. M. Willis, Auburn, Cal.; M. H. McCarthy, Somerville, Mass.; Arthur Cumings, Winthrop, Mass., and John S. Butzer, Ephrata, Pa.

Waverley Makes Hard Cross-Country Run—In delivering a Waverley electric auto recently the E. Keeler Company, of Williamsport, Pa., was required to give the machine an unusually critical test. It was to be taken to Milton, 31 miles away, and in that distance the roads were none too good and there were seven hills to be climbed, some known to have inclines as steep as 20 per cent. Manager A. A. Maitland directed the test, the car being driven by Harry Knoll, and accompanied by Elmer Shrimer, the purchaser. The distance was covered in two hours and twenty-five minutes' running time, without any trouble or endeavor to make a fast trip.

Oldfield Will Use National "Six"—Barney Oldfield has announced that this year he will outline an active campaign for racing on straight-away courses as well as on the track, and says that it is his intention to drive his own car without any connection with the makers. He has recently ordered a six-cylinder National and is in Indianapolis at present superintending its construction. It will be a stock model, except that the chassis will be somewhat lighter than the one used at Savannah and in the New York Carnival races and hill climb.

Manufacturers of Lubricants Meet—The committee of manufacturers of lubricants of the Motor and Accessory Manufacturers' Association met recently and formally organized. George Baum, of Adam Cook's Sons, was elected chairman and W. M. Sweet, of the association, temporary secretary. The members present were: William B. Shedden, the Columbia Lubricants Company, of New York; L. H. Snyder, the Jos. Dixon Crucible Company, and George Baum, Adam Cook's Sons.

Turner Brass Works Secures Injunction—The Turner Brass Works of Sycamore, Ill., manufacturers of mechanical appliances, automobile specialties, etc., has secured a permanent injunction restraining the Appliance Manufacturing Company, of Chicago, from manufacturing or selling the Amco bumper. The Turner Brass Works is the licensee of the Harroun bumper patent, No. 873,544, upon which its litigation was maintained.

Swinehart Tire Company Will Not Move—It was reported recently that the Swinehart Clincher Tire & Rubber Company, of Akron, O., was about to consolidate with the Mansfield Rubber Company and would move to Mansfield, O. B. C. Swinehart, vice-president of the Swinehart Company, announces that this report is incorrect and that his concern has no idea of either consolidating with any company or of leaving Akron.

New Concern to Make Supplementary Springs—M. H. Cormack, of New York City, has organized and incorporated the firm of H. H. Cormack & Company, of which he is president. The concern will manufacture a line of supplementary spiral springs, together with several other lines of automobile accessories.

Auto Factory for Oklahoma City—J. B. Worthington & Company has purchased machinery to be used in an automobile factory in Oklahoma City, Okla. It has already been shipped to the Southwest and as soon as it can be installed will turn out completed cars.

Bosch Magneto on Flag to Flag Car—The Bosch Magneto Company is calling attention to the fact that the Chalmers-Detroit car which is blazing the way for an endurance run from Denver to Mexico City is equipped with a Bosch magneto.

IN AND ABOUT THE AGENCIES.

Haynes, Philadelphia—The Haynes Automobile Company, of Pennsylvania, which will handle the Haynes output in Philadelphia and adjacent territory, has opened handsome salesrooms at 211-213 North Broad street. James H. Johnson & Sons will manage the new concern.

Herreshoff, Philadelphia—To round out its line, which at present consists of the American, Midland and Babcock electric cars, the Stoyle-Vogel Company, at the southeast corner of Broad and Race streets, has just secured the local agency for the Herreshoff car.

Reo, Savannah, Ga.—Charles P. Henderson & Company, general Southern agents for the Reo Motor Car Company, have opened new offices and salesrooms at 119 State West, to be occupied until their new building is completed.

RECENT BUSINESS CHANGES.

Pittsburg Truck Company Will Move—Having secured a factory at Ithaca, N. Y., the Pittsburgh Motor Truck Company will move from the Smoky City to the town of Koppel, N. Y., and take its Ithaca plant to that place. The concern has been recently chartered with a capital of $100,000 and will engage in the manufacture of automobile trucks.

Slack Mfg. Company, Springfield, Vt.—W. W. Slack, president, Gilman & Son, Inc.; H. K. Parkman, secretary, Gilman & Son, Inc., Springfield, Vt., and G. C. Parker, sales manager, Wm. J. Smith Company, New Haven, Conn., have formed a partnership for the purpose of manufacturing and selling Abrasive Metal Cutters, under the name of Slack Manufacturing Company, Springfield, Vt., all parties to retain their present positions with their respective companies.

John Kane Mills has announced his withdrawal from the firm of Mills & Moore, of New York City, the managers of the New York to Seattle endurance and other contests, and familiarly known to the trade as "accelerators of sentiment." Private business matters requiring his undivided attention at present are responsible for the move, according to Mr. Mills.

A. E. Schaaf will be the general manager of the American Fiat factory, which will be located at Poughkeepsie, N. Y. Mr. Schaaf was formerly general manager of the Pope Motor Car Company, of Toledo, and with Mrs. Schaaf is now taking a tour from Paris to Turin, the home of the Fiat, with Nazarro at the wheel.

J. Howard Morse and Mrs. Morse, of Hartford, Conn., have sailed for Europe to spend the next three or four years in touring upon the Continent. They will make their home in Switzerland. Mr. Morse was formerly president of the Automobile Club of Hartford.

Alfred Reeves, general manager of the A. M. C. M. A., has just returned from a trip to the various automobile factories in Pennsylvania and states that from the indications the Keystone State is now taking a lead in the automobile industry.

Hiram Percy Maxim, designer of the Maxim-Goodridge electric automobile and the Maxim tire inflater, has sailed for Europe to demonstrate his gun silencer. He will go to London, Liege, Paris, Berlin and Vienna.

F. A. Barker has accepted a position with the Overland Automobile Company of Indianapolis, Ind. He was formerly publicity manager of the Dayton Motor Car Company, of Dayton, O.

J. E. Finney has joined the sales forces of the Savannah, Ga., agent for the Reo automobiles. He was formerly connected with the Buick agency.

Wilbur C. Walker, secretary of the Pope Manufacturing Company, has returned to the factory from a business trip to the Pacific Coast.

NEW AGENCIES ESTABLISHED

Maxwell: Pasadena, Cal.—Maxwell Automobile Company, F. J. Purdy, sales manager, 161 West Colorado street.

Durocar: San Francisco, Cal.—W. A. Breen and J. A. Houlihan, Golden Gate avenue and Polk street.

Rider-Lewis: Minneapolis, Minn.—Segerstrom Automobile Company.

Rider-Lewis: Macon, Ga.—Napier Auto & Supply Company.

Gaeth: Milwaukee, Wis.—Auburn Motor Garage Company.

Rider-Lewis: Dallas, Tex.—White Sales & Garage Company.

Regal: Springfield, O.—E. D. Valentine, King Garage.

Rambler: Springfield, Ill.—Springfield Garage Company.

Gaeth: Chicago.—International Automobile Company.

Auburn: Orange, N. J.—J. J. Mayer, for the State.

Rider-Lewis: Iowa—J. A. Wicke, Marengo, Iowa.

Frontenac: Baltimore, Md.—Meredith Dryden.

E-M-F: Arcadia, Fla.—Major W. G. Welles.

Frontenac: Passaic, N. J.—E. J. Beuret.

Brush: Bloomsbury, N. J.—James T. Smith.

Ford: Opelika, Ala.—G. R. Spencer.

RECENT INCORPORATIONS.

Livingston Radiator & Manufacturing Company, New York.—Capital $100,000. To manufacture cooling and heating radiators, automobile engines, cars, wagons, boats, aeroplanes, etc. Incorporators: J. N. Boyle, A. S. Rockwood, Thomas Roberts, 30 Broad street.

Belmont Automobile Manufacturing Company, New Rochelle, N. Y.—Capital $100,000. To manufacture, rent, and sell automobiles. Incorporators: Douglass Hamilton, H. A. Melser, H. A. Lucker.

Fred J. Titus Company, Newark, N. J.—Capital $100,000. To manufacture and deal in automobiles, aeroplanes, airships, etc. Incorporators: Fred J. Titus, John N. Hance, Grace D. Hance.

Pittsburgh Motor Truck Company, Wilmington, Del.—Capital $100,000. Incorporators: P. C. Benedict, Salamanca, N. Y.; C. C. Conkle, Pittsburgh, Pa.; M. E. Smith, Wilmington, Del.

Belmont Automobile Company, New Rochelle, N. Y.—Capital $100,000. To manufacture, rent and sell automobiles. Incorporators: H. A. Melser, H. A. Lucker, Douglass Hamilton.

Taxi Garage Company, Augusta, Me.—Capital $200,000. To carry on a general cab and truck business by motor or other power. President, R. S. Buzzell; treasurer, S. W. Pike.

Times Auto Supply Company, New York.—Capital $20,000. To manufacture automobiles, motors, motor boats, etc. Incorporators: C. O. Jones, B. H. Ellis, H. T. Johnson.

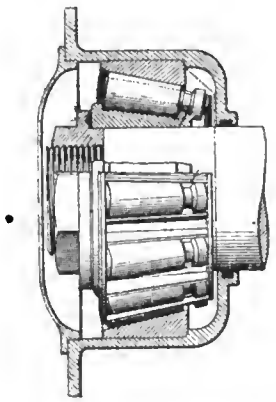
The Governor's Trophy.

This is the handsome cup put up by the Keystone State's chief executive for the Harlsburg run, and won by a 28-horsepower Franklin machine, Carris driving.

SOME SELECTED AUTO PATENTS

Issue of May 18.

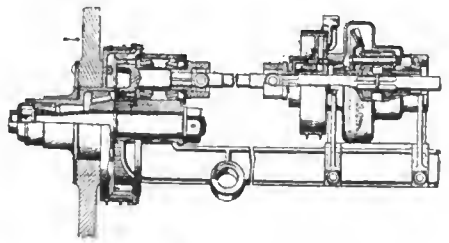
921,656. Roller Bearing. Herbert W. Alden, Canton, Ohio. Filed April 15, 1907.



Alden Roller Bearing.

The feature of this invention of the well-known Timken engineer is the pressed steel cage which retains the rollers in place. While pressed steel cages have been used by the Timken people for some time, this one is constructed in a decidedly different manner. The rollers are retained by flanges and not by holes.

922,372. Propelling Mechanism for Motor-Driven Vehicles. Alexander Winton and Harold B. Anderson, Cleveland, Ohio. Filed Oct. 30, 1906.



Winton Rear Axle Construction.

As the apparent handwriting on the wall, this looks like a new idea in Winton rear axles, along the same lines as that used in the De Luxe. The rear bevel and differential housing are carried above the rear axle proper, which has an I-section. From the driving shaft to the rear wheels, the drive is not direct but is by means of spur gears, housed within the rear hubs and brake drums combined.

921,679. Controlling the Exhaust from Internal-Combustion Engines. Thomas B. Doolittle, Branford, Conn. Filed Aug. 27, 1908.

921,705. Timing Gear Mechanism for Explosive Engines. Lindley D. Hubbell, Hartford, Conn. Filed April 27, 1908.

921,710. Pneumatic Tire. Grant Jacobs, Des Moines, Iowa. Filed March 13, 1908.

921,754. Transmission-Gearing. John M. Van Dyke and Fayette R. Rowell, Canastota, N. Y. Filed Sept. 8, 1908.

921,769. Starting Device for Gasoline-Engines. John L. White and Joseph B. Polo, Clear Lake, S. D. Filed Feb. 8, 1908.

921,802. Rotary Explosive-Engine. Schuyler H. Conkey, Minneapolis, Minn. Filed July 30, 1908.

921,862. Vehicle-Spring. Edmon F. Mayhew, Mooresville, N. C. Filed Nov. 11, 1908.

921,864. Valve-Motion for Gas-Motors. Gustav Mees, Dusseldorf, Germany. Filed Oct. 21, 1903.

Some Recent Trade Publications

Herz & Company, New York—Ignition specialties for automobile, marine, and railroad gasoline engines, manufactured by Herz & Co., New York and Vienna, are listed in the new catalogue of this concern, entitling it an edition for 1910. The Herz timers, with roller and wipe contacts, the new steel-shoed contact, and various other designs are taken up in detail, not only giving the prices of the completed devices, but also illustrating and rating every part. This feature alone would make the booklet especially valuable to designers and engineers, as well as to owners and supply dealers. The distributor, coils, and Herz Bougie Mercedes spark plugs are described at length, as are also the Herz importations of ignition cables and wires, battery connections and terminals, switches and copper-asbestos gaskets. The Herz Company is making a specialty of its air pumps for use in inflating tires, in self-starting devices, for whistles on boats, and many other places where compressed air is needed. Two types are driven by friction from the flywheel or other moving part, one of which is kept in contact with the driving part by a spring, and is bolted to the frame or some other convenient member, while the other is held against the revolving wheel or shaft by a handle, and is portable. In both of these the pistons and cylinders are of gray cast iron, with piston rings of the same material, no leather being used. Between the pump driving friction wheels and the pistons are sets of speed reducing gears. Each pump is tested at 120 pounds pressure, and will run at high speed, so that the largest tire can be quickly inflated. The motor boat outfit includes a tank and whistle, and safety valve. The pump with the handle can be taken to any part of the auto or boat and when not in use, the handle can be removed and the entire device packed in a small space. Two mechanically-driven pumps are also catalogued and described. Herz magnetos and the Paternoster shock absorbers are taken up in detail, with instructions as to their application and maintenance.

American Locomotive Company, New York—Alco gasoline automobiles, now licensed under the Selden patents, are ably described in a handsome catalogue just issued by the makers, the American Locomotive Company of New York and Chicago. These cars are the successors of the American Berliet, and continue in their construction the finesse of details and ability that characterized the Americanized French product. On heavy calendered paper, with clear and comprehensive cuts and text, the new edition of the Alco book is one of the finest seen, in regard to the 1909 automobiles. Detail illustrations give an idea of the type of the cars produced, a four-cylinder and a six-cylinder chassis being shown, the latter from above. Separate cuts of the two engines, transmission with its double bevel drive employing direct drive on both third and fourth speeds, transmission dissembled, multiple disc clutch, rear wheel assembly, are given. The body designs are shown by four illustrations of completed cars, two for touring and two enclosed. A rear view and details of the tonneau and front seat with control system are added. The text is of more interest to the casual reader than is often found in such booklets, giving the details of construction in a very pleasing and instructive manner, and at the same time convincingly showing the advantages of the types adopted for the Alco cars. Features are given as sturdiness, balance, anti-fatigue metal, and long life. Inasmuch as the 40 and 60-horsepower cars are the leaders in the line they are treated in greater length than is the 32-horsepower model, such as is used in the town cars and taxicabs, although frequent reference is made to the latter when its style is especially similar to that of the larger ones.

Locomobile Company of America, Bridgeport, Conn.—The latest publication of the Locomobile Company deals with the 1909 product. This is the eleventh annual catalogue and describes the new shaft drive and other models. Following a few pages of general text comes a very complete description of the mechanical details. These are not general and vague, but specific and to the point. Besides the subject matter, dealing with the parts, the illustrations, about evenly divided as to photos and line-cuts, are very well selected. The scope of this treatment may be judged from the bare statement that almost four full pages, 9 by 12 in size, are devoted to the engine. The new shaft drive construction is elaborated upon to the extent of three pages. As this illustrates a new principle, and one that is worthy of study, the space is well used for that purpose. In this design all torsional stresses have been removed from the rear axle. The result is a stronger construction and one that rides easier. Naturally it is also productive of longer life, a point worth considering when purchasing. An interesting portion of the rear end of the book deals with the Fairmount Park races in Philadelphia during Founders Week. The road race at that time was won by the Locomobile entry, and a series of excellent pictures of the race are given. Some space is devoted to the Vanderbilt Cup race, also won by Locomobile.

Jewell Motor Car Company, Massillon, O.—Descriptive of the 1909 models of Jewell automobiles, the new catalogue is a beautifully compiled book of 32 pages, dealing with the entire construction of the regular 40-horsepower touring cars, limousine and roadster, and the Jewell-Keeton city and suburban car. The photographs and general make-up of the catalogue is in keeping with the "beauty and elegance of finish" which it attributes to the product of the concern. This is the third year of Jewell 40's, and little change has been made in the power plant and operating parts. The 1909 touring car is built with extra seats, making its capacity seven; the roadster can be equipped with either single or double rumble or bucket seats, and the limousine is designed to compare favorably with the finest output of other concerns. The engine, transmission, clutch, axles and other appliances are illustrated and explained in the book. The Jewell-Keeton car is one built along European lines, with thermo-syphon cooling, the radiator back of the engine forming a part of the dash, fixed spark advance and developing 24-30 horsepower.

S. F. Bowser & Company, Inc., Ft. Wayne, Ind.—Gasoline storage outfits of numerous sizes and types, lubricating oil wells, etc., are well described and illustrated in a catalogue received from S. F. Bowser & Company. From an illustration on the cover, which is said to be drawn "to arrest the attention" of a reader to the ten reasons for the installation of Bowser outfits, the book is of interest. Garage proprietors, owners of private garages, and prospective builders will find the booklet of extra use. A great many cities require that the gasoline shall be kept under ground, and where this is not so, the fact of economy in space and gasoline itself are commendable reasons for the use of such systems. Five distinct sets are illustrated and described in the Bowser book, any of which can be employed to store gasoline or kerosene, or both in separate tanks. Three types of oil tanks are mentioned, and an illustration given of an outfit in a private garage where the gasoline, kerosene, and two grades of lubricating oil are kept out of sight, and only the pumps enter the building.

Barrett Manufacturing Company—An attractive catalogue dealing with Tarvia for roads has been issued by the Barrett Manufacturing Company, beautifully illustrated with scenes from several parts of the country. The book is entitled "How to Construct and Preserve Macadam Roads and Prevent Dust," considering in turn the action of automobiles upon roads and the need for some better surfacing material, the endorsement of the tar treatment, and then Tarvia "A," "B," and "X." Experiences of prominent road engineers and supervisors are cited, and letters from a number are included. The photographs of roads treated with Tarvia products are highly interesting, not only from the standpoint of the Barrett interests, but also for their scenery. They have been well chosen from the possible many, giving views of good Pennsylvania roads in the suburbs of Philadelphia, those in the outskirts of Boston, in New Jersey, Iowa, Nebraska, and many other places.

Diamond Rubber Company, Akron, O.—"Ten Years in the Ascendency" is the title given to the sixth edition of the Diamond tire book just issued. The booklet combines the features of a catalogue with a source of much valued information upon tires in general and Diamonds in particular. It is strikingly bound in blue, with a copy of the engraving which caused so much favorable comment during the shows, when used as a Diamond advertisement, that of the title on the cover. The typography is excellent and the cuts distinct in order to illustrate the features of treads and rims. Various types of Diamond tires are discussed, wrapped tread, non-skid, Bailey tread, and tubes; and of rims there are several—standard clincher, Fisk bolted-on, Marsh, and demountable, with instructions for changing tires. A set of "don'ts" and of "do's" is of interest to the owner of an automobile. This feature makes the book one of instruction and additional value.

New York & New Jersey Lubricant Company, New York—"A Cylinder Oil with a Pedigree" is the title of an attractive little booklet issued by the New York & New Jersey Lubricant Company on its new cylinder lubricant, "MoToRoL." The presentation of the cylinder oil subject assumes a new tone in this "MoToRoL" booklet, and the printing embellishments are unique. Basing argument on the fact that too often cylinder oil is selected at haphazard, or on the strength of some popular fallacy, the suggestion is offered that the reputation of the manufacturer is a safer basis for choosing a lubricant. "Non-Fluid" oils for the lubrication of transmissions and bearings in automobiles are well known, and their adoption by many automobile manufacturers is offered as warranty for confidence in the new production. The booklet states that "MoToRoL" is as effective for cylinders as "Non-Fluid" oils for transmissions.

Joseph Dixon Crucible Company, Jersey City, N. J.—What might be called a pocket edition general catalogue has been issued by the Joseph Dixon Crucible Company. This lists the principal products, such as crucibles, facings, lubricating graphite, greases, pencils, protective paints, etc., giving brief descriptions and prices. It is of value to the purchasing agent, engineer, contractor, superintendent, and anyone who uses or specifies graphite in any form. The booklet is of commercial envelope size, and will conveniently go in the pocket or desk pigeonhole. It is substantially bound in tough cover stock, and attractively printed. Copies may be obtained from the Dixon Company.

Schacht Manufacturing Company, Cincinnati—A book recently published by this house gives a number of good pointers on the kind of an automobile to buy so as to get the greatest amount of satisfaction. A few of the subjects covered are trips to town, markets, neighbors, doctor, saving one-third of your time, healthful recreation, low first cost, run on less cost that feed for horses, always in the barn, ready day or night, get you there and back again. Just send your name and the manufacturers will send you this book free. The address is the Schacht Manufacturing Company, 2721 Spring Grove avenue, Cincinnati.

Morrison-Ricker Company, Grinnell, Iowa—The Morrison-Ricker Manufacturing Company of Grinnell, Iowa, has issued a new catalogue of its complete line of automobile gloves. The cover design is unique, artistic, and original; the colors striking and attractive. Everyone interested in auto gloves, whether dealers or wearers, are invited to send for a copy. "A glove to suit every requirement, every taste, and every season," is the announced aim of the manufacturers of Grinnell gloves.

General Automobile Supply Company, New York—J. C. Nichols, president of the General Automobile Supply Company, Inc., has issued the 1909 catalogue of automobile accessories and supplies. In it are described and listed almost anything an automobilist can think of with which to equip his car. Lamps, speedometers, coils, magnetos, oilers, oil cans, pumps, oils and greases, tires, tools, etc., are all mentioned with the General Company's rates. A mail order business is being carried on.

The Waverley Company, Indianapolis, Ind.—Bridge whist and Waverley electric automobiles are united in the latest publication of the Waverley Company. This is a bridge whist score book, and on each page is a cut of one type of Waverley with some hints on playing the game, and then as applied to the operation of the cars, from the opening lead to the return triumphant. These score books may be had upon application.

Information for Auto Users

Hill Folding Seat—As the demand for large cars of roomy capacity continues there is an equally strong demand for a suitable folding seat for the tonneau by owners who do not have the additional seats, although their cars are large enough for them. This great demand has induced a number of coach and body builders to bring out a seat for this purpose. Chief among these the product of the Hill Manufacturing Company, Buffalo, N. Y., is remarkable for its simple construction and the ability to fold to a very small size. The back folds down onto the seat, which then turns up into a plane at right angles to the floor of the tonneau. More than this, the whole folded seat may be swung around

READY FOR USE. FOLDED UP.
HILL FOLDING TONNEAU SEAT.

so that it comes still closer to the sides. The application is very easy, consisting of fastening two blocks, one to the floor and one to the side frame, so as to form an exact right angle. To these two blocks the attachment requires but seven screws. The seat is trimmed in genuine machine-buffed leather over spring cushions. The form is that of a circle, 13 inches in diameter. The folding back is 17 inches high. The picture shows, besides the seat open and folded, an extra set of seat attaching irons.

Oilzum Automobile Oils—Of all the different petroleum produced the world over, the purity of a home product is the best. This is the Pennsylvania patroleum which is, on account of its purity, more expensive than other less pure products. In the production of a high-grade cylinder oil, the White & Bagley Company, Worcester, Mass., manufacturers of Oilzum cylinder oil, found that this was the only product pure enough for their use, despite the price. This use results in a pure mineral oil, containing no animal or vegetable matter, both of which are liable to decomposition and the formation of destructive acids, the effect of these upon cylinder walls being self-evident. One very desirable point in connection with the subject of lubrication, is a high flash point, and what usually goes with it, a high fire test. As might be expected from the resultant of high-class raw material, and a high-grade process. Oilzum possesses both of these requisites.

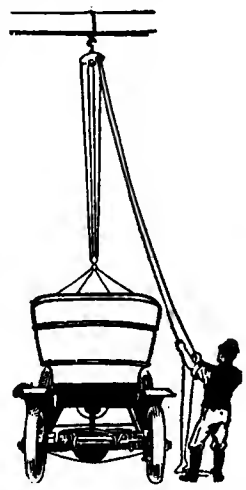
Ordinary oils contain some carbon; in some this has been concealed by bleaching with acids; the best and most trustworthy way is by continuous filtration. This method is very costly but the resulting oil is good and worthy of the very best use, such as for cylinders. It is interesting to note that filtration is the only method which has ever been used in the preparation of Oilzum oils. This filtration sounds simple, but in practice it means passing the oil through graded Fuller's earth, not once nor twice, but times without number, at least up to a dozen or twenty.

Auto Type Ampere Meter—One of the greatest drawbacks of the storage cell for ignition purposes is the necessity for charging at frequent intervals. This is liable to come at a time when the use of the car is particularly to be desired, and any device which would prevent that from happening would go far toward increasing the popularity of the storage battery. A little meter just put on the market by the Sangamo Electric Company, Springfield, Ill., will go far in this direction. This is a small enough device to allow of its use on the dashboard. so that any one may attach it, after which the very beneficial use for which it is intended would be self-evident. It is also made in sizes sufficient for use with electric vehicles, for which it was brought out primarily. With one of these meters on the car it is impossible to get stuck out on the road, with the consequent chagrin attendant upon being towed home.

SANGAMO AMPERE HOUR ELECTRIC METER.

The illustration shows the meter with the cover removed, displaying the mechanism. The cover is simply a square box of metal, which fits rather closely over the mechanical parts, being held on by the two studs shown projecting from the back of the frame. The one shown is for a 60-ampere hour battery, but they may be had for any capacity.

Burr Self-Locking Block—One of the handiest things around a garage, using any form of block and tackle to lift cars or other heavy objects, is the Burr automatic safety tackle block, made by the Burr Manufacturing Company, Cleveland, O. This has a locking device, which comes into play as soon as a load is placed upon it, thus allowing of hoisting a car or weight off of the floor and leaving it suspended, without tying the rope or resorting to other and similar questionable means of fastening it. This distinctive Burr mechanism lets a person use the simple, cheap, and easily obtained hemp rope, instead of the more expensive steel cable. The Burr safety lift is made of the best selected steel, and has no teeth, wedges, eccentrics or springs to get out of order. Moreover, it works under any and all conditions, on wet or greasy rope, and at any angle, even when inverted.



BURR AUTOMATIC BLOCK

The probable greatest field of usefulness for this block lies in the private garage, where the expensive chain block or more expensive duplex hoist represent an expense out of all proportion to the rest of the outfit. Yet a hoist of some sort is a real necessity, so that the safety lift will find a niche into which it will fit very nicely midway between the plain rope hoist, with very apparent disadvantages, and the expense of the more mechanical devices.

Elba Lighting Battery—There is at present a strong tendency toward the use of electric lights for automobiles and motor boats, and this tendency is being given proper support by the ignition specialists by the production of a battery especially designed and built for lighting work. The convenience and cleanliness of this method is daily attracting more recruits and these should take warning that it is possible to overload a battery on a lighting circuit. The Willard Storage Battery Company, Cleveland, O., are among the first to bring out a lighting battery for lighting purposes, the Elba. While this resembles in external appearance the ordinary storage battery, its internal construction is such as to allow discharge at a much higher rate than is the usual case, and without injury. The Elba battery is rated at the regular Pullman car lighting rate.

ELBA BATTERY FOR ELECTRIC LIGHTING.

Climbing "Giant's Despair" No Longer a Real Task

By A. G. Batchelder

WILKES-BARRE, PA., May 31—"Giant's Despair" is the rugged name given to Wilkes-Barre Mountain. It's a real climb, a mile and an eighth long, contains a sharp turn designated as the "Devil's Elbow," and, of course, has an "S" turn. The rise is some 700 feet, with grades that vary from 10 to 22 degrees, and the surface is uniformly good, more than average.

Once upon a time, in the early days of automobiles, more than one motor-driven vehicle discovered that the task was too great and therefore found it necessary to take another route. 'Twas in the year 1906 that the mountain lost its terrors to automobilists, and few cars there were in that climb which failed to make the ascent. First of all was an English Daimler, driven by Harding; since then its figures of 2:16 1-5 being reduced each year by substantial cuts. Power and reliability are now synonomous.

In 1907 Walter White's White Steamer appropriated the honors in 1:49 4-5, and in 1908 the Chadwick Six, with Willie Haupt at the wheel, accomplished the upward journey in 1:38 2-5.

To-day the big Benz from Germany, with its 120-horsepower,

Cars Were Given a Rolling Start and Were in Good Action When They Struck the Electric Tape

plunged up the incline in 1:31 3-5, Brown, the amateur enthusiast, being at the helm and apparently enjoying the reckless pursuit of the phantom goddess, fame.

Less than five seconds slower was the Chadwick Six, of half the horsepower of the foreigner and adroitly handled by Larzelere. DePalma made a notable climb with his Fiat skeleton flyer, and fourth best was the sturdy Knox piloted by Dennison and endowed with only 50-horsepower.

But the real honors of the climb belong to the stock car participants, it now being possible for anyone—and such is the case in most instances—to buy for his own use cars similar in construction and ability. If one wants a powerful road traveler. he can be sure of getting it in the purchase of a duplicate of the six-cylinder National which climbed skyward in 1:45; or in "fours" he might pick a 60-horsepower Stoddard-Dayton, which made the trip in 1:46 2-5. Still continuing in the "Big Fellow" bunch, one could select a Simplex with an ascent of 1:47 2-5, or a 40-horsepower Knox, the figures for which were 1:57 3-5.

Close up in to-day's list are Mathesons and American Roadsters, not forgetting that the smaller-powered cars consistently climbed at better than 30 miles an hour without distress or hesitation. Even a Babcock Electric only required 3 seconds more than 3 minutes to reach the mountain's top.

The fourth climb of Wilkes-Barre's club figured as a "National" event and the preparations for it were conscientious and almost complete. The contest committee, of which George F. Lee was chairman, with Wright, Steelman, Moore, Meixell, Wagner, and Lewis as his co-workers, struggled indefatigably, and only went astray in one real particular. That was in the guarding of the course. Thousands swarmed from the base to the top of the mountain, swarmed over the road, and seemed to be utterly oblivious or unconscious of the danger from the juggernauts that flew by in dangerous proximity. The next time, says Chairman Lee, there will be men and muskets in plenty, and there will be ropes alongside the tortuous climb its whole length. Then the fools will be kept out of harm's way. That a score or more were not killed was miraculous. It will be remembered that these same fools flocked all over the road at the Vanderbilt race. Here is what a local paper said about it:

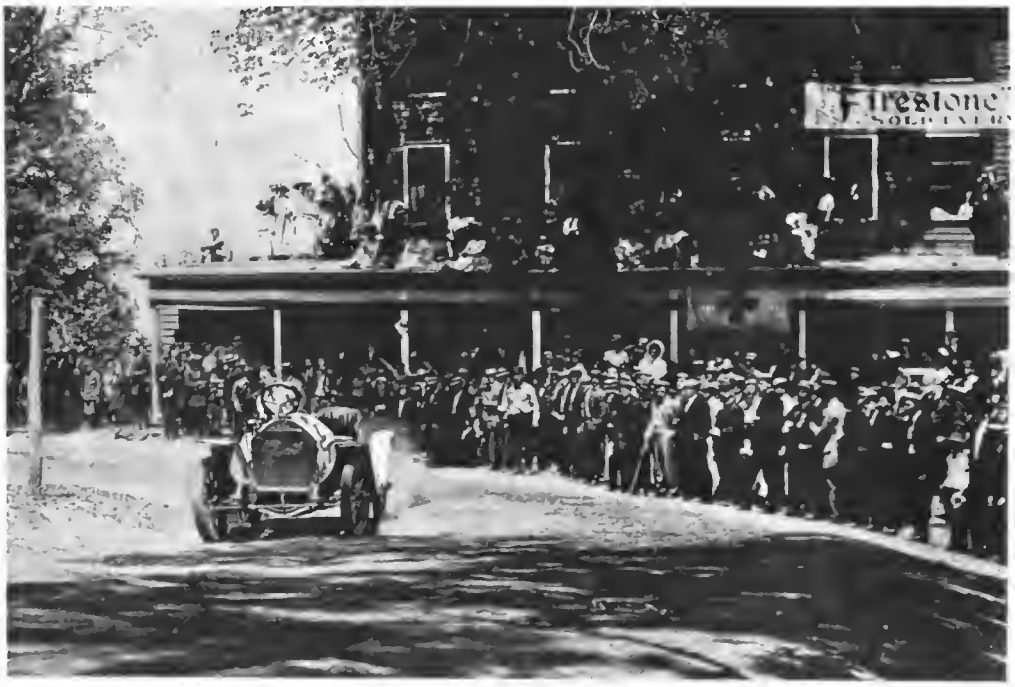
Knox Driven by Dennison, Which Was the Winner of Two Events

"Fully sixty thousand witnessed the exciting contests, and remained on the course from 7 o'clock this morning until the last car had gone down the hill. The crowd began to

arrive early, some of the most anxious ones remaining out all night so that they could get a vantage point—that is, a place where a machine might be wrecked or a driver killed.

"The race was a second Vanderbilt in point of crowd and excitement. The visitors arrived yesterday and flocked to the local hotels and garages. The Sterling last evening was like the Garden City Hotel on the night before the much larger Long Island event.

"This morning everyone was out bright and early, and until 9 o'clock the cars kept going up the hill. It is estimated that there were fully two thousand cars parked along the course and neighboring fields. The crowd surpassed that of all previous years."



Stoddard-Dayton, a Two-Time Winner, Rounding Mountain House Curve

Yes, certainly it was not unlike a Vanderbilt race in the manner in which the crowd declined to give up the road to the contestants. Starter "Wag" expostulated and cussed and even fought in trying to keep the course clear near the start. Farther up it was even worse. But Providence must have been interested, for most fortunately no one was harmed and the catastrophes were minor in character.

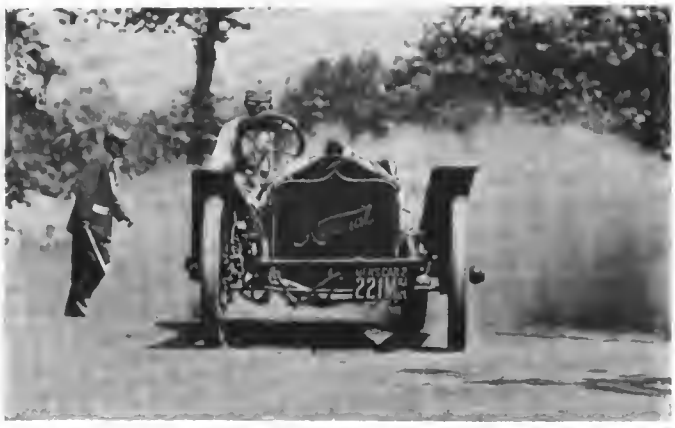
Chevrolet, who is not noted for his caution, had a spill while taking a curve pretty fast, and DePalma went into the ditch, but neither suffered any damage, and the only man hurt was a spectator who fell off a wall and sprained his ankle.

Chairman F. B. Hower, of the A. A. A. contest board, lent his official presence to the occasion, the referee of which was Samuel B. Stevens, well known as an owner and driver of fast racing cars. These two had some embarrassment in disposing of the importunities of Mrs. Joan Cuneo, who had an awful time because she was unable to obtain permission to participate in the speedfest. But there was "nothing doing" in her case, and so she had to be content with a ride down the hill seated alongside a mere man.

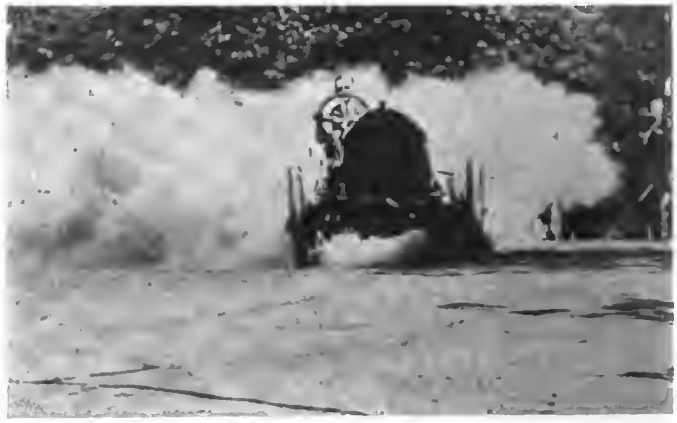
For three days before the climb, the contestants had the opportunity of practicing on the course, the result being that while some obtained experience without damage to themselves, several were put out of the running through accidents which luckily involved only the cars themselves.

From a spectacular point of view the free-for-all held the public interest. The thousands wanted to see the cars extended to the danger limit and beyond. Amateur Brown is a pretty good pilot for the big Benz and there were gasps in plenty as he rushed upward through the lanes of people and around

Charles Basle, Driving Matheson, Finishing at the Official Stand on the Top of Giant's Despair



"National" Winner of the Six-Cylinder Event



Pilot Larzelere Driving the Big Chadwick

the hazardous curves. Larzelere made almost as thrilling a climb with the Chadwick, which he subsequently repeated in the invitation event with time that was one-fifth of a second better. DePalma had an innings of ill luck. On his first attempt the electric timer failed to work; the second time he suffered a puncture, and on his third opportunity his lightweight racer nearly left the road.

The motorcyclists had a look-in and both events were captured by Wray with an Indian, his best in 1:41 2-5. The summary:

FOUR-CYLINDER GASOLINE STOCK, $4,000 OR OVER

Poe.	Car.	H.P.	Name of Entrant.	Driver.	Time.
1.	Simplex	90	Simplex Auto Co.	Wateon	1:48 3-5

S. F. EDGE COMES TO AMERICA

S. F. Edge, the well-known British autoist, is taking a look at things American, having arrived Friday last on the *Celtic*. Mr. Edge will be on this side possibly for a fortnight, and during that period he intends to make the most of his time. His American impressions will be well worth the reading, and it is a certainty that such a good publicity expositor as he is will not neglect the opportunity to supply interesting "copy."

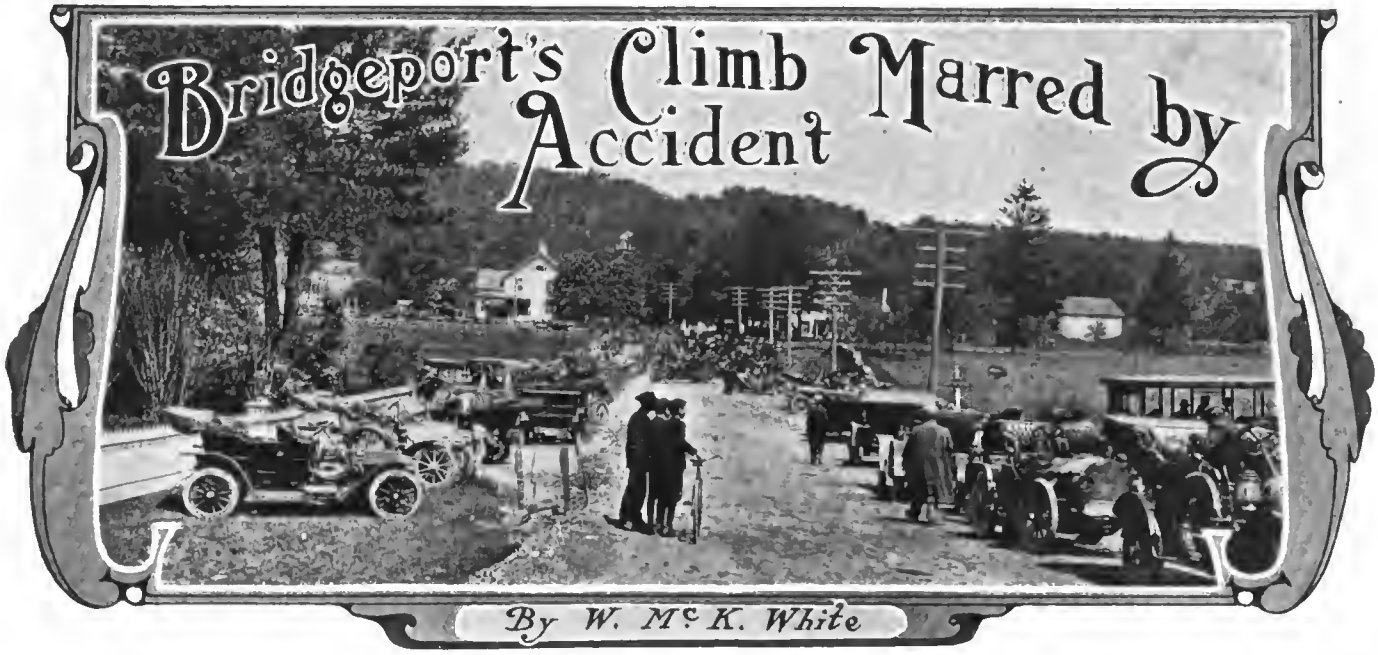
Chairman Hower and President Lee Talking It Over

Bridgeport's Climb Marred by Accident



By W. McK. White

Scene at the Bottom of Sport Hill, Typically New England, with Stone Fences and White Painted Houses

BRIDGEPORT, CONN., May 31.—Sport Hill, the steepest within many miles of this city, was to-day the scene of the third annual climb of the Automobile Club of Bridgeport, and up its perfectly groomed slopes records made in previous events were completely shattered. Seven times did the performance which was considered phenomenal and best last year fall before the swifter cars this morning, and had not the free-for-all been most unfortunately interrupted it is probable that the former record would have been still further relegated to history. Tried racing cars and well prepared stock touring cars, roadsters or stripped chassis, competed with success, many driven by amateurs, until the best previous time of 1:17 was lowered to 1:09 3-5, with six intermediate marks, and two others which equalled the 1908 best.

Joe Tracy in 1907 set up a standard of 1:24 2-5 in a Locomobile Vanderbilt racer; and in the Isotta, which captured many laurels in 1908, Al Poole cut many seconds from that, placing the record at 1:17. To beat this trip of Poole's was the problem before those who rode to-day over a road perhaps slightly better than previously, and with weather conditions ideal. To H. W. Webb in a Panhard of 120-horsepower went the premier honors, his time of 1:09 3-5 setting the new record.

A most unfortunate accident marred the affair just at its conclusion. In the free-for-all, with just two more cars to make the ascent, Glenn Ethridge started up in John H. Tyson's victorious Isotta, and at the worst turn of the course was going very fast. A combination of circumstances—high speed, sharp curve and skidding over the crown of the road—slewed the big car into the ditch and before Ethridge could get it completely under control it had started for the crowd at the roadside. Six men fell before or around it, all seriously injured, one of them possibly fatally, with broken legs and internal concussions. Bicycles were demolished, a tree cut off and a stone wall struck. William Walker, the mechanic, rolled off the car, but Ethridge kept his seat until the machine stopped and the engine was shut down. The militia cleared the course and doctors were soon at hand to minister to the wounded. Surgeons had been stationed at the curve, and fortunately there were others on the course. Touring cars were used to carry the men to the city hospitals after they had received temporary treatment at the roadside. The contest was declared finished. It was the opinion that the Isotta had done most of the damage by side-swiping, rather than by actually running over any one, and no blame was attached to Ethridge. It had been difficult at all times to police the course, for there were at least 10,000 persons massed along a mile of roadway, and the company of the Coast Artillery, 14th Connecticut, under Captain Hawes, did its best to keep the spectators back.

Bourque (Knox) Rounding a Turn

Sport Hill, an even mile in length, has a location permitting of a rolling start, then a comparatively easy grade on a straightaway of about 150 yards, a slight curve to the left and a steeper ascent for 100 yards. The real test is just above this point, where an "S" curve occurs upon a grade of about 12 per cent. All of the faster cars swayed terribly in getting around the lower half and more than once the crowds thought that the machines would turn over. It was just such an occurrence that happened to the big Isotta. From the upper part of this difficult section there was a nearly straight run to

Chalmers-Detroit, Winner of the $3,000 Runabout Class, Crossing the Bridge Near the Starting Point

the finish at the top on a practically level stretch. All along the way there were automobiles parked, perhaps 250 lining the upper reaches, and at vantage points the crowd was thickest.

Shortly after 8 o'clock the first car was sent away. It was a little Maxwell Junior in a class for gasoline cars costing under $850, and it was followed by one of the new four-cylinder Maxwells, driven respectively by Barnes and Goldthwaite. The latter won in the good time of 2:19 4-5.

The record for the course had its first attack in the fifth event, a class for runabouts of the same price division as the touring cars in the fourth, and Lorimer piloted a Chalmers-Detroit roadster up the hill in 1:16 2-5, 3-5 of a second better than ever before done officially. Harry Tuttle, in a 45-horsepower Stoddard-Dayton roadster, was second in 1:23, and C. B. Tiley, in a "Tiley," a newcomer and the latest production of Bridgeport, was third in 1:27 2-5. The Tiley car has a "short" four-cylinder motor of 5-inch bore and 4 3-4-inch stroke and full floating rear axles with shaft drive.

The first large field of the day was brought out in the eighth event, one for amateur drivers of gasoline cars, and it had seven starters and six finishers. It was in this class that the big Panhard had its inning and made the record. The car went up very easily, and in comparison with others which traveled at high speed it had less trouble on the curves, hardly skidding at the "S" turn, although it went by like a flash of blue. Broesel in the Simplex was second, his time being 1:16, slightly better than when he won the class just ahead. Alden in a Chalmers-Detroit was third in 1:17 1-5, and Doig in a Stearns fourth in 1:21 2-5. Another Stearns, driven by McNiel, was but 2-5 of a second slower than Doig. The Tiley car showed consistency by ascending in exactly the same time as before, 1:27 2-5.

That the free-for-all was going to furnish excitement was evident as soon as it started, because of the remarkable manner in which previous records became back numbers. Bourque flew up in 1:10 1-5 in the Vanderbilt Knox car of 38-horsepower, closely followed by Coffey in the stripped Columbia racer in 1:11 1-5, and then by Lorimer in a Chalmers-Detroit in 1:17. Harry Cobe had a six-cylinder Lozier in action, and its time was 1:22 1-5. Alden had a fast Chalmers-Detroit next, and it gained the under-the-record class by covering the course in 1:15 3-5. The Renault racer had difficulty in making speed because of its lack of a differential, and it skidded badly on the curves, thereby losing traction and time. Near the finish a tire blew out and that further retarded it, so that its time was snapped at 1:22 3-5. Following the Renault was the Isotta driven by Ethridge, and after it would have been the Panhard and another Isotta.

A. L. Riker acted as referee. The contest committee of the club is composed of: Chairman, Ralph M. Sperry, G. S. Bryan, F. W. Bolande, J. B. Lyford, F. A. Rantz, A. K. L. Watson, A. H. Canfield, W. W. Nichols, H. M. Lyon, H. B. Stoddard, F. T.. Staples, B. H. Edwards, H. D. Gates, A. McNeil, Jr.; R. C. Sherwood, F. L. Mills, F. A. Strong, E. W. Hanke, E. W. Fairchild, H. D. Miller.

QUINTETTE OF CARS LEAVE NEW YORK FOR SEATTLE

TWO Fords, a Shawmut and an Acme, of America, and an Itala of Italy are en route from New York City to Seattle as the contestants in the ocean-to-ocean endurance contest for the M. Robert Guggenheim transcontinental trophy. At 3 o'clock Tuesday afternoon, June 1, when it was just noon in Seattle, President Taft pressed a button in the White House which gave signals in the metropolis and in the city on the Pacific coast, starting the contest in the East and the Alaska-Yukon-Pacific exposition in the West. When the telegraph instruments showed to the group on the City Hall steps that the President had pressed the golden key, Mayor George B. McClellan fired a shot from a golden revolver, starting the five cars on their long journey from the Atlantic Ocean to the city on Puget Sound. The contestants had been parked in front of the public building some time earlier, fully equipped for a long distance journey, but the enormous crowd which gathered was kept at a distance by a cordon of mounted and foot police. At the shot the machines pulled into line, and, following a police officer in a conspicuous yellow taxicab, proceeded up Broadway, through "Automobile Row" and on toward Poughkeepsie, the first stop for a night, whither they were preceded by a pacemaker.

The Fords attracted a great deal of attention, not only because of their size but also because of their general get-up. The motors had no mufflers, exhausting through an opening in the side of the hood into the air. The body consisted of two seats for the drivers, with a platform at the rear for carrying baggage and supplies, covered with a brown canvas. The chassis was stripped of everything not absolutely necessary, such as fenders and the running gear was painted a dull gray. Natural colors remained in all other parts, such as aluminum unfinished for the bodies, sheet iron unpainted hoods, and unpainted gas and oil lamps. Henry Ford was on hand to see that the little machines were started safely, assisted by his New York and Philadelphia branch managers, Gaston Plaintiff and Louis C. Block.

The big six-cylinder yellow Acme was the only representative of the six in the contest, all of the others being fours. This car is fitted with bucket seats for four people, and the big gasoline tank is between them. Tires are carried at the rear and supplies in large boxes on the running boards. The Acme was the largest of the quintette, and carried a full load of passengers.

Shawmut was the fourth to leave the plaza in the line, and it was particularly noticeable because of its extra large wheels, using 40-inch wheels and tires, with a body for four men, tires and suppplies being carried between the two seats. These are extra high at the back and have small side strips carefully upholstered to act as head-rests when one set of drivers takes a sleep. The car is painted white.

The only foreign representative is the Itala, which was entered at a late moment, but it was fully prepared, with a special demi-tonneau body for four passengers and with the supplies carried in the tonneau and the tires at the rear. It is painted a lead color and stripped down as much as possible. The Shawmut and Acme are the only ones carrying running boards and mud-guards. All of the tourists started in conventional khaki uniforms.

A six-cylinder Ford roadster is being used as a pacemaker and carries the Automobile Club of America representative, and will go ahead of the cars as far as St. Louis. The competitors will not be allowed to pass it. The rules provide that the cars must stop each night at certain places which have been selected. The run on Tuesday was to Poughkeepsie, 73 miles; that on Wednesday to Syracuse, 207 miles; to-day, Thursday, to Buffalo, 150 miles; Friday to Toledo, 296 miles; Saturday to Chicago, 244 miles, and Sunday to St. Louis, 283 miles. From St. Louis the contest is a free-for-all one, the only requirement being that the cars must check at certain points en route to show that they have not cut the course. The engine base, cylinders, transmission case, steering gear, frame, front and rear axle of each contestant were stamped by the A. C. A. The following are the names of the cars with their horsepower, crews and tires:

No. 1—Ford, 20 horsepower, Frank Kulick, H. B. Harper. Firestone tires.

No. 2—Ford, 20 horsepower, B. W. Scott, C. J. Smith. Firestone tires.

No. 4—Acme, 45-50 horsepower, George Salzman, F. R. Sheets, Jerry Price, J. A. Hemstreet. Firestone tires.

No. 5—Shawmut, 40 horsepower, T. A. Pettingill, Earl Chapin, Robert Messer. Diamond Tires.

No. 6—Itala, 45 horsepower, Gus Lechleitner, F. B. Whittemore, Elbert Bellows. Continental tires.

Pacemaker—Ford, 40 horsepower, F. W. Teves, John H. Gerrie.

Ethridge Driving the Isotta at Bridgeport Climb, Just as It Began Its Fatal Dash Into the Ditch and the Spectators

FINAL ARGUMENT IN PROGRESS IN SELDEN SUIT

BEFORE Judge Hough in the United States Circuit Court, Southern District, there is being heard the final argument in the so-called Selden patent suit. One whole week was allotted for the concluding argument, it having begun on Friday last, and will end Friday of this week. From 10.30 A.M. to 5 P.M. daily, with an hour's intermission for lunch, the courtroom in the New York Post Office building has been thronged with the most notable array of attorneys, possibly, ever engaged in patent litigation at one time.

While it is true that any decision by Judge Hough may be carried to the Court of Appeals, the impression prevails that the effect of his decision will be substantial and satisfying to most of those concerned in the long-drawn-out story which began in the early days of automobiling in this country, due, to a great extent, to the organizing genius of the late George H. Day. Even opponents recognized the ability of this man.

The legal battle is in the form of suits brought by the Electric Vehicle Company and George B. Selden against the Ford Motor Company as manufacturer, John Wanamaker as dealer and agent, C. A. Duerr & Co. as dealer and agent, and the O. J. Gude Company as user of a so-called unlicensed car. Additional suits are against the American branch of Panhard & Levassor, of Paris, and Henry Neubauer, importer of foreign cars. Of course, the A. L. A. M. is the power behind the suits.

These various suits involving manufacturer and dealer and user and foreign maker and importer cover the entire situation. The legal talent is more than notable. The "licensed" list includes William Redding, well known for many years in patent matters; Betz, Sheffield, Bentley & Betz; Greeley & Austin, and Frederick P. Fish, of Washington, D. C., who will probably make the final presentation on Friday.

R. A. Parker and W. Benton Crisp represent the Ford Motor Company and also look after the interests of John Wanamaker, C. A. Duerr & Co., and the O. J. Gude Company. Cordoza & Nathan are also general attorneys for the Ford Company, while Coudert Brothers represent Panhard & Levassor and Henry Neubauer.

It is expected that the summing up Friday will attract many prominent men of the automobile industry, for brilliant arguments are assured. While it is considered probable that an appeal will go to the Court of Appeals, it is believed that nothing will ever reach the Supreme Court, which of its own volition only would interest itself in considering the evidence transmitted from the Circuit Court to the Court of Appeals.

A prodigious amount of testimony has been adduced from both sides, but it would appear from his occasional comments and rulings that Judge Hough has a fairly comprehensive idea of the importance of the suit being tried.

WILLYS ANNOUNCES TOLEDO PLANT PLANS

TOLEDO, O., June 2—The Overland Automobile Company has finally arranged all details for the purchase of the plant of the Pope Motor Car Company in this city, and prior to leaving for a seven weeks' trip to Europe, J. N. Willys, president of the Overland company, announced the policy of the company to be as follows:

"Within a few days contracts will be let for erecting a three-story addition to the Toledo plant, 80 x 35 feet. This new part is to be occupied by the Kinsey Manufacturing Company, of Dayton, O., whose plant is to be brought to this city. Almost the entire output of this concern, which consists of automobile parts, will be used by our company, and the working force of this department is to be increased to 500 men.

"The purchasing, engineering, and sales departments of the Overland company are to be brought to Toledo immediately, and within four months between 1,500 and 2,000 men are to be employed in the local factory.

"Orders have already been placed with us for 5,000 cars for next season, and the output will probably not be less than 10,000, and more likely 15,000. Of this number one-half are to be manufactured in Indianapolis.

"Contracts have already been let for over $50,000 worth of new machinery, which is to be placed in the new department, and also to replace certain present machines which are somewhat antiquated, or at least can be replaced by much later ones. The present plan is to manufacture two grades of machines, selling for $1,250 and $1,500 respectively."

METZGER BECOMES INTERESTED IN WHEEL

CLEVELAND, May 31—William Metzger, who recently sold his interest in the E-M-F Company, has become identified with the Seaton spring wheel. As to the extent of his connection with the company nothing has yet been definitely announced, but it is understood that he will give considerable of his time to what will be known as the American Spring Wheel Company, the foreign patents of which will be handled by the International Spring Wheel Company. H. L. Olmstead has accepted the position of engineer for the American company.

AUTOMOBILES MET THE EMERGENCY

ATLANTA, GA., May 31—When the firemen of the Georgia Railway went on a strike and sewed up the entire line—some 307 miles long—so tight that never a wheel turned from May 23 to the night of May 29, they gave automobiles a wonderful opportunity to dash into the limelight.

The newspapers were the first ones to face the problem of getting into this territory. The night the strike became effective, the Atlanta *Constitution*, a morning paper, started a car down the Georgia road. The next afternoon the afternoon papers raced cars along the Georgia road, delivering seventy-eight miles down the line, despite roads softened by a two weeks' rain.

After various cars had tried their luck at fast running through the mud, the Southern Branch of the White Company cornered the paper transporting market, and five or six steamers were in service every day, carrying tons and tons of papers as long as the tie-up lasted. These newspaper cars carried mail as well as papers, and picked up an occasional passenger.

But the taxicabs and other motor cars did the main passenger business, traveling hundreds of miles up and down, parallel to the trainless Georgia Railway, and conveying to and fro such passengers as had urgent business and the wherewithal to pay.

NEW YORK WILL TREAT ORPHANS RIGHT

NEW YORK CITY, May 31—As the Annual Automobile Day approaches the interest increases and the prospects for the largest event in the past five years also improves. The committee is hard at work raising cash and securing the use of cars for the day. Up to date over 75 cars have been secured and more are in sight, of which 12 are taxicabs, 6 of the W. C. P. Yellow Cab line, and 6 red taxicabs.

Arrangements have been made with the management of Dreamland to throw the whole show wide open on that day, and there it is that luncheon will be served, although the problem of paying for it has not been solved.

A new plan of forming the parade and laying out the route will be adopted this year on account of the opening of the new Queensboro Bridge. The parade will form in the streets of Automobile Row, north of Columbus Circle.

Automobile Gasoline and Other Available Fuel

Part VIII

By Thos. J. Fay

TIMING the spark is not all that has to be done in order that the mixture will afford the maximum result. If valves are used, as they are in 4-cycle motors, they have to be timed in such a way as to admit the charge to the fullest possible extent, and to allow the spent products of combustion to escape. In 2-cycle motors valves are not used, and in them it becomes a matter of perfection of design in order to afford the desired results. The relative advantages will be discussed at the proper time, and for the present it will be the aim to point out a certain similarity in them, in so far as the fuel problem is concerned.

In general, no matter what may be the way of admitting the mixture and scavenging, the results will only be the same if the mixture is admitted at the same time and if the exhaust is allowed to escape under similar conditions. If a motor, because of defects in the methods of design, will not afford the requisite time for the mixture to enter the cylinders or the exhaust to escape, the power stroke will not be so effective and the power of the motor will be reduced.

In such a motor, if the exhaust is imperfect, the speed will be reduced, and in consequence the power of the motor will be reduced, because the number of power strokes will be less. In the same motor, if the intake is restricted, the torque will be diminished and the power will be reduced more rapidly as the speed increases, because the torque will reduce more rapidly than the speed increases. If it takes a given period of time for the mixture to enter a cylinder this fact will not be altered because the design of the motor is changed. An abstract fact is not changed merely because the design thwarts the plan, and the lesson to be drawn is obvious.

These are matters of more than a little importance when designs are being considered, and any design that prevents complete scavenging must offer other advantages to offset the disadvantages, or the results will be below a fitting standard. Torque is equal to the sum of the power strokes, minus the sum of the power-consuming increments. This same torque, which is but another name for torsional moments (torque, to twist), may be due to the power stroke in one or two more cylinders, and it may be due to:

(A) One power stroke for every four revolutions, as in 4-cycle motors.

(B) One power stroke for every two revolutions, as in 2-cycle motors.

(C) One power stroke per cylinder, per complete cycle, in any motor.

The sum of the torque increments might be the same, irrespective of the number of cylinders, and independent of the cyclic relation, for the reason that the torque is proportional to the weight of fuel burned to complete combustion, and it would seem as if practical limitations are such as to thwart all the designs beyond a certain point. Of course, there is a certain advantage to be expected from a large number of light torque impulses, in comparison with a few of such impulses, in a given time. On the other hand, it is the general impression, gained in practice, that one good power stroke is of far more advantage than two "soft" power strokes. There is some truth in the idea.

The probabilities are that the practical way of putting it falls short of a true explanation, due to the complicated nature of the problem and the lack of understanding of both sides of the subject by any one of the practitioners. It cannot be claimed that the results will be different if the sum of torque increments of the power strokes are the same, considering two types of motors, but it may be true that one of the motors will deliver its impulses with greater regularity, due to better conditions of scavenging, from the point of view of regularity. That regularity is one of the grave necessities is true, and this phase of the problem is sometimes overlooked, nor can this much desired property be depended upon in a motor that does not enable the spent products of combustion to escape quite completely.

Valve-Timing Classes in the Fuel Problem—Independently of the mechanical means of accomplishing the desired results, the time allowed for the gases to enter and leave the cylinders should be the same in any given sized motor, considering a given result per power stroke and a conventional design of motor. The following general considerations will be in order:

(A) The inlet should be opened at the earliest possible instant, even before the exhaust is closed, in types of motors that will allow of the practice; which is true in 2-cycle work, as a rule, and in some 4-cycle motors, especially when the crankshaft speed is high, as it is when the stroke is short.

(B) The inlet should not, of necessity, close at the end of the suction stroke, nor is it good practice to set the closing of the inlet the same in all designs of motors.

(C) The exhaust should open before the end of the power stroke, as it does in 2-cycle motors, and in nearly all 4-cycle motors as well. Just when to open the exhaust is a matter that is not easy to settle upon, and that it will not be the same in all designs of motors is a matter to be taken for granted. In a long-stroke motor, for illustration, while it would do no harm to open the exhaust early, very early indeed, the advantage in doing so would be but slight. In short-stroke motors the advantages of an early opening are assured, and disadvantages are also present.

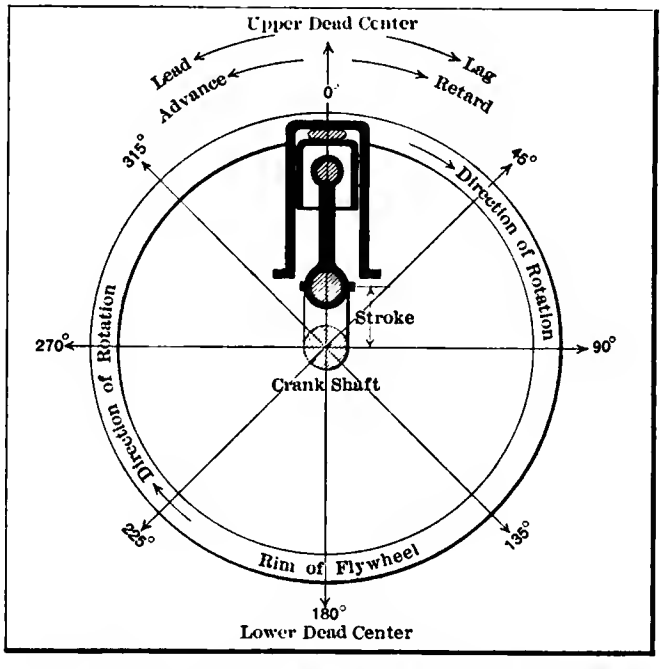

Fig. 40—Diagram depicting relations of advance, retard, lead and lag in the process of timing valves and the ignition.

(D) The closing of the exhaust is of equal importance, and if the motor is of the high-speed variety it is probable that the valve can remain open until after the inlet is opened.

(E) Valve-timing, from what has been said, is a matter that must take into account the speed of the crankshaft and the stroke of the piston. It is a case of balancing the gains against losses.

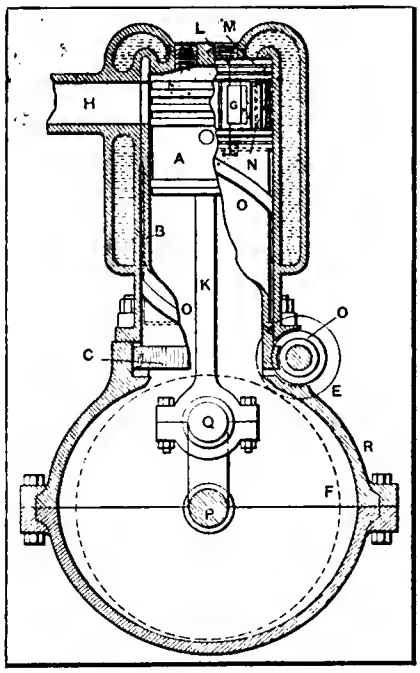

Fig. 41—Cross-section of a Ledru two-cycle motor, showing a rotary valve system.

Fig. 40 will render clear the terms advance, retard, lag and lead. As the figure shows, when the spark, for illustration, is advanced, it is caused to propagate earlier in the revolution of the crank, so that to advance the spark it is necessary to cause the same earlier, and the word "advance" really means that the spark is advanced against the revolution of the crankshaft. Likewise, a retarded spark is one that is propagated late in the revolution of the crankshaft. A fully retarded spark is one that is produced under ordinary conditions (on the power stroke) at about 5 degrees. A fully advanced spark is one that is produced (on the compression stroke) at about 315 degrees, which angle represents 45 degrees, before upper dead center, and $360-45=315$ degrees. This angle is more than is customary in motors in general, yet even so it is not more than the mechanism should afford, in view of the conditions that are possible in modern high-speed work.

The upper dead center is marked as 0 degrees, so that all angles are computed from this point. In dealing with the early and late opening and closing of the valves (on the bottom dead center), all valves that close before 180 degrees close early, and all valves that close after 180 degrees close late. If the admission valve remains open for 15 degrees beyond the bottom dead center, for illustration, it will close late, and the angle of closing will be 195 degrees on the inspirating stroke. On the other hand, if the exhaust valve opens 45 degrees before the bottom dead center it is said to open early, and the angle of opening will be 135 degrees on the power stroke.

Example of Angles in an Average Valve Timing—Considering a motor at a speed of 1,400 revolutions per minute of the crankshaft as representing an average case, the valves would do satisfactory work were they timed in the manner as follows:

Lead given in opening the exhaust valve....	45	deg.
Lag in closing inlet valve.....	15	deg.
Lag in closing exhaust valve.....	7½	deg.
Lag in opening inlet valve.....	15	deg.
Exhaust valve opens on the power stroke.. ..	135	deg.
Inlet valve closes on the compression stroke.	195	deg.
Exhaust valve closes on the suction stroke...	7½	deg.
Inlet valve opens on the suction stroke.....	15	deg.

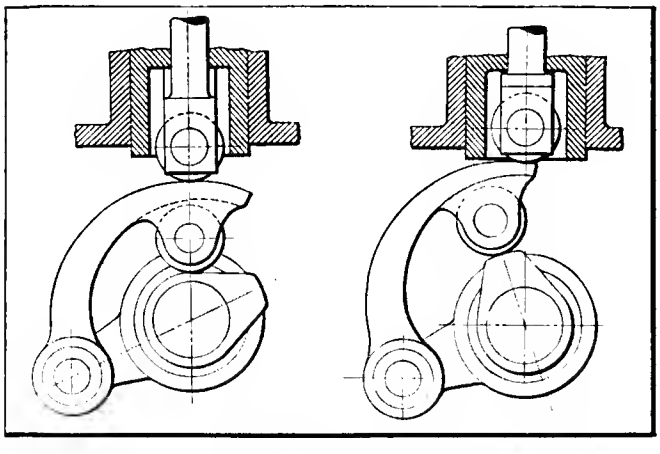

Fig. 42—Scheme for accelerating the process of adjusting the timing of valves by means of a cam-follower.

Under certain conditions it would be possible to open the inlet valve early and close the exhaust valve late, but this is not a condition that is to be recommended as a general proposition, in the absence of definite information in relation to the motor and the service to be rendered by it.

In closing the inlet valve late on the bottom dead center it is the aim to take advantage of the inertia of the gas stream, and if the design is right there is no question as to the resulting gain. There is one other point to be considered—it is only possible to time the valves if the design is such that the inlet and exhaust valves are separated from each other, as they are in poppet-valve motors. Take the rotary valve, for illustration; it is not one that will lend facility to a plan of overlapping the opening of the inlet with the closing of the exhaust. Indeed, there must be a period of time when both valve ports will be closed, since there must be a separating wall between the inlet and the exhaust ports. Fig. 41 shows a motor in section, in which the timing of the valves is due to the rotation of a sleeve inside of the cylinder walls, within which sleeve the piston reciprocates. In this motor, which is of the "Ledru" type, the action is on a two-cycle basis, and while it is not of a design that will lend itself to timing variations, it is the aim to compensate for this by two-cycling, thus doubling the number of power strokes. Referring to the figure, it is to note that the piston A works inside of the sleeve B, which sleeve is rotated by the worm-gear C, actuated by the worm D, driven, in turn, by the gear E, taking its power from the crankshaft P through the large gear F. The rest of the performance is not of interest from the point of view of this discussion, hence this type of motor will be dropped for the present.

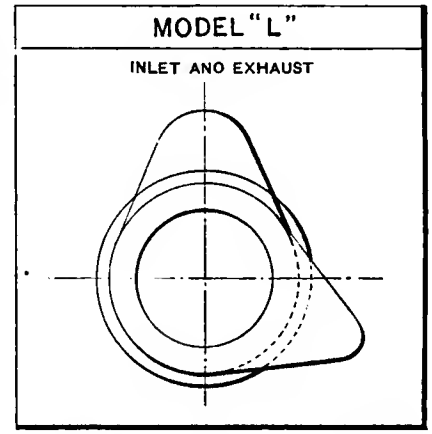

Fig. 43—Maxwell camshaft for inlet and exhaust valves combined, showing contour.

Means for Adjusting the Timing of Valves—Even when poppet valves are used it is not possible to alter the timing after the design is completed, excepting within narrow limits, unless some special device is introduced for the purpose, and even then it is a question if the added complication is not considerable of a load to carry, considering that the design might be made once and for all on a basis to exclude all such complications. Fig. 42 shows one way of affording a means of ready adjustment, a description of which was given as follows:

Variable Valve-Timing Mechanism—"It will be seen that the cam follower remains the same as in average practice, as does the cam also, but that the action between the cam and the so-called follower is not direct. Surrounding the camshaft, and using it as a fulcrum, is a lever. To the outer end of this lever is fulcrumed a second lever, which carries a roller for making contact with the cam directly and communicating the motion of the cam through itself to the reciprocating follower. In action it is possible with this device to vary the times of valve opening and closure through rotating the first of these levers about the camshaft in the desired direction."

Timing as It Is Practised in Maxwell Cars—What actually transpires in practice is of the greatest utility, particularly when the results are commendable. The table that follows shows the

practice in connection with Maxwell cars of the several types, and the cams are shown in Figs. 43, 44, 45, 46 and 47. The figures are given full size, so that it is possible to note the contour, and it is one of the points of merit in these cars that the action is noiseless and the cams are efficient and durable. The table is sufficiently clear to require no further explanation, and, while the angles of opening and closing of the valves may not fully accord with the practice in some other cases, it seems to be right for Maxwell motors at any rate.

In Further Relation to Opening Inlet Valves—It rarely ever happens that the inlet valves are opened early, nor can it be shown by any line of reasoning that an advantage will follow if inlet valves are opened early. A late opening assures that there will be a depression in the chamber when the inlet valve opens. That there should be a depression in the chamber at the time of opening of the inlet valve is one of the points that can be made, and it is also true that a considerable lag, in degrees, on the periphery of the flywheel means but a small depression in the chamber. It will come as no great surprise, then, to note that in some motors the inlet opens very late indeed. As an illustration of a case with a very late opening, attention is called to the Unic, 20 H.P., in which the inlet was found to be 34 degrees late. In the Maxwell cars, as the table shows, all the inlet valves open at 15 degrees late, which seems to be a good average figure in general practice, considering motors of the speed of the Maxwell.

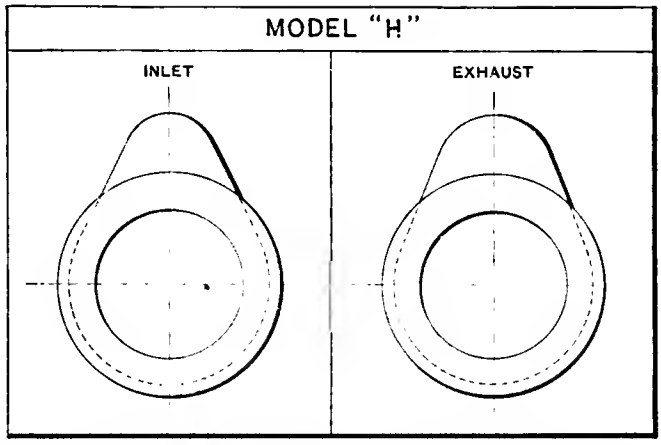

Fig. 44—Maxwell cams, showing a round-top contour in the inlet side, thus assuring an adequate opening.

while the valves may open on time and, in so far as they are concerned, do all that can be fairly expected; even so, if the exhaust is retarded (beyond the valves) the results will be inferior.

Fig. 48 depicts an effort on the part of the Pierce designers to afford an easy exhaust; indeed, they go so far as to attempt to generate a vacuum in the exhaust manifold, with the idea

TABLE SHOWING TIMING ANGLES FOR MAXWELL MOTORS AND OTHER DATA OF INTEREST

Timing of Valve in Degrees and Equivalents of Inches on Fly Wheel

K	15° late	2.487″	40° late	6.633″	40° early	6.633″	10° late	1.691″	19″	4¼″	4.25″	4 vert.	6.5	800	1200
M	15° late	2⅜″	40° late	7″	40° early	7″	10° late	1¾″	20″	5″	5″	4 vert.	10	800	1200

NOTE—In timing valves, piston should be on upper dead center.

In any event, there is one point that is assured on the face of it: there is nothing to be gained in opening the inlet valve sooner than gas will flow in, and that is when a depression is created. On the other hand, there is a decided advantage in keeping the exhaust valve open as long as possible, and this is only practicable when the inlet valve is opened late, unless it is desired to have both valves open at the same time. That they can be open at the same time is true in high-speed motors, but it is a question if flexibility will still be present. Certainly there is some chance of popping in the intake if the two valves are so open, provided the speed of the gas is slowed down sufficiently, which will be true when the motor speed is low enough. Flexibility, then, is probably sacrificed in the motors that are so timed that the inlet valve opens before the exhaust valve closes. In the Maxwell cars the exhaust valves close 5 degrees before the inlet valves open, and this is an ample margin for safety. It is even a question if the Maxwell has not erred on the safe side, which, by the way, is a good fault in cars to be placed in the hands of users.

Certainty of action is one of the great points in favor of a fine performance in automobile motors in particular, on account of the entire absence of mechanical skill on the part of many autoists, and this certainty is not to be regarded as present unless the motors will perform when they are heated up as well as when they start out for a day's run. On this account it is necessary to pay attention to the exhaust to a marked degree, for of pulling the exhaust gases away from the valves, and in this way an attempt is made to increase the power of the motor. The idea is very simple, consisting only of so shaping the exhaust manifold that a nozzle effect will be engendered, and the area of the manifold is so calculated that the resistance against the efflux of gas is but slight, and well regulated besides. Tests

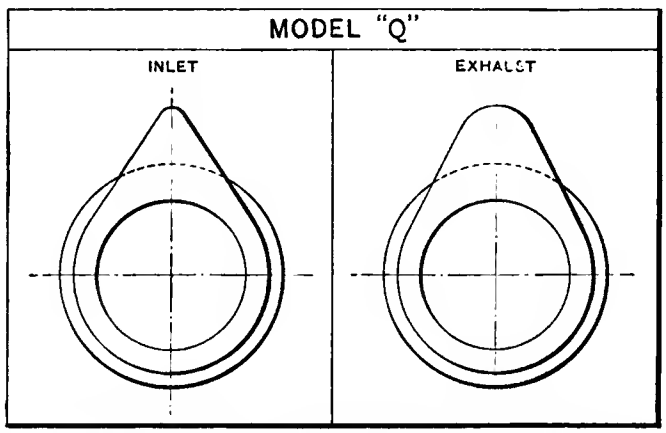

Fig. 45—Maxwell, with inlet cam, designed for the characteristics of Model Q motor

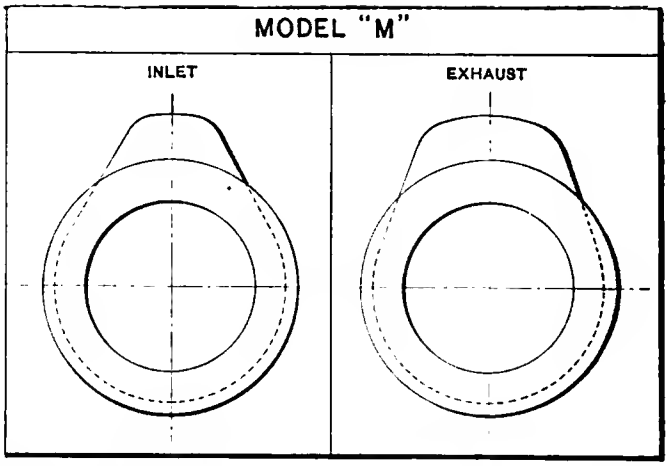

Fig. 47—Model M Maxwell showing cams that assure a long time opening and easy action.

of the Pierce exhaust manifold, as reported by the engineer in charge, were such as to encourage attempts of this character, and certainly it is at small cost, excepting as to skill, that matters of this nature can be incorporated into motors.

In some types of motors, notably in air-cooled work, the valves in the head are small, due to the manner in which they are placed, as depicted in Fig. 49, excepting that the illustration includes a way of keeping the valve springs cool, in that the springs are outside of the air jacket. That the valve springs have to be kept cool is a matter that proves out in the examples that do not include a means of cooling them. If the springs

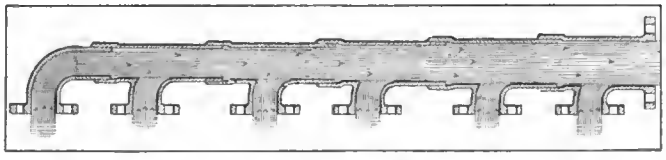

Fig. 48—Pierce exhaust manifold, designed to afford a vacuum, and an increase in power.

lay up against a heated wall, particularly if the wall is that which obtains in air-cooled work, it takes but a little while for the springs to become lazy. When the springs fail to work in a manner to assure quick closing, noise is made when the rollers fail to follow the contour of the cams, and what is more to the point, the timing is reduced to indifference. The design as depicted in Fig. 49 is defective, in that the valves are not in separate housings, although this is a matter that was mentioned earlier in this discussion.

As an example of very exact work, in which the question of the temperature of the springs is adequately cared for, Fig. 50 is offered, which represents a Pierce motor cross-section, and, among other details, a commodious roller hugs the cam, so that the life of the parts should be long, which is besides the point to be made here, *i.e.*, once the motor is timed, if the "tuning up" operation is properly done, it will stay so for a long time. This has not always been so in motors in general, and it is a matter of very serious purport, for when a car is handed to a motorist it frequently happens that it is to one that has never before "tried his luck."

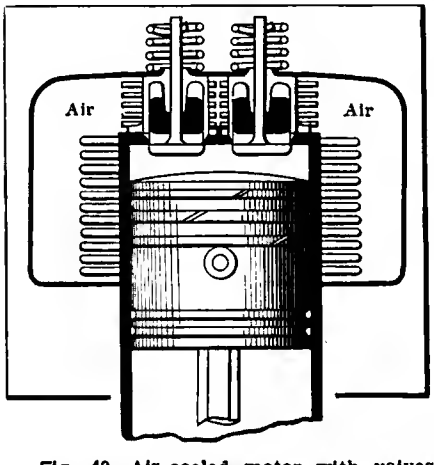

Fig. 49—Air-cooled motor with valves in the head and means for keeping the springs from over-heatng.

If the timing will not stay adjusted, and it will not unless the parts are properly made, the poor motorist will soon have to place himself and his car at the tender mercy of a garage keeper, who, in all truth, can do no more to remedy this defect than the owner of the car; the garage man can bill his time, nevertheless. Fig. 50 is also noteworthy in that it shows exact means for adjusting the valve-lift; moreover, the work can be done with ease by a man of no great skill, for the very simple reason that an adjustment is provided. In this case the adjustment consists of a special shaped cap-screw, threaded to screw into the lift, and a lock-nut is available to secure the cap-screw once the adjustment is properly made. In the head of the cap-screw, just where the stem of the valve contacts, a cushion is provided, the function of which is to prevent noise, which is so noticeable in the class of motors that make no provision to dampen the tapping sound. In this case the cushion is imbedded into the head in such a way that it cannot flatten, nor is the material prone to crumble. This is a point well worth taking into account.

The lift is of good proportions, with ample bearing surfaces, and the guide is of suitable bearing bronze, so that the life of the parts, which is really measured by the noise that will ultimately have to be taken into account, is nil, in this case, due to the manner of design, use of suitable materials and provision against eccentric pressures and harmonious relations of the parts.

(To be continued.)

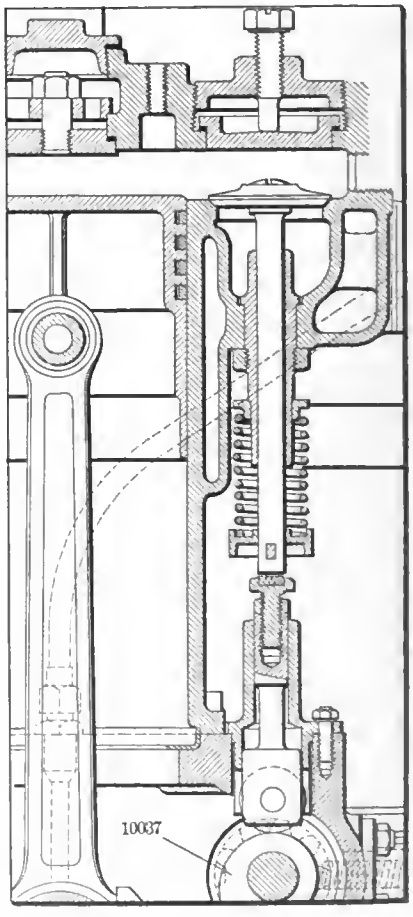

Fig. 50—Pierce valve-motion, showing manner of adjusting the timing and noise-preventing cushion.

ELECTRIC LIGHTING for AUTOMOBILES

By MORRIS A. HALL.

IT will be welcome news to many that much good work is being done along the line of substituting electricity for the present sources of light. This will be particularly attractive for use with headlights or searchlights where superior strength is more necessary, although it is possible that the present side and tail lamps may not undergo any alteration in this respect even with available electricity. This offers many advantages, such as cleanliness, convenience, superior light with its accompaniment, greater carrying capacity—that is, greater length of road illuminated. Providing that a proper source of current is provided there are no real disadvantages worthy of the name. The furnishing of this current up to date has been the insuperable obstacle to the use of this very desirable form of lighting and even now it is not an assured fact that the previously existing difficulties have been wholly overcome.

Typical Storage Lighting Battery

The Prime Sources of Current—The current supply is susceptible to treatment along two lines—that is, there are two possible sources of current supply. These are the dynamo and the storage battery. The former is a rotary current generator and actually produces current, while the latter gives this out only by chemical action, in the course of which material is altered in its form after the complete alteration of which a reverse or building-up action is necessary before more current is produced. That is, the storage cell for electric lighting purposes is only a different form of the storage battery used for ignition and is subject to the same failing, the necessity for recharging.

For car lighting a high discharge rate is a necessity, this being much higher than the ordinary discharge rate necessary for ignition. The question of ultimate use must be considered in the construction of the battery because the rate of current drain influences the internal construction. That is, if the cell was constructed for a low discharge rate and then is used for lighting or some other purpose requiring much current the greater rapidity of action is not only liable, but certain, to warp the grids or plates composing the battery. This results in both mechanical and electrical losses which can only be stopped by replacing the warped plate with a new one.

With a battery specially constructed for large flow the size, shape and arrangement is such that it does not effect any harm. This sums up in the statement that the battery if of the storage or accumulator type must be especially constructed for electric lighting purposes. Such batteries are now upon the market and may be had at any supply store. As the illustration shows, the external appearance is no different than any other storage battery, all of the changes being internal and hence not visible.

Dynamo Also Must Be Specially Built—Like the storage cell, the ordinary dynamo or magneto is not available without a number of internal changes, which amount to practically the rebuilding of the whole machine. First, the biggest problem in this connection is not the construction nor the winding of the machine, but the lack of a satisfactory governor to regulate the speed. To mention briefly the requirements is to outline the difficulty without further mention. These are: The speed of the engine or any other rotating shaft in the car is constantly varying; the dynamo must be driven from one of these changeable specd shafts and positively, yct its own speed must be very constant; in fact, in the best electric light work the maximum permissible variation is but 2 per cent.

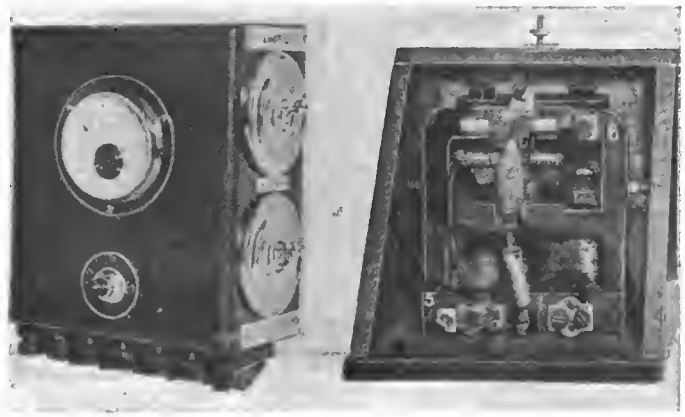
From this one may get an excellent idea of the difficulty, yet there have been many serious attempts at it and one of the latest looks very good. One way ordinarily used is the centrifugal governor, which at best is a rough means, while the problem would seem to demand a very delicate treatment. In an English machine, the Leitner, electrical methods have been substituted for mechanical means with this object in view, namely, the attainment of a continuous output at a constant pressure.

The dynamo shown in one of the small cuts is of the bi-polar shunt-wound enclosed type. The enclosing case shuts out the dust, keeps in the lubricating oil and is the acme of simplicity. The armature is mounted upon ball bearings to reduce the friction of rotation to as near zero as possible. In addition to the usual brushes another auxiliary pair are fitted which fulfill the function of regulating the pressure of the outgoing current regardless of the speed at which the generator is driven. They are set slightly in advance of the neutral axis and are connected in series between the ordinary shunt coils of the field magnets.

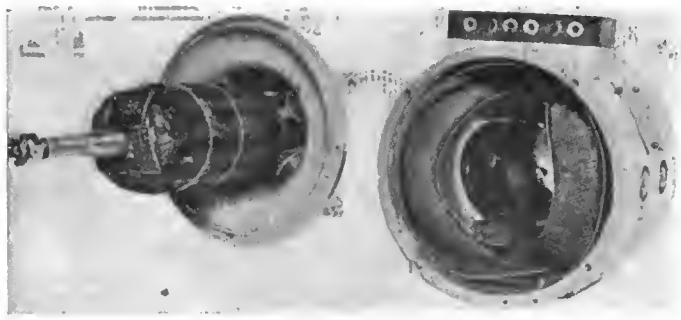
Auxiliary Brushes Add to the Current at Medium Speeds—At slow speeds and while the dynamo is being speeded up these brushes are picking up a small amount of current, which goes to assist the normal shunt current in the magnetization of the poles. As the speed continues to increase and approach a predetermined maximum, the magnetic field becomes more and more distorted until at the maximum point the original lead of auxiliary brushes is neutralized and the neutral zone has advanced and overtaken them. At this point the auxiliary brushes have no effect, and when the speed is further increased the distortion increases with it and current drawn from the armature by these brushes acts as a back EMF or in opposition to the normal shunt current. Throughout this whole range of change of speed only a change of potential takes place in the exciting current.

By so selecting the angle of advance of the auxiliary brushes any desired speed range may be obtained and the output of the machine controlled within these limits by the progressive assistance and neutralization of the excitation. So well have these angles been worked out that in actual tests it has been impossible to detect any variation in the main current using a voltmeter. Two pictures of the dynamo complete and of the rotating armature, with the field magnets in place just as the armature was withdrawn from them, are shown.

The action of the machine, which is the basis of a whole new lighting system, is to change the electrical conditions and thus,



Switchboard and Automatic Cut-Out in Two Views



Armature and Magnet Case of the Leitner Dynamo

rather than by varying the speed alone, govern the electrical output within well-defined limits.

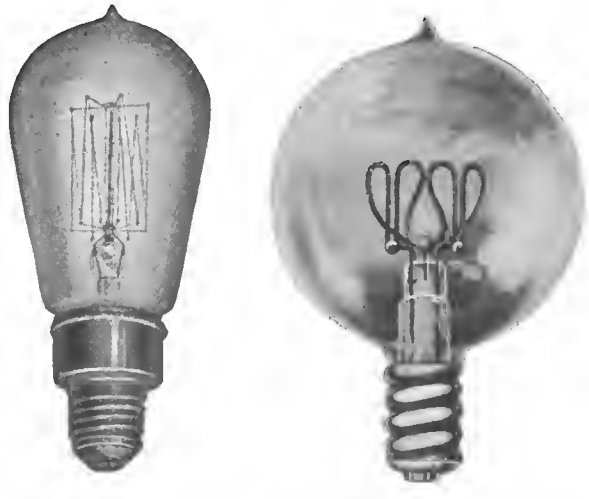
Automatic Switch Plays an Important Part—This newer system also includes an automatic cut-out switch, the function of which is to act as a non-return valve to the battery. The latter are fitted as an intermediary between the dynamo and the lights, the former being used to charge the battery, which in turn is used as the immediate source of current. When the generator is in use charging the cells the current flows through this switch in a normal manner, but as soon as there is a flow in the opposite direction—that is, from the battery to the generator, the switch is automatically pulled out owing to the reversal of the two poles of one of the magnets. Similarly the switch is automatically pulled in when the current from the generator becomes large enough to charge the battery.

In either case the action of the switch is electrically positive and it is magnetically held in the position into which the electric action forces it. This continues until the conditions again change and is not affected by vibrations, consequently its efficiency is not affected.

When the batteries are not furnishing current for lighting a two-way switch is made to insert a resistance in the field coils so that the output is reduced to a very small quantity.

Ignition Also Possible with This System—If desired, a coil may be fitted, and with the batteries as a source of current, the lighting system may easily be used for ignition of the engine. If this method of igniting the motor is adopted, it is advisable to fit another set of batteries for ignition purposes, and kept the set of lighting batteries intact for that purpose alone. This is advisable because of the different current drain on the batteries in the two cases necessitating a different form.

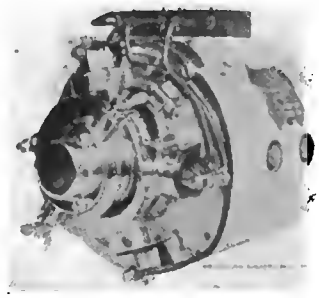
One of the most convincing proofs of a system like this, however well it may seem in theory, is an actual installation, and the subsequent results derived therefrom. As stated before, this is an English outfit, and the installations which are available are also English. The London General Omnibus Company has conducted a long series of experiments with it, and finding no faults as a result of these tests, has approved it for public use in passenger-carrying vehicles. Another London bus company has gone even farther than this in its appreciation of the real merit in the system. The Metropolitan Steam Omnibus Company tried it on a few cars and after these had traveled a distance in excess of half a million miles without untoward happenings and with no undesirable developments, all of the other cars belonging to this company were similarly equipped.



Two Ordinary Forms of Tungsten Light Bulbs

Considering the supply of current from a magneto on an automobile the point of difference between lighting and igniting conditions are three in number—variable speed, enormous voltage necessary to jump the air-gap and timing arrangements for producing the jump at the desired point in the engine cycle.

Granting the elimination of the first, the other two may readily be removed so that all that is necessary for the use of an ignition magneto for lighting purposes really is constant speed. In a motor boat, for instance, this condition obtains and frequently owners of motor boats cut in back of their coil (which produces the enormous voltage) and timer (which gives the spark at the right time) for current to operate a small lamp. Thus, the ordinary magneto might be depended upon to deliver 50 watts. Now small electric light bulbs of, say, 4 candlepower, would require about 4 1-2 watts per candlepower or 18 total. Then two of these could be used and still leave a large margin of current for ignition purposes. Thus if a system were used consisting of a storage battery and dynamo, with the latter furnishing the ignition current direct and charging the storage battery with the surplus, this system would readily adapt itself to lighting work in addition. Suppose the dynamo furnished 5 amperes and the ignition consumed but 2 amperes of this. The extra 3 amperes of current could be used to charge the storage cell, which in turn could be utilized for ignition. With the use of 6-volt 6-candlepower lamps, the current accumulated in ten hours would operate six lamps for five hours, or if more light is required, it would operate twelve lamps for two and a half hours.



Dynamo Shows Four Brushes

Economical Lamp Bulbs Are a Necessity—An inspection of the above shows that the current is very carefully distributed and conserved, so as to minimize the losses. With this in view it is apparent that any device that will economize on current still further is a desideratum. Many of these have existed in theory only, but to-day there is a prominent current saver which is rapidly becoming known and popular.

This includes the newer filament lamps all with filaments other than carbon. It has been ascertained by careful and painstaking experiments that these different filaments actually save current, furnishing the same amount of light with a smaller expenditure of electrical energy. In an automobile lighting system this is one of the biggest points to consider, therefore they are very well fitted to be used for this purpose, particularly now that they are constructed so as to be strong and rugged.

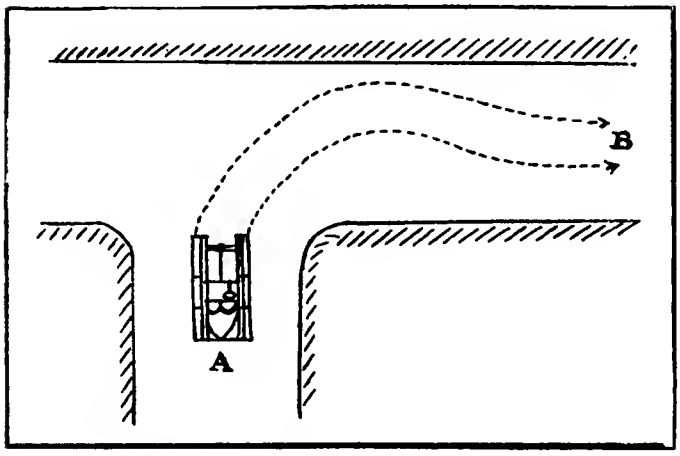
Particular reference is had to the tungsten lamps, which not only will give an equal amount of light with 60 per cent of the current expended in the case of carbon lamps, but in addition maintain this factor of economy for a longer time. The latter feature is as valuable as is the former, for a lamp which saved an equal amount of current, but had a very short life, would be a poor saving. In this contingency the extra cost of lamps and trouble of renewing would overbalance the saving in current.

As now made these tungsten lamps take on various forms, the filaments in particular assuming peculiar and fantastic shapes. Two of these are shown to illustrate this point, one having a number of coils or loops, while the other is made with a series of straight webs connecting an upper and lower ring.

Aids in the Driving of a Car — Part 3.

By D. R. Hobart

BREAKAGES of wheels and springs are in a large measure due to the fact that comparatively few autoists know how to properly make turns. In many instances breakages are directly traceable to cutting corners too sharply, either through a desire to save time or because of miscalculation on the part of the driver. Should a collision be the final result of the careless negotiation of a corner or turn, it is often the direct result of



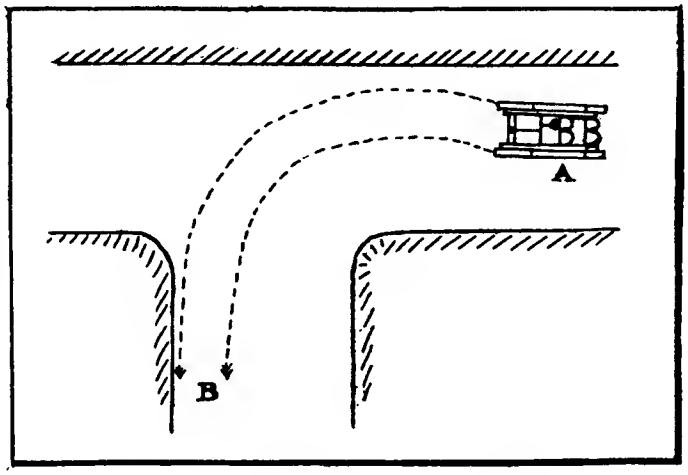
Proper Method of Making a Turn to the Right

ignorance of the proper amount of space that should be allowed for maneuvering the car, or what is even worse, utter indifference to anything that may happen to the car or to other users of the road. The negotiation of turns is a simple matter as far as the steering of the car is concerned, but experience is essential to the proper procedure under unusual circumstances, as when the road is partially obstructed by excavations, vehicles, etc. No rules can be laid down to cover all cases, but there are a number of things which should be borne in mind at all times with regard to turns.

Negotiating Turns—The procedure on approaching a turn is exactly similar to that on approaching a road crossing. The car should keep to the center of the road and its speed should be reduced somewhat until the road is seen to be clear when the turn can be made. In taking a right hand turn, the autoist should keep well away from the corner, describing as large an arc as possible and gradually gaining the center of the other road. Such maneuver is shown in the sketch, where the car A follows the dotted course until the point B is reached. By so doing a collision with another car coming in the opposite direction will be avoided as either car can swing clear. In taking a turn to the left a similar maneuver should be made, but in this case the car should keep close to the proper side, as in the sketch of the left turn. The size of the arc described in making the turn will, of course, depend on the width of the road and the length of the car, small runabouts being able to turn in an arc of 25 feet or less, while large touring cars should describe arcs of 32 feet and over on an ordinary road.

Corner Shaving to Be Avoided—Except when absolutely necessary to avoid a collision corners should never be cut closely or "shaved" as it is often called. By shaving a corner the autoist runs chances of colliding with other vehicles, and engenders a dislike in all other users of the road not only for himself but for automobiles in general. There are numbers of drivers that habitually shave corners, who start to make the turn before reaching the proper point and cut diagonally across the road, obstructing traffic coming in the opposite direction, and hugging the left hand corner of the intersecting road. Their desire is evidently to travel from one point to another in the shortest possible space of time, and to save distance cut the corners without regard to the rights or safety of others. The majority of automobile drivers of this class luckily confine their operations to city streets, although they are found in some numbers on country roads. On the other hand a large majority of horse drivers are corner shavers, women being particularly given to the practice. Because of the presence of this and the reckless classes of drivers, special caution has to be exercised at all times by those in charge of vehicles of every kind.

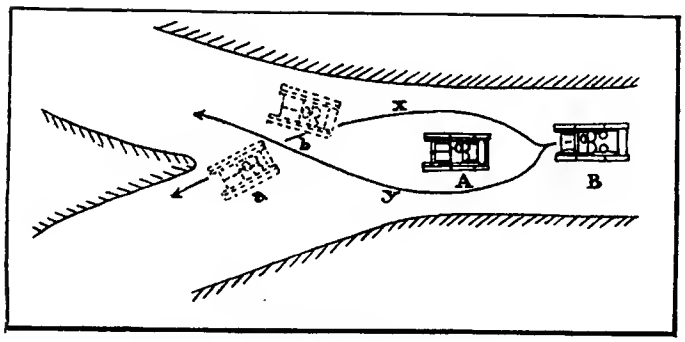
On Approaching a Road Fork—On approaching a point where the road forks or branches off, the autoist should hold well over to the proper side of the road in order to avoid cars coming along the branches. Should he be traveling along one of the branches toward the fork, however, he should keep in the center, as when approaching an ordinary turn. On overtaking another car, it would be better to allow the latter to proceed on its course without attempting to pass, unless the driver signals the direction he is about to take. The reason for this can be readily seen by referring to the sketch where car B is about to overtake car A. If B attempts to pass A by taking the path *y*, a collision will occur if car A turns down the left fork at *a*. On the other hand, if the path *x* on the wrong side is taken, a collision will occur at *b* if the leading car takes the right fork. Hence the driver of B should allow A to take its course before proceeding on his own. If the driver of car A should signal the fork he is going to take, B can pass on the proper side if the same fork is to be taken by both, and on the wrong side if



Course to Be Followed on Turning to Left

A is to take the left fork and B the right. If A is to take the right and B the left fork, B will pass in the ordinary manner.

Car Lines an Element of Danger to Autoists—Whether running in city or country, the autoist should be extremely careful regarding car—or as they are often called trolley—lines. Undoubtedly no other form of transportation on public roads con-



Passing a Car at a Fork of the Road

stitutes such a great source of danger to all other forms, particularly as localities in which the lines are located are those where traffic is above the average in volume. It is rare indeed that a trolley line is built on its own right of way; it usually occupies a good half of the common road and the autoist will frequently encounter the rails emerging from what seems to be a dense undergrowth or appearing suddenly from an adjoining road, its presence being only indicated beforehand by the overhead wire and its means of suspension. As a rule the line is laid on one side of the road, but there appears to be no generally recognized plan as regards location, and the autoist must keep a sharp lookout not only for surprising changes in location of the line but also for the cars themselves.

Track Should Be Carefully Watched—Regarding the track itself strict watch should be kept for rails which are elevated above the level of the road, for switch tongues and for differences in level between the bed of the line or track and the surface of the road. Any of the above may interfere with the steering of the automobile if the wheels come in contact with them, and if the road is at all greasy, side slips are likely to occur. The rails are a source of trouble when slippery and care should be taken that the tires do not get into the rail channels, as they will be badly wrenched or even torn off when a change of direction is desired. One of the commonest mistakes made is in running the car with all four tires in the channels, which undoubtedly makes smooth riding but which also renders it difficult for the autoist to steer out of them again when he wishes to do so by any movement of the steering gear. When the rails are dry, only a short time will elapse before the tire will ride over the rail-head and get clear, but with wet rails sometimes hundreds of feet are traversed before the tires are clear. Such a situation would not be rendered pleasanter if a car was seen approaching at speed along the track. Even when one tire enters a rail channel it is not easy to get it clear, especially if the tire is smooth or of small profile. The autoist should therefore keep clear of slippery rails and when crossing them do so at as great an angle as possible, dodging projecting track work and being ready to correct any action due to the catching or sliding of the tires. When there is no great difference in level between the bed of the line and the road surface the car may be driven with the right hand wheels between the rails and the left hand wheels clear, as shown in the sketch, so that the car may be swung clear if a trolley car be overtaken or if slow moving vehicles are to be passed. This method of running finds frequent employment on "trolley ridden" roads of narrow width and there is a good deal to be said in its favor.

Negotiating Trolley Cars—Owing to the fact that the trolley car runs over a fixed route and therefore cannot turn aside to avert a collision or follow a course best suited to the circumstances, the autoist must treat it as a distinctive sort of vehicle which has to be negotiated in a different manner from others. First he should remember that if there is sufficient space to pass the car there will continue to be sufficient space, but if there is not then something will get smashed. The redeeming feature lies in the fact that the rails and switches are distinct guides as to what course a trolley car will take. With other vehicles, the intentions of the driver can be ascertained by observing the direction he is taking, the speed at which he is traveling and his position with regard to others on the road, but with the trolley car the course being taken at the moment indicates nothing and the track ahead is that which should be watched. Particular care should be taken where the tracks change from one side of the road to the other, and cars usually take such portions of the track at the same speed as when on a straightaway, regardless of other vehicles on the road. As a rule trolley cars should be overtaken and passed, as explained in Part 2, where the track ahead is straight or where it is only on one side of the road. The autoist should never attempt to pass a trolley car when a curve, turnout or crossing is in sight, but follow it at the same speed that it is traveling until the way is clear on either side.* Passing should be done on the proper side except where the car is on the wrong side of the road, when the autoist should pass carefully on the wrong side, keeping well over to the right hand side of the road in so doing.

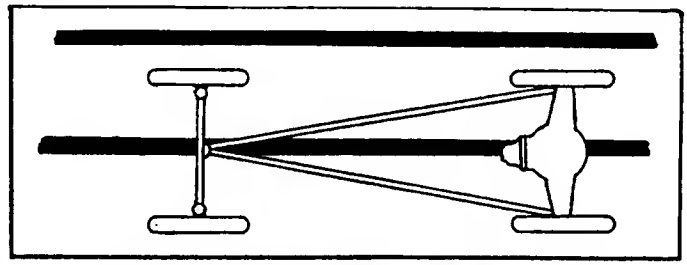
Crossing Railroad Tracks—All railroad tracks should be treated as if trains were likely to be due at the crossing at any moment and the car should be driven across at the greatest angle and at the best speed possible. A sharp lookout should be kept in both directions and the car slowed down on approaching the crossing, taking absolutely no chances whatsoever. In case a collision is imminent, the steering wheels should be turned sharply in the direction in which the train is moving so that the car will be struck a glancing blow and the occupants will have some chance of escape.

Experience Necessary in Evading Side Slips and Skids—Nothing but actual experience can teach the autoist how to evade the ever-present bogey of side slip when the roads are in a slippery state. He may be forewarned of the various kinds of side slips and skids and the proper procedure under the circumstances, but he must actually experience each kind in order to distinguish one from the other and to acquire the instinct necessary to counterbalance every tendency in that direction immediately the first symptoms are perceptible. There are certain kinds of surface on which the tires cannot obtain a firm grip, places in which sideways strains are brought to bear on the car, and acts on the part of the driver which either reduce or increase the adherence between the tires and the road. These three things are unconsciously or consciously learned by every autoist of any road experience and those not familiar with them will do well to find out all that is possible concerning these points before venturing on slippery roads.

Skidding to Be Distinguished from Side Slip—Although both the terms skidding and side slipping are used freely as regards automobiling, their meanings are often confused and the former is used to designate both. Skidding implies a continued forward movement of the car or vehicle after the wheels have been retarded or locked by the brakes; while side slipping relates only to a lateral motion of the car due to the wheels sliding bodily sideways. Practically, the distinction between the two is not so sharply drawn, as skidding is of comparatively rare occurrence and usually develops into side slip automatically.

To the inexperienced autoist, side slips which should be skids in his opinion, are apt to prove very disconcerting.

(To be concluded.)



When Running Lengthwise of Street Car Tracks

Letters Interesting and Instructive

THE SUBJECT OF WEIGHTS

Editor THE AUTOMOBILE:

[1,897]—Being a subscriber to "The Automobile," I would like to have you inform me of the weight of front and rear wheels, including tires on machines carrying from four to seven passengers. That is, I wish to obtain the weight on the ordinary car as well as on the heavy touring car. Is there a list of such weights and cars?
Boston, Mass. HENRY HASTINGS.

It is hard to decide whether you mean weight of wheels or weight on wheels. In case it is the latter, you will find in the May 20 issue of THE AUTOMOBILE, page 810, the tabular weights of the cars in the one-gallon test. These represent accurately the weights of both cars and passengers in ordinary touring conditions, and you will find therein cars of all classes from the fast six-cylinder runabout with three passengers to the larger four and six-cylinder touring cars with a full complement of five or seven people.

To get more exactly the weight distribution on the front and rear wheels, it will be necessary to give you the information from cars with which we are familiar as there is no available data on this subject. Thus the Apperson car, with a four-passenger body, weighs exactly 3,100 pounds, of which 1,493 are carried on the front wheels, and 1,607 on the rear wheels, making the car 114 pounds out of an exact balance. The Simplex 30 is only 56 pounds out of balance, as the total weight of 2,914 pounds, with a tonneau, is divided 1,429 to the front wheels and 1,485 to the rear wheels. These are the only cars of which this data is immediately available.

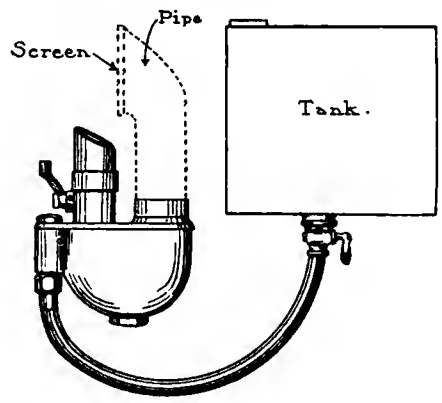
In case you mean weight of the wheels themselves, this also is a subject on which exact data is not available, but for very general purposes you would be safe in figuring it at from 30 to 75 pounds per wheel, including tire. The former figure will be safe as the lower limit for small light wheels with corresponding tires, such as ten-spoke wheels with 28 by 3 tires. The other figures will answer for the heaviest practice, such as fourteen-spoke wheels with 36 by 5½ tires.

TROUBLE WITH AIR INTAKE

Editor THE AUTOMOBILE:

[1,898]—I have a ———— carbureter on my runabout and the air intake is near the gasoline tank. On going up grades, the fuel runs out of the vent in the tank cap, down into the carbureter air intake. Could I put a strainer on it to take air from the side away from the tank, or would a flat strainer on top of the carbureter be better? Please advise me also where I can procure a brass strainer of the kind needed for this purpose. C. VEEDER.
Rosendale, N. Y.

The addition of fuel as you describe to the air at the air inlet will seriously disturb the running of the engine and probably give so rich a mixture as to choke the engine. It is advisable to remedy this at once, and the best way to do this is to prolong the present air inlet upwards and outwards away from the gasoline tank which causes the trouble. To do this, have a sort of stove pipe made; it may be of galvanized iron, tin or any similar metal. Have this made long enough to take the top very near to the top of the offending tank, then a big, easy bend away from the latter. The opening or mouth of the pipe should be so formed as to take a screen, which is necessary to keep out the dust, and should preferably be made removable, so that when the screen clogs with dust it can be taken off, cleaned, and replaced.. For this purpose use a very fine



Sketch of New Air Intake

brass gauze, which you can obtain at any hardware store, and for a small cost.

In the appended sketch is shown a rough diagram as your case is understood and in dotted lines the suggested improvement.

SHORT VALVE STEMS

Editor THE AUTOMOBILE:

[1,899]—I have a Mercedes 18-22 horsepower car. The last time I had the engine overhauled some of the valves were ground in too much, which lets the exhaust valve stems come very close to the lifts when they are down. And the next time they are ground the valves will probably not seat. Is it the proper practice to file a little off the end of the valve stems? How will this affect the turning of the valves?
Rowlandville, Md. EDWARD CONNER.

The answer to your question is no, it is not proper practice to file off the ends of the valve stems. You are worrying over trouble which has not made its appearance yet, but when the next regrinding is done you will know for sure. If the case you describe comes true, take the valves to a shop noted for good work, have the temper drawn from the valve stem ends (they are usually hardened), and have about twice as much as is necessary turned off from the ends in a lathe. The extra amount is to allow for another grinding of the valves, or perhaps it would be better to have about an eighth of an inch taken off, which will provide for a large number of regrindings.

Next, the end of the stem must be carefully hardened again, and this is no ordinary job, for when it is finished the end must be straight and square with the axis of the whole valve. If this is not true, the action of the push rod will tend to throw the valve off to one side (the side which is high) and make the work of grinding for nothing.

Providing that the clearance between the push rod and the end of the valve is kept the same, by means of the adjustment provided, it is hard to see how any alteration in the length will alter the timing of the valves. Before making the changes suggested it would be well to measure this clearance, carefully remembering that it usually is but a few thousandths of an inch.

It would also be well to measure the amount of possible adjustment provided, and shorten your valve by an amount less than this, for if you shortened more than the adjustment the clearance would be increased, and the whole timing thrown out.

ABILITY OF MAGNETO SPARK

Editor THE AUTOMOBILE:

[1,900]—Will you kindly advise me on the following points: I have a four-year-old car, which is now in need of an overhauling. The ignition is by means of two sets of dry cells, four each, working through a coil. The engine is of very high compression. Last year the dry cells required frequent renewals, and now I am considering the installation of a magneto. The question with me is, would it be possible to start on the magneto alone with such high compression? Also, I have just put on a new set of piston rings; can this be the cause of the engine overheating badly, whereas formerly it never did. The water circulation seems to be good, also the cylinder oil feed, yet it heats, therefore it has neither speed nor power. F. K. G.
Louisville, Ky.

The number of cells supplied with the car were evidently too few or they would not have required as you say "frequent renewals." If you care to try dry cells again, use either eight or twelve, connected up in series-multiple, as described in the March 4 issue of THE AUTOMOBILE, and enlarged upon in much detail in the issue of May 20, pages 817 and 818.

In case you do not want to try them again, the installation of a magneto will be a perfectly safe thing to do even in view of the high compression of which you speak, but of which you do not give the exact figure. The magneto, as now marketed, will give a spark strong enough to ignite any charge, no matter how much the compression is, at the ordinary speed of cranking. If this were not so, the racing machines, some of them with a compression of 110 pounds, which is undoubtedly much more than you have, would not be equipped with single ignition, and with a magneto as the source of power.

High compression has also something to do with the overheating of your engine, which is doubtless due to the new rings not being fitted to the cylinder. Until this condition obtains, it will continue to heat. You can, however, help matters along by flooding the cylinders with oil until the rings are well ground into place. Probably a good rule to follow would be to double your usual cylinder lubrication, that is, the number of drops per minute. If the engine was of lower compression, it would not heat so readily even with new rings, which were of a larger diameter than the old ones. In the meantime, that is, while the rings, copiously oiled, are running themselves in, let the engine run as hot as it will, up to the point of actually seizing.

TIMING AN OLD ENGINE

Editor THE AUTOMOBILE:

[1,901]—Will you please tell me how to time an old engine, that is, one which does not have the different points marked upon the flywheel for a guide? C. G. FISHER.
Detroit, Mich.

On an engine old enough to date back to the period when the timing was not marked upon the surface of the flywheel take out the pet-cocks, or it will suffice to take out a single one. Then insert into that cylinder a scale or ruler, if the opening is large enough, and a piece of wire, if it happens that the hole is very small.

Turn the engine over very slowly by hand and carefully determine the upper and lower dead centers, as indicated on the rule or wire. These are indicated by the piston, and consequently, the rule, reaching the highest position and starting to go down again, in the case of the upper center, or reaching the bottom and starting up, in the case of the lower center. Mark these positions on the wire, or with the more convenient rule, note the exact point or dimension where they occur.

Now having determined the two dead centers, so that you can stop exactly at those points, you can proceed with the timing. First, it will be necessary to determine the timing which you wish to obtain, and this had better be the same as the makers of the engine intended or else you will have to have new cams made, which will be rather expensive.

Let us suppose that the cams are made to conform with the cycle which has been given in these columns several times lately, namely, inlet opens at 8 degrees past the upper center, closes at 26 past the lower center; exhaust opens at 46 before lower center, and closes at 5 past the upper. Now these angles mean little to you unless you are able to support the engine without the lower half of the crankcase, thus exposing the crankshaft, on which the angles should be measured. If you are not able to thus measure the angles directly upon the main shaft, you will have to transform them into inches of piston movement, which can be very readily measured.

To do this you must figure these points out, as you do not give the size of your engine so that we could figure it out for you. In case you have a table of natural functions, this is an easy matter. Thus, let A be the length of the connecting rod, B the radius of the crank circle or half the stroke, a the angle included between the axis of the engine and the crank, which will be the angle given above at the upper center, and 180 minus the one given above for the lower center. Now then we wish from these three quantities to find the other side of a triangle formed by the crank, connecting rod, and the axis. Call this other side C. Then the first formula to use is:

$$\sin b = \frac{B \sin a}{A}$$

From this, the second angle is found by substituting for a the four angles given, remembering that for the two cases of the lower center, the angle to be used is 180 minus those given.

Now having two angles and two sides the third side is obtained using:

$$C = A \cos b + B \cos a.$$

Add the length B, and the connecting rod length A. From this total, subtract the quantity just found, or C.

The result will be the amount that the piston or the rule will be away from center, when the desired angle is reached. By measuring off these amounts on the measuring device, you have but to turn the crank over slowly until these points are reached, when the piston is in the right position for setting the cam.

To show you how easy the calculation goes, one of the distances will be worked out. Suppose a 5½ by 6 engine with a 12-inch connecting rod. Then A equals 12, and B is half of 6 or 3. Take the inlet opening, 8 degrees past center, for example. the sine of 8 degrees is .14, then in the first formula:

$$\sin b = \frac{3 \times .14}{12} = .035,$$ then B equals 2 deg.

Now in the second formula:

$C = 12 \times .9994 + 3 \times .9903,$

then C equals 14.963 inches.

Subtracting this from the radius plus the length of the rod or 15 inches, the distance obtained is .037 inch, the amount the piston will move down for an angle of 8 degrees past upper center.

WOOD FOR FRAMES

Editor THE AUTOMOBILE:

[1,902]—Will you please give me some idea of the form of construction used with wood side frames, that is, how is the wood used and put together for this purpose?
Churchtown, N. J. D. DE V. WOOD.

One form of wood frame used in a popular make of car consists of three layers of selected second-growth white ash. These are so selected that the grain in each one runs in a different direction. They are sized and prepared for use, then glued together, after which they are screwed. In addition, a top and bottom piece with the grain running in a way to shed moisture are added for protection.

MORE AMPERE DIFFERENTIAL

Editor THE AUTOMOBILE:

[1,903]—Regarding the article on the Ampere car in a recent issue of your paper, will you please inform me through "Letters Interesting and Instructive" if I am right in my understanding that the rear wheels are thrown out of circuit, and thus disconnected, when the brakes are applied?
New York City. C. L. MOHR.

If you will look at the answer to R. C. Jordan in the issue of THE AUTOMOBILE for May 27 (1892), you will probably find a partial answer to your question; at least the subject of the differential action is there explained. As to the rest of your question the left foot pedal, corresponding to the clutch on an ordinary car, when pushed forward, as if to throw out the clutch, cuts off the current to the clutches in the transmission, which really take the place of the master clutch in the flywheel.

Similarly, with the right pedal operating the rear hub brakes, it is our understanding that this only applies the brakes as in the ordinary car, and has no other action upon the car or its action, nor is it interconnected with the clutch pedal, which does influence the current.

As the present understanding, it is not a fact that the current is disturbed in the rear hubs, except as brought out in the answer to Jordan, namely, when the steering gear is turned so as to turn the wheels at least 15 degrees out of a straight ahead line. That is, the answer to your question is no, the application of the brakes does not cut off the current to the rear wheels.

HARDENING COPPER

Editor THE AUTOMOBILE:

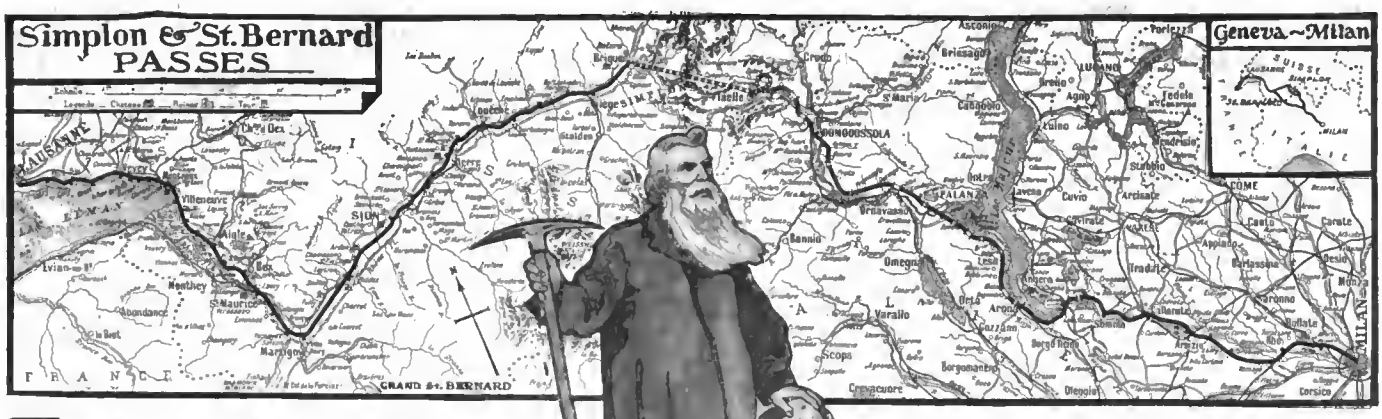
[1,904]—Is there any process by which pure copper in the form of tubing or sheets can be hardened or toughened so as to allow of its use in places where the softness would be objectionable? If there is any such process, will you kindly give me the details of it. C. G. DAY.
Belleville, Kansas.

There is no known process which can be used on the metal as turned out from the mills, without altering its condition. If you have facilities for melting and repouring into the desired shape, the following receipt will be of service to you:

For every 40 pounds of copper to be hardened, take 2 pounds of alum and 8 ounces of arsenic. Mix the alum and arsenic together, and after melting the copper in a crucible, add the mixture slowly, stirring the whole thoroughly. After the molten mixture has been stirred for at least five minutes, it is ready to pour.

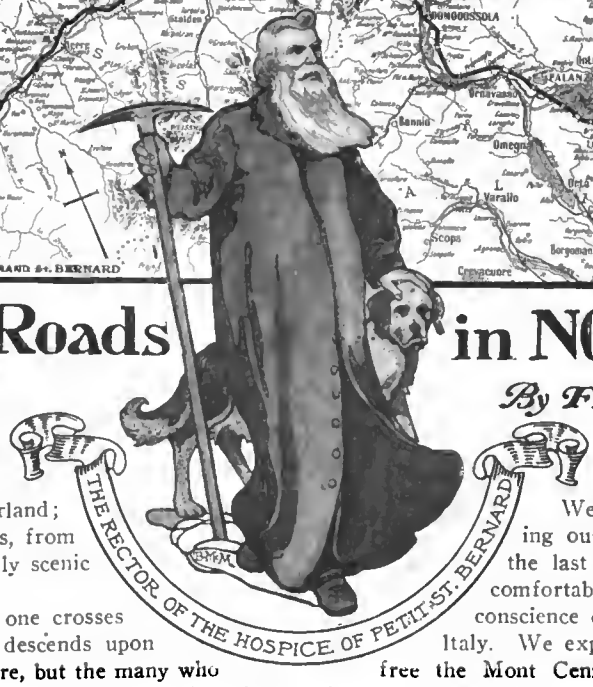
Copper treated in this way may be melted and remelted many times without injury or noticeable change in the composition. In addition, it may be rolled or drawn any number of times without injury. The alum and arsenic impart great density, toughness and hardness to the otherwise soft metal.

With a proof of the everyday use of this process by the average owner of an automobile, the mechanical world as a whole will be much the gainer. Copper is a valuable metal and its price restricts its use to certain parts, but softness has restricted it even more than price.



Automobile Roads in NORTH ITALY

By FRANCIS MILTOUN



THE three most commonly used mountain gateways into Italy are those over the Simplon, by Domodossola from Switzerland; over the Saint Bernard, by Aosta from Switzerland; or over Mont Genèvre or Mont Cenis, from France, via Susa. The most splendidly scenic of all is that over the Simplon.

The sudden apparition of Italy as one crosses the Alps by the Simplon Pass and descends upon Domodossola has been remarked before, but the many who now make the journey by road for the first time are bound to (hundreds to-day do it by automobile where scores did it by carriage in the days gone by) appreciate the same emotions as did travelers of old. Nothing is changed in general aspect, and the magic of the transformation from the forest-grown or glacier-peopled mountain sides of Switzerland to the sweet, smiling plains of Italy is a thing not to be justly described by any pen or adequately painted by any brush. No, nor can the kodakist, even, catch the mood; he indeed comes off worst of all. It is a thing to experience by one's senses. The emotions are purely personal ones, as those who have been here can attest.

Let rushing tourists who do the thing in four hours take to heart the experiences of Dom Bourdin, the Benedictine monk of the sixteenth century, who took three days to make the crossing. Frontier and passport regulations are lenient now, but the old monk in his day was held in durance vile for three rounds of the clock by the Spanish governor, who held the pass because the good man would not admit that his native land, the Franche-Comté, might not some day become Spanish. He said simply: "God puts crowns where he pleases; it is not for me to say who shall rule my land." This was a philosophical answer, and he held to it for three days, when the bombast official seeing finally that the brother would not give in passed him over. Verily, it would be folly to sigh for "the good old days."

From Turin the shortest and quickest way into France is via the dull, ancient town of Susa and the Col du Mont Genèvre, descending on Briançon: or by Mont Cenis, coming down to low level at Modane. There is not much to choose between them except that the last-named pass is apt to be closed by snow and ice as late as the first of June, whereas that by Mont Genèvre is usually kept open through the winter.

One leaves Turin and its gracious streets and boulevards by the gently rising Strada di Francia, thirty odd kilometers, to Susa, the ancient Segusium of the Roman empire. We anticipated nothing difficult in making our way out of Italy on this occasion, the last week in May, and we rolled along comfortably enough and with an easy mind and conscience over the best roads we had found in Italy. We expected to stay the night at Susa and free the Mont Cenis in the morning. We stayed the night at the exceedingly primitive Albergo del Sola at Susa, but learned that the snows of winter were still lingering a meter deep *en haut*, so other plans were to be made. It was a case of crossing by Mont Genèvre, with its less beautifully graded road (some hills, in fact, grading 17 per cent.). We recalled the fact that Dante the wayfarer crossed over into France by this road centuries ago, and surely a modern automobile could make easy work of it. The traveler by automobile, too, may well repeat Dante's words: *"Come di nive in Alpe senza vento."*

The road over the Col du Mont Cenis, 28 kilometers above Susa, has been used since time immemorial, though the present carriage road over which automobilists crawl up or down (over the magnificent "Scala") has existed only since 1812. Its elevation, of 2,080 meters, is the lowest of any of the Alpine passes into Italy, save that of its neighbor over Mont Genèvre, which is slightly less, but equally productive of superb scenery.

We had intended entering France via Modane and returning north via Grenoble, but, owing to the dilatoriness of the season, we were forced to make a 300-kilometer detour through Briançon, Embrun and Gap, for even the Col du Lautret in France was still snowbound, and snow means impassability here.

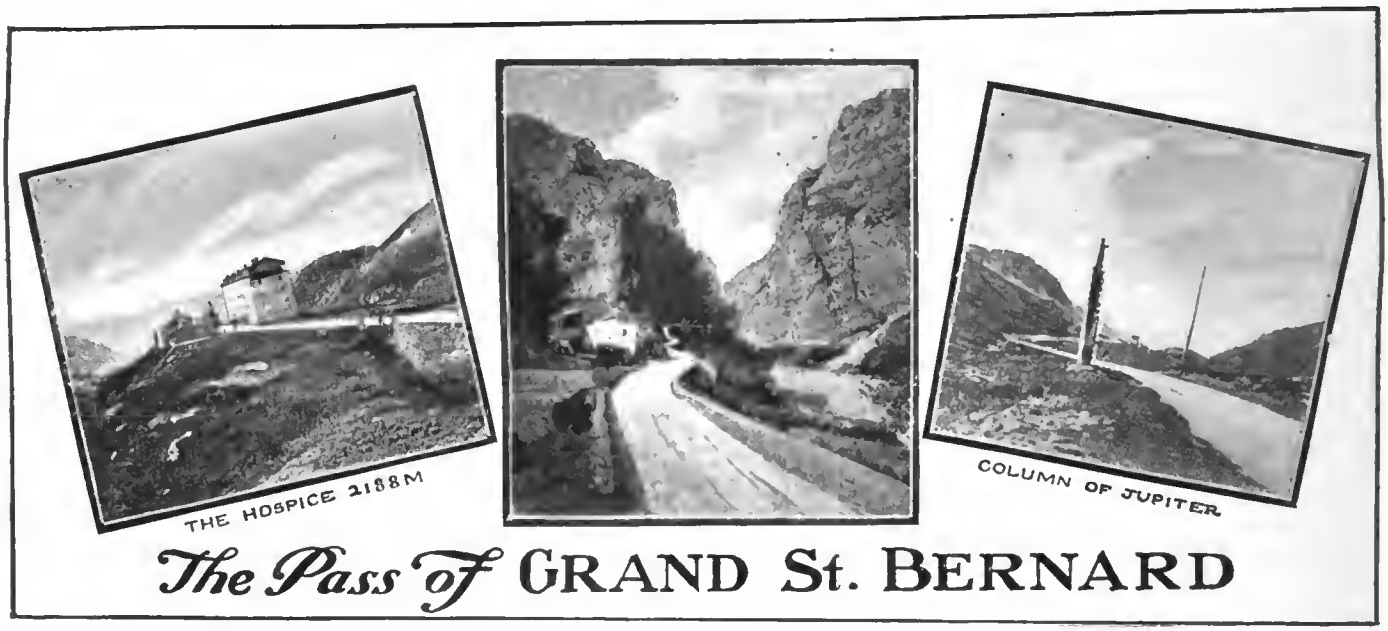
On leaving Susa via Mont Genèvre one meets the stiffest five kilometers on the itinerary immediately on leaving the town. For some inexplicable reason, unless it was the direct capriciousness of Beelzebub, we could do literally nothing on this five kilometers just outside of Susa, and spent a day and another night finding out that nothing was the matter; that the piston had not gripped or a bearing fired; and that it was simply a good-sized pebble that had got wedged in between the flywheel and the engine casing, preventing the motor from "spinning" or even turning over on itself. It was one of those things that ought not to have delayed us for a moment, of course, so simple

The Salle à Manger Garage at Novara

it was to solve. But it did, all the same. Have you, dear reader, and accomplished motorist, ever met exactly the same thing? No; nor the writer, either; not before this occasion, and we were accordingly puzzled. Sometimes we are not so auto-wise as we think we are, or, at least, would like to believe.

Finally, at daybreak on the second morning, we set out to cover the 55 kilometers between Susa in Italy and Briançon in France. Take it on the whole it was a hard rise all the way along, though it leveled down to between 6 and 8 per cent. after Oulx. A ruined fortress, La Brunetta, once the key to the whole valley, sits high above Susa, and is still something more than a memory. With Exilles and Fenestrelles it formed the fortified frontier between Piedmont and France. Hannibal is supposed to have crossed the Alps via this road and to have urged his jaded men to climb the Monte di Roccia, 3,000 meters above Susa, that they might be encouraged by the sight of the rich Lombard plains stretching out before them.

The Mont Genèvre road was built when Cottius submitted to Augustus. Beyond Susa it branches to the left, whilst that



The Pass of GRAND St. BERNARD

over Mont Cenis leads to the right. That over Mont Genèvre was the most frequented of all Roman roads between Italy and Cisalpine Gaul. The military road of Pompey and Cæsar passed through Oulx and over the Col de Sestrières.

Via Mont Cenis the Italian *dogana* for fixing up one's papers is at Bard and the French *douane* at Lans-le-Bourg.

Via Mont Genèvre, Claviers and La Vachette, ten kilometers apart, perform the same functions, one on the Italian slope and the other in France, the actual crossing of the frontier being at an elevation of 1,860 meters.

From Milan westward the best sortie on France is via the Val d'Aoste and the petit Saint Bernard, say, 200 kilometers to Aosta, where the road divides, one section leading to Switzerland over the Grand Saint Bernard and the other via its little namesake into France via Moutiers and Albertville.

We had done this thing in times past, but on the present occasion it was too early in the season and it was for that reason we had turned to Turin.

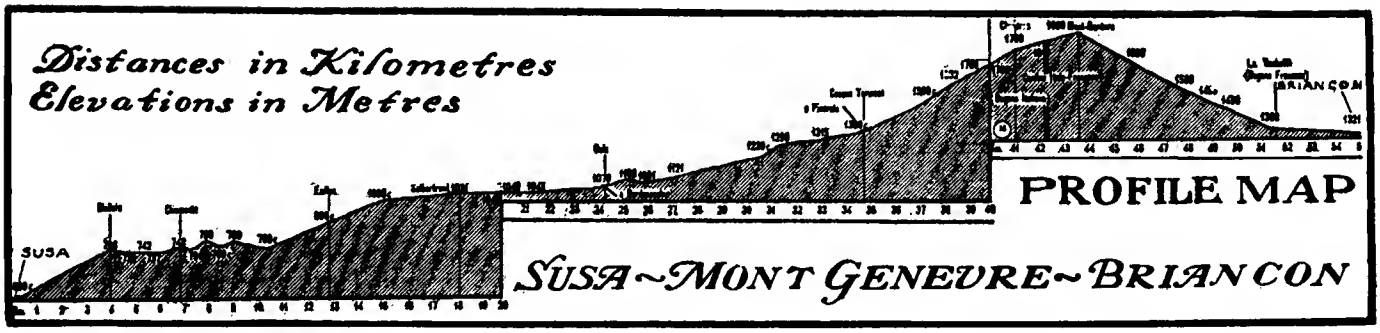
Milan is monumental from every point of view, from its cathedral to its restaurants, hotels and garages, and its streets, though mostly paved with great granite blocks, are a delight to ride over by reasons of the flat flags set down in the middle. They can only be compared to the famous "iron roads" of certain sections of New Jersey a few generations ago, which, if they still exist, must be a dream to the modern automobilist.

At Novarra we put for the night at the French-named Hôtel de la Ville. It was not bad at all, but dear; the dinner was the best we had eaten in all Italy, and was priced accordingly. No garage accommodations were forthcoming, though the proprietor claimed to having room for a dozen automobiles. Well, he had—in the dining-room; that was where we put ours, and it wasn't a bad garage, either, as one may judge from the accompanying illustration. Novarra looks more like a French town than it does an Italian one, though a *salle à manger* garage is distinctly Italian, if it is anything.

Going out from Turin we fell in with a party of scouting motorcyclist soldiers of King Victor Emanuel, something of a novelty to an American who knows only the New York bicycle cop. The Italian army, like many other Italian institutions, is very modern. A series of recent maneuvers in the high Alpine valleys developed this entirely new type of soldier. Certainly the speed and economy with which the motorcycle can transport its bearer over roads entirely unsuitable for four-wheeled traffic makes its future assured for this class of soldiering. The horse is nowhere fit for this class of work. Imagine a powerful motorcycle carrying its rider up 15 per cent. mountain roads thick with dust and stony at that. Where the average horse can find a foothold so, too, can a motorcycle find a wheel track, and it does not lie down on the job through fatigue as does the quadruped. It may be hid in a thicket or behind a boulder and its soldier scout may climb some neighboring vantage point and scan the horizon for miles without fear that his steed will neigh, whinney or bolt. Avanti! has ever been the watchword of the Italian army, and it is a good one. Another entry from North Italy into France, though by no means a usual one, though we found it most interesting on a certain occasion, and, in fact, the only one to be considered for a moment if time and distance are to be taken note of in going from the Riviera to the Italian lakes is that via Cuneo and the Col de Tende.

This itinerary surveys the road from Turin to the Mediterranean, but there are no radical changes in making it in the opposite direction save in the reversed order of things.

Twenty kilometers from Turin is Carignano, with a storied past and famous for the beauty of its places of worship and its women. The church of Santa Maria della Grazie was the annex of a monastery of Franciscan friars, and was endowed by the Duchess Bianca, the wife of Charles I., whose monument it contains. She was one of the first of Carignano's ladies of surpassing beauty, and for that and her *"gentilezza"* the Chevalier Bayard, who had been brought up in the household of the duke, did his best to win a tournament which was being held in her honor on a certain occasion. He did win; that goes without saying of so chevalieresque a man.



Ten kilometers to the right beyond Carignano is Carmagnola. The women of Carmagnola possess a specious grace and beauty like those of Carignano which have gone down into history. A ravishing dancer of Paris in the days of the Citizen King was a lady known as "Carmagnola," and her specialty, besides breaking beaux hearts, was the dancing of the "carmagnole," which had its origin here, although the Marseillais think it is theirs. By what right they assume this it is hard to reason out, though the Savoyards, who made up a part of the famous "Marseilles Battalion" which marched on Paris to help capture the king's castle in revolutionary days, may have come from here. The female youth and beauty of Carmagnola dresses itself up with gay headdresses and strings of glass beads on the least provocation, and dances the carmagnole with a fervor only equaled by the Spanish senorita when she works hard at reeling off that barbaric series of convulsions which go with a pair of castanets and a loosely girt waistline. The two may, indeed, be related.

Still on towards the French frontier, ten kilometers more, and another beauty show is offered one at Racconigi. Maybe all the women of these parts are beautiful, the writer had perhaps best say so and be done with it. Here, at any rate, they are different from the ladies of the glass beads and the fierce contortions at Carmagnola, only a few minutes away. Besides its beautiful women Racconigi has a remarkable country castle or palace built by Palagi, "one of the most comfortable of the country houses of Piedmont," said a traveler of two centuries ago who had been invited thither.

Two castles and a fortification wall once surrounded Cavaller Maggiore, another dozen of kilometers farther on, but nothing but a badly paved street, some indifferent stone houses with overhanging eaves of tile or brick, and two grim half-tumbled walls will recall the pompously named little town to the automobilist once he has passed through. It is the dullest, deadest town of five thousand inhabitants in all Italy.

Savigliano is printed in slightly larger letters on the maps, and is honored by being noted down as a railway junction. Formerly fortified, it has no monuments of interest to-day save a great triumphal arch erected in honor of the marriage of Victor Amadeo and Christine of France.

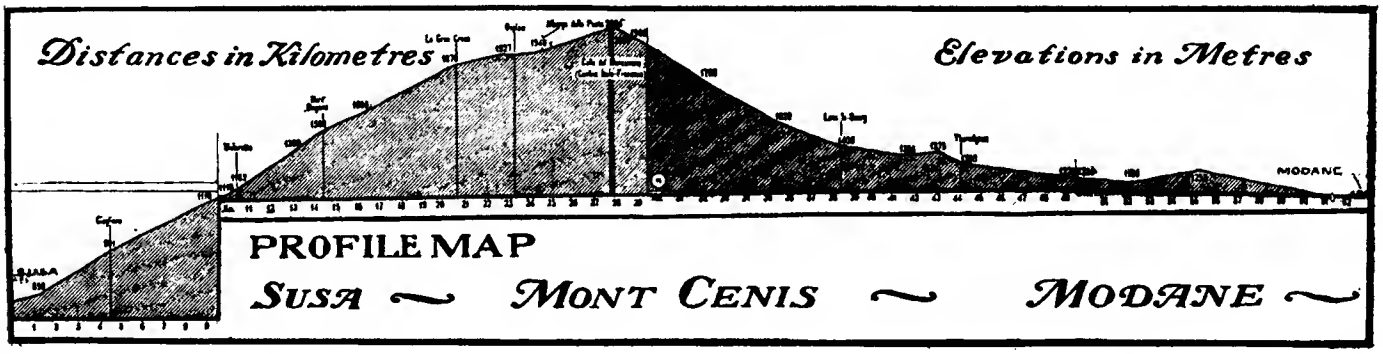
Thirteen kilometers to the right is Saluzzo, the capital of the Marquises, who played the game of war in northern Italy so successfully in the fifteenth century that they very nearly became lords of all the region. Saluzzo was the birthplace of Pellico, the author of "Francesco da Rimini," who got ten years' imprisonment as a result of too great a display of his patriotism by means of his talent. He is not a prophet without honor.

Cuneo to-day, in Italian, or Coni, in French, is a live, bustling place of 30,000 souls, who live by most of the industries which occupy the modern hand and mind. In the old days it was different. Cuneo originally was a place of refuge when Boniface, Marquis of Savoy, sought to oppress the people and made the other neighboring lords of castles do the same. As a blind the people assembled one day in the year 1100, supposedly as if on a pilgrimage to the Madonna del Bosco, a celebrated shrine of the neighborhood, determined to revenge themselves on the insults which had for long been cast upon their women folk by neighboring nobles. So successful a demonstration was made that many neighboring castles were razed, and the people, retreating to the peninsula-like small piece of land between the two rivers, started to build a city—the *"nuova villa di Cuneo,"* as it was called by the Abbot of San Dalmazzo in his chronicle.

Afterwards Cuneo was one of the most celebrated military strongholds of Piedmont, and only after the battle of Marengo, when the three consuls decided to raze the walls of Cuneo, Milan and Tortona, was it shorn of its powers.

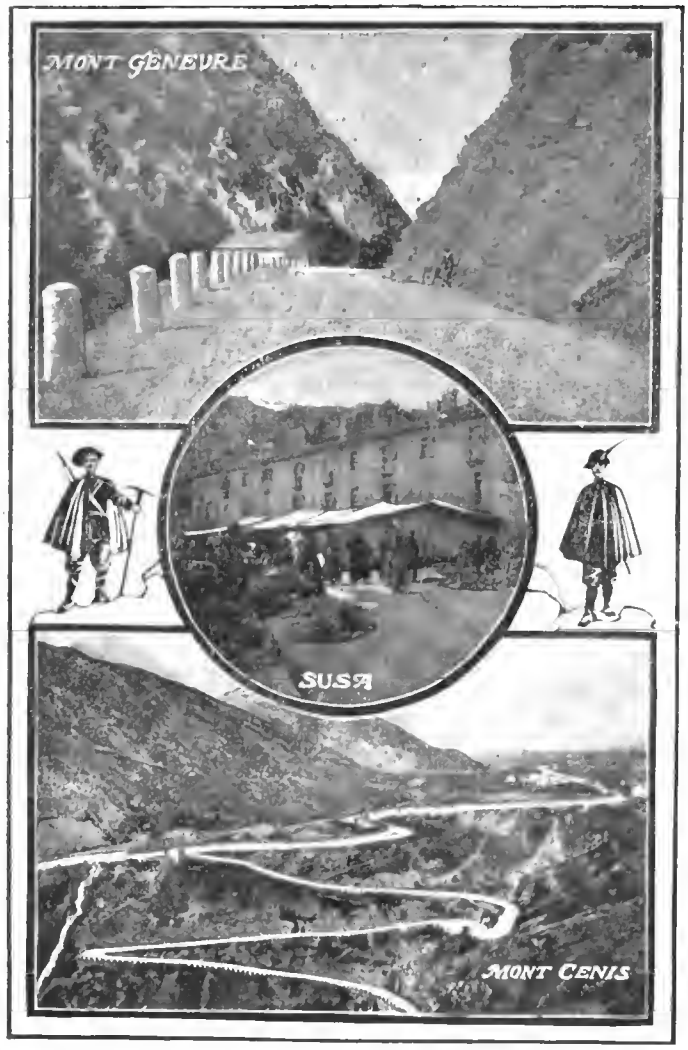
From Cuneo to the frontier the high road climbs gradually up towards the crest at the Col de Tende, the easiest of all the mountain roads in and out of Italy. At San Dalmazzo, a decayed and almost deserted burg, nearly wiped off the earth by the Milanese in 1250, is the Italian customs house, or *dogana*, where the automobilist and all other travelers by road pay tribute on entering Italy from France, and where those going towards France had best begin to get ready for the same operation a little further on.

The great plains of Piedmont and Lombardy are now far behind, though they may be seen still spreading out into the interminable distance. Now one begins literally to climb for the mass of the Maritime Alps of France and Italy are truly noble. Mont Viso raises its crest nearly 4,000 meters, and a typical Alpine road, though perhaps not the best that ever was, turns and twists its way in lacets until near the top one passes a deserted half-attempted tunnel which was supposed to cut off the climb somewhat. The road goes on, however, for several kilometers farther before the pass is actually reached, and the three kilometer tunnel remains as nothing but a fairy-like project which never came into being.



The Col di Tende, the pass where the road drops down on to French soil, is a bad enough place to pass in a gale or a snow storm, for the elements rage here with a fury which has been known to blow horses and mules and carts and men down into the ravine below. Otherwise the road is ranked as a grande route both in France and Italy, and accordingly practicable to automobile or any other wheeled traffic.

On the French side the road descends in seventy odd zigzags to Tende, at the foot of the Col. The soil is still Italian, and in feudal times Tende played no inconsiderable part. There are some remains of an old castle, and history says that Beatrice di Tenda, the wife of its old-time chatelain, was by her lord's aroders tortured to death, so that's something to impress Tende on the mind.



This roadway of the Col de Tende was begun by Carlo Emanuel I., in 1591, and down through successive eras it has ever been improved. It now runs in tumbling, rollicking fashion beside the torrent of the Roya, with little eagle's-nest villages clinging to the cliffs in one side and the rushing waters boiling close on the other. Through the Gorge de Borghe one passes through a defile which is a worthy rival of the Gorge de Pierre Lys in the Pyrenees.

Throughout this region there is a strong mixture of French and Italian that one can hardly tell where one begins and the other leaves off.

The first French village is struck at a level of approximately 300 meters. Giandola is its name, but that is about all one will remember of it.

Sospel is better. It sits in a panoramic site surrounded by gently rising and rounded peaks, and its immediate environs, laid out with olive groves and vineyards, after the unmistakable Riviera background towns all the way from Toulon to Menton.

The valley now becomes very fertile and the road winds less rudely and savagely as it descends gently to sea level at Nice.

A distinctly curious and interesting industry roundabout is the making of flower essences, notably orange flower water and lavender water. It is the most productive source of income to a country maiden with industrious habits, and with its proceeds she buys to-day "Bon Marché" finery instead of sticking to the picturesque old Niçois costume of a short skirt, a bright fichu and a pancake or crèpe hat such as Fragonard painted in pictures. Frangonard, by the way, was born at Grasse, so he came by the knowledge of the type naturally.

A road branches off from Sospel to Menton by the Col de Castig lione, at a height of 800 meters, and the road is every bit as attractive as that direct into Nice.

From Sospel to Nice direct the road begins to climb immediately one leaves his hotel door, and goes on climbing until it gets eleven or twelve hundred meters above the sea, from whence it drops down as precipitately to the Promenade des Anglais.

GOOD FIELD FOR SALES IN MEXICO

Consul Lewis A. Martin submits the following report on the use of automobiles in the Mexican district of Chihuahua:

Automobiles have been much in evidence in this city during the year past. They are as yet used principally for pleasure, but it is probable that they soon may be used for the delivery of goods and for conveying passengers. A Michigan company has an agency in this city and has sold quite a number of its machines here. There are a few other machines in use, but the great majority of automobiles seen here are of one manufacture. Some months ago there were eighteen automobiles destroyed in a fire which burned the garage where many private machines were stored. A few were rescued, but most of the machines were consumed before the fire could be controlled. This disaster leaves an opening for the sale of as many more. The machines here are used by professional men and by gentlemen interested in mines who live in the city, as well as by persons with means who use them for pleasure.

There are in this city quite a number of wealthy Mexican families who are able to own the very best make of automobiles and they do not care for the price of such things. They like the best and most luxurious conveyances. The most of these people are supplied with fine carriages and beautiful spans of horses, but the keeping of horses in this city is very expensive, and it is understood that the automobile is more economical. There is no competition here in the automobile trade. All those in use are American-built machines and, with few exceptions, all were sold by the Michigan company, no other manufacturer being represented in this city. The type for which a demand could be created here is a light-weight, low-price car, requiring a small amount for upkeep, the roads in this section being hilly and rough and very hard on tires and parts liable to breakage.

APRIL IMPORTS SHOW BIG INCREASE

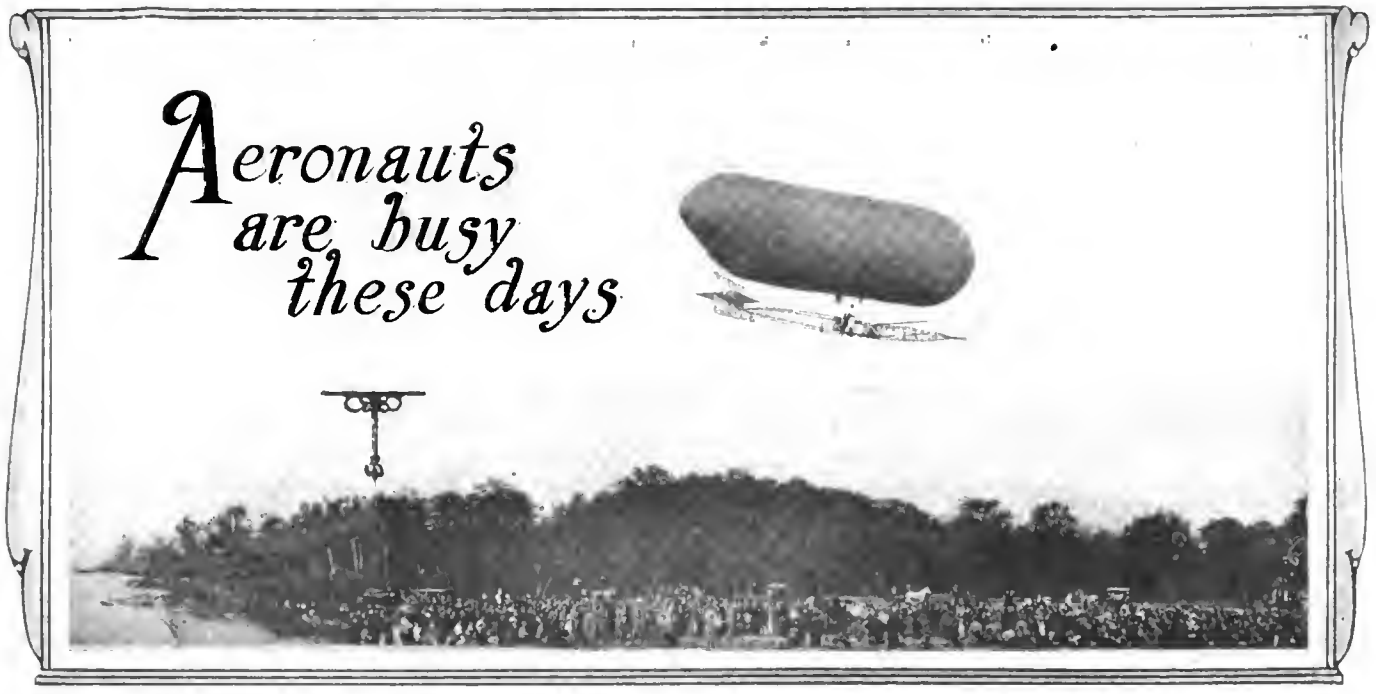
The monthly summary of the Department of Commerce and Labor shows that for the month of April 185 automobiles were imported of a value of $312,159 as compared with 58 valued at $148,603 for the corresponding period of 1908. This, added to previous imports, brings the total for the ten months up to 1,300 machines, with a value of $2,357,129. This is far in excess of the figures for last year, which were 902 cars, valued at $2,176,428, and exceeds the number, but not the value, of the 1907 importations—1,008 machines and $3,505,388 value.

Of the machines imported in the month the geographical distribution is as follows:

United Kingdom	7	$18,557
France	136	203,964
Germany	8	21,964
Italy	29	56,477
Other Countries	5	11,207

In addition there were parts brought in amounting to the sum of $50,997. The table of distribution shows that every country except Italy doubled its importation for the month, both in number of machines and value.

The exportations for the same month tell a different story, for the exports of domestic manufacture were nil, while the exports of foreign manufacture show only four machines valued at $12,579, and no parts.



Capt. Thomas S. Baldwin in His Dirigible Airship Making a Successful Flight at North Arlington, New Jersey

PARIS, May 28—The full program has just been issued of the important aeroplane races to take place in the neighborhood of the city of Rheims from August 22 to 29, and which will undoubtedly provide excellent sport of an altogether unusual kind. The ground over which the races are to be held is a vast plain, without trees or any other obstructions, the size of which can be judged from the fact that it has been the scene of some of the largest military reviews Europe has ever known. It is over this course that a special track has been laid down, giving a round of about 6 1-2 miles, over which the aeroplanes will fly without danger of doing injury to spectators if for any reason whatever they are obliged to land during a race. The total prize list amounts to no less than $40,000, which alone is sufficient to assure participation of the world's best aeronauts.

On the opening day, Sunday, August 22, the elimination race for the Gordon Bennett aeronautical cup will be run off, with a view to selecting the three pilots and machines to represent France. The final of the Gordon Bennett event will take place on Saturday, August 28, the winner to receive, in addition to the work of art, a cash prize of $5,000. On the same day the first starters will be sent away for the Grand Prix de la Champage, the prizes for which total $20,000, of which $10,000 goes to the first. The third item on the program for the first day is the speed test for one round of the course, the aviator making the fastest time to be the winner of the $1,400 prize; the second prize is $600. Both the Grand Prix and the circular race will be continued on each day of the meeting, the fastest times on any one day determining the winner. The first series of the dirigible balloon races will also be held on the opening day, the prizes for this amounting to $2,000.

On the second day of the meet the straightaway speed test will be run for the first time, as well as the competition for the passenger carrying aeroplanes, for which the total prizes amount to $2,000. The circular race, comprising one round of the course only, and the dirigible balloon contest will be continued on this day, while Tuesday will be occupied with the same two events.

Wednesday, August 25, will see the second day of the Grand Prix and the fourth day's competition for the dirigible balloons and the circular event. On Thursday, August 26, there will be a modification of the usual proceedings in the shape of a landing competition for spherical balloons, to be followed by the fifth day's races for the circular course and the dirigible balloons. On Friday the last races will be run for the Grand Prix and the sixth attempts made for the circular race and the dirigible balloon contests, these two latter being continued on the Saturday, in addition to the final for the Gordon Bennett cup. The closing day of the meet, Sunday, August 29, will see the final races for the speed test, the circular test, the dirigible balloon test, and a competition for the $2,000 offered to the pilot attaining the greatest altitude.

There are very few restrictions regarding the aeroplanes, any type of machine being admitted and any style of motor being allowed. The regulations, however, forbid the modification or changing of any part after the aeroplanes have been brought to the competition ground. Entries at the rate of $200 per flying machine are received in Paris until the evening of July 22. This sum will be refunded to all pilots crossing the starting line once, and will give the entrants the use of a special shed. Late entries are received until August 10 on payment of double fees, of which amount $20 will be retained by the local committee if the machine crosses the starting line. Garage accommodation is not assured to late entrants.

BALDWIN'S AIRSHIP FLIES REPEATEDLY

NORTH ARLINGTON, N. J., June 1—Captain Thomas S. Baldwin made good all of his promises for the airship which he has constructed in the aeronautical carnival here last week by repeated flights, varying from a few yards to several miles.

The machine is of the dirigible balloon type, the exterior gas bag being about eighty-six feet long. With this small machine Baldwin on Thursday flew nearly two miles at a height of 200 feet. The following day even this performance was bettered when he reached a very high altitude and covered a distance of more than twice the previous flight. The latter achievement was even more meritorious, for the aviator described several circles to prove his perfect control over the machine.

At the luncheon of the West Hudson Aero Club on Monday he was presented with the first commemorative gold medal of the Aero Club of America for these performances.

PLANS FOR THE GERMAN AIRSHIP LINES

WASHINGTON, D. C., June 1—Consul T. J. Albert, of Brunswick, in reporting that the German Aerial Navigation Company, of Frankfort-on-Main, has established the first permanent air-

ship lines in Germany, gives the following very interesting details: It is the purpose of the company at the start to connect fully 30 cities. It has already received patents for its turn halls for motor balloons, and it will erect the first halls in Berlin, Munich and Strassburg, in Alsace. The extensive plans of the company have aroused the liveliest interest on all sides, and their execution appears to be financially assured.

The first line of connection planned is Munich to Dresden by way of Nuremberg, Plauen and Chemnitz. The second line is from Munich to Cassel by way of Ulm, Stuttgart, Mannheim, Mayence, Coblenz, Cologne, Düsseldorf, Elberfeld and Paderborn. The third line is from Berlin to Lübeck by way of Bremen and Hamburg. The fourth line is from Berlin to Königsberg by way of Stettin and Danzig. The fifth line is from Strassburg to Berlin by way of Metz, Trier, Mayence, Frankfurt, Erfurt, Leipzig, Halle and Magdeburg.

WRIGHT PUPIL MAKES NEW FRENCH RECORD

PAU, FRANCE, May 26—Paul Tissandier, Wilbur Wright's first pupil, has established a new French flying record by remaining in the air 1 hour 2 minutes on a French-built Wright machine. The previous French record was held by Henry Farman, who on October 2 remained aloft at Chalons for 44 minutes 32 seconds. The record of Leon Delagrange, with the same type of machine as used by Farman, stands at 30 minutes 27 seconds. Paul Tissandier made his first flight in full charge of the Wright aeroplane on February 18 after seven lessons lasting altogether 2 hours 20 minutes. On this occasion Wilbur Wright was by his side, but did not touch any of the controlling levers. The following day the French pilot made a second flight, lasting twenty minutes, under exactly similar conditions, and was then promoted to the stage of instructor. He is now employed by the French company holding the Wright patents to train pupils in the handling of this machine. Paul Tissandier will be a member of the French team in the Gordon Bennett aeroplane race to be run at Rheims on Saturday, August 28.

BRITISH ARMY AEROPLANE FLIES ONE MILE

LONDON, May 25—It certainly appears that the luckless S. F. Cody has come to the end of his run of failures with the aeroplane which he built last year for the army but which has never yet made a satisfactory flight. On the 14th inst. he made a straightway run of over a mile at a height of 30 feet and repeated the performance a second time. At the third trial, at which the Prince and Princess of Wales were present, the machine struck a bank after covering 200 yards, but without effecting much damage. Hope is now freely expressed that this type of machine will soon begin to display some of the advantages which it is claimed to possess.

ZEPPELIN AIRSHIP FLIES 935 MILES

BERLIN, June 2—After covering a distance of about 935 miles in thirty-seven hours, *Zeppelin II* (the famous airship of Count Zeppelin which replaced *Zeppelin I*, that was destroyed by fire last year), in descending for a fresh supply of gasoline for her engines, near Goppingen, in Wurtemburg, ran into a pear tree with such force as to rip the forward compartment of the aluminum envelope for a space of ninety feet. The accident occurred about 11 o'clock on Monday morning.

The airship left the floating shed at Lake Constance shortly after 9 o'clock Saturday night with Berlin as the objective point, where Emperor William was to witness its arrival. Owing to the strong head winds it was deemed inadvisable to proceed nearer to Berlin than Bitterfield, some four hundred miles from the starting point. The dirigible was here turned about for the homeward course, and the distance covered, while it was in the air, including the maneuvers, prior to the accident, totaled 935 miles. Count Zeppelin, two engineers and a crew of seven men composed the party of aviation.

The trip demonstrates the wonderful possibilities of aerial navigation and the accident in descending could have been avoided by more careful steering. Temporary repairs were made to-day and the airship started on its homeward journey, making about ninety miles the first six hours of its flight.

Doubts Ability to Reach Great Heights—Professor David Todd, of Amherst, is planning a balloon trip in which he will aim to reach the greatest height ever attained by man, more than 20,000 feet. A. Holland Forbes, the aeronaut, however, expresses his doubt as to the ability of any balloon to get that high, stating that the reported altitude of 36,000 feet was accepted without proof. Four miles, he thinks is the limit, and it would be extremely difficult to even get that high. Professor Todd talks of using a steel air-tight basket with arrangements for compressing air in the chamber at high altitudes, and of carrying 10 miles of fine steel wire with which to keep in telegraphic communication with the earth. It has been reported that he has been offered the use of the new balloon of the New England Aero Club, the Massachusetts, and that the ascent will be made from Canton, Ohio.

Wilson Plans Flights at Bangor Fair—Aeroplane flights for the Eastern Maine State Fair at Bangor in the fall are planned by the management and A. V. Wilson, of Bar Harbor. Mr. Wilson has a machine which has been seen in New York and other States, called the Old Hen, and his most successful flight was one of 1,710 feet, at an altitude of 27 feet. It is equipped with an engine of 18 horsepower and will be entered in the competition for the New York *World* $10,000 prize for the fastest time between New York and Albany.

BRITISH CONTESTS PROGRAM FOR SEASON IS LIGHT

LONDON, May 25—This is to be a quiet season as far as races and trials are concerned, for there are to be none of the former and but two of the latter, the smallest schedule the United Kingdom has known since the advent of automobiling.

The Irish A. C. leads off next week with its annual five days' reliability trial, run in two sections, for private owners and the trade respectively.

The more popular Scottish Trial follows in the third week of June and is this year extended to a distance of 1,000 miles. Nearly seventy entries have been booked, the last of all being the new 38 h.p. Minerva, with Knight engine, made by the Belgian licensees. This will be the first appearance of the slide valve engine in open competition, but matters will not rest there, for the Daimler Company are, as usual, concentrating their forces on the hill climbs, of which the Rivington Pike, for the North of England, and Shelsey Walsh, for the Midlands, are the principal events.

There will be no road racing this year, despite the fact that the Isle of Man authorities are willing, and even anxious, that there should be a continuance of the Tourist Trophy series. The gap will be filled to some extent by the Brooklands track, which has four big meets to come off, the first being held next week-end. At this meet interest will be centered on the attempts at record by Baker White's big Fiat, the most powerful car ever turned out by the Turin firm. The rated power of the engine is over the 200-h.p. mark, so that a phenomenal speed is quite a possibility. The other events of the same meeting will be mainly handicap races for amateurs.

Sheep Ranch in Eastern Colorado on the Route of the Tour for the Glidden Trophy

EARLY ENTRIES FOR GLIDDEN TOUR SET NEW FIGURES

PREDICTIONS that the 1909 tour of the A. A. A. for the Glidden, Hower and Detroit trophies would be the largest entered national tour ever held have shown evidences of realization. Paid entries to the number of thirty-three have been received by Chairman Hower, and on May 24 the number was within a couple of being four times as many as were on hand for the corresponding dates of previous years.

Pierce, Premier, and E-M-F lead with four cars each; Chalmers-Detroit, Maxwell, and Moline will be represented by trios; Brush and Stoddard-Dayton will have two apiece, and American Simplex, Hupmobile, Jewel, Glide, Rapid and McIntyre will have single cars. Inasmuch as it is no longer necessary to enter complete teams in order to secure the much-coveted Glidden cup, it is possible for many concerns to list individual cars and parties. The presence of thirty-three automobiles would alone be considered as a tour of good size, but it is stated from the headquarters of the national contest board that this number will be doubled easily, and probably trebled, before the entries close on June 15, or at least before the start, when cars will be received at additional fees.

The mapping out of the route, except a certain section from Minneapolis to Omaha, has been completed, and at present the plans call for a start of the caravan from Detroit on July 12, finishing at Kansas City on July 29, an elapsed time of eighteen days, with fourteen used in running. Dai Lewis and his pathfinding party in the E-M-F touring car traveled a total of 2,832 miles in going over the route, but the figures for those who are to follow were 2,624, showing that the E-M-F had to run over 200 miles more than required. It is likely that the resurvey will lower the official figures by about 100 miles, when some of the directions are changed between the Twin Cities and the Missouri River, taking in Mason City instead of Mankato. Several important reasons for the alteration have arisen, among them being the fact that to go by way of Mankato would necessitate the addition of an extra day to the itinerary. The only way this could be added would be to start on Sunday, or the two days planned to stay in Denver would have to be reduced to one. Both are impracticable, however; the latter because the greatest sightseeing trips of the tour are to be enjoyed there, including excursions to the Garden of the Gods, the Grand Cañon, and other Rocky Mountain points. A fund of $18,000 has been raised by the Denver club for the entertainment of the tourists, and to shorten the stay would be a disappointment both to the hosts and to the guests.

According to the reports of Pathfinder "Dai," the interest in the Middle West over the coming event is intense, surpassing anything that has happened in many years, and throughout the States of Wisconsin, Minnesota, Iowa, Nebraska, Colorado, and Kansas every farmer who talked to the party either owned an automobile or was talking of buying one. Kansas City is the third largest automobile distributing point in the country, and one town passed through between Denver and the finish, Ellis, has a population of 1,500, and there are more than 100 automobiles owned there now. When the Mile-High city was reached the Pathfinders were escorted through the streets by 143 automobiles, bombs were shot off, and a brass band joined in the celebration. The two days scheduled to be spent in Denver are July 24 and 25. Minneapolis will have July 17 and 18, and its autoists are planning entertainment features which will long be remembered.

FLAG TO FLAG CAR PROGRESSES

TORREON, MEXICO, May 27—The Chalmers-Detroit pathfinding car for the Flag to Flag race reached here to-day after making 156 miles in thirteen hours and 310 miles since Monday. To-day will be a day of rest, and will be spent in finding a new guide for the Mexican roads, which are to come on the last leg of the tour to the City of Mexico.

The car is apparently in Chihuahua province and not far from the principal city of the same name, which is but 220 miles from Cuidad Juarez, where the line was crossed. If the general direction thus far be continued, the provinces to be crossed next, with the distances, will be: Durango, 300 miles; Zacatecas, 175 miles; Agua Calientes, 75 miles; Guanajuato, 100 miles, and finally, Mexico province to Mexico City, 175 miles. This makes total from the border line of 1,045 miles, which is by map and air-line distances at that, probably the car will travel 1,500 miles to actually cover this same country. With the distance already traversed, there remain about 1,300 miles before the goal is reached.

INDIANAPOLIS TO CHICAGO AUTOWAY

INDIANAPOLIS, IND., May 31.—A boulevard connecting this city with Chicago is the plan of a number of capitalists of this and other States, according to Charles S. Hernley, of Newcastle, who is interested in the project. Because of the magnitude of the project, which will require a highway 200 miles long, there has been considerable scepticism relative to the scheme, but the promoters assert they are serious in their intentions. The boulevard, by a conservative estimate, is expected to cost from $1,500,000 to $2,000,000.

The plan is to obtain a private right of way between the two cities and build a model highway to be used by automobiles exclusively. The highway will be fenced, and in all probability there will be no speed restrictions.

Mr. Hernly announces that associated with him in the project are Benjamin F. Briscoe, of Tarrytown, N. Y., of the Maxwell-Briscoe Motor Company; Carl G. Fisher, president of the Prest-O-Lite Company and interested in the Indianapolis Motor Speedway, and other automobile men whose names he is not at liberty to mention at the present time.

The company will have an authorized capitalization of $250,000 and shares will be sold at $100 each. As the work progresses the capital stock will be increased.

ROAD TELEPHONE SYSTEM FOR TOURISTS

SANTA BARBARA, CAL., May 31—Telephone communication from almost any point while touring may be a possibility if certain plans outlined in this city are carried out. Fred Spoeri, division contract agent of the Pacific Telephone & Telegraph Company, has suggested a road 'phone for use exclusively by automobilists. By a nominal monthly rental the tourists would be supplied with telephone outfits similar to those used by linemen, and every mile a wire would be run down the pole from the main line, there installing a "jack" or connection. Thus a tourist would never be more than half a mile from a telephone wire, and the scheme would be especially adaptable in southern California, where nearly all highways are paralleled by telephone systems.

CLEVELAND AUTOISTS POSTING SIGNS

CLEVELAND, May 31—Using the old Studebaker "war car," which is also to be employed as a press car in the Glidden tour this year, the officers of the Cleveland Automobile Club are now signboarding a goodly portion of northern Ohio. Old signs are being renewed wherever necessary, while many other highways are receiving signs for the first time. When the work is completed it is expected that the northern part of the State, both east and west of Cleveland, as well as south, will be completely covered with clear road directions.

THE AUTOMOBILE CALENDAR

AMERICAN

Shows, Meetings, Etc.

Nov. 6-13.....Atlanta, Ga., Auditorium-Armory, National Automobile Show.
Dec. 31-Jan. 7....New York City, Grand Central Palace, Decennial International Automobile Show: American Motor Car Manufacturers' Association, with Importers Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
Jan. 8-15.....New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
Feb. 5-12.....Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

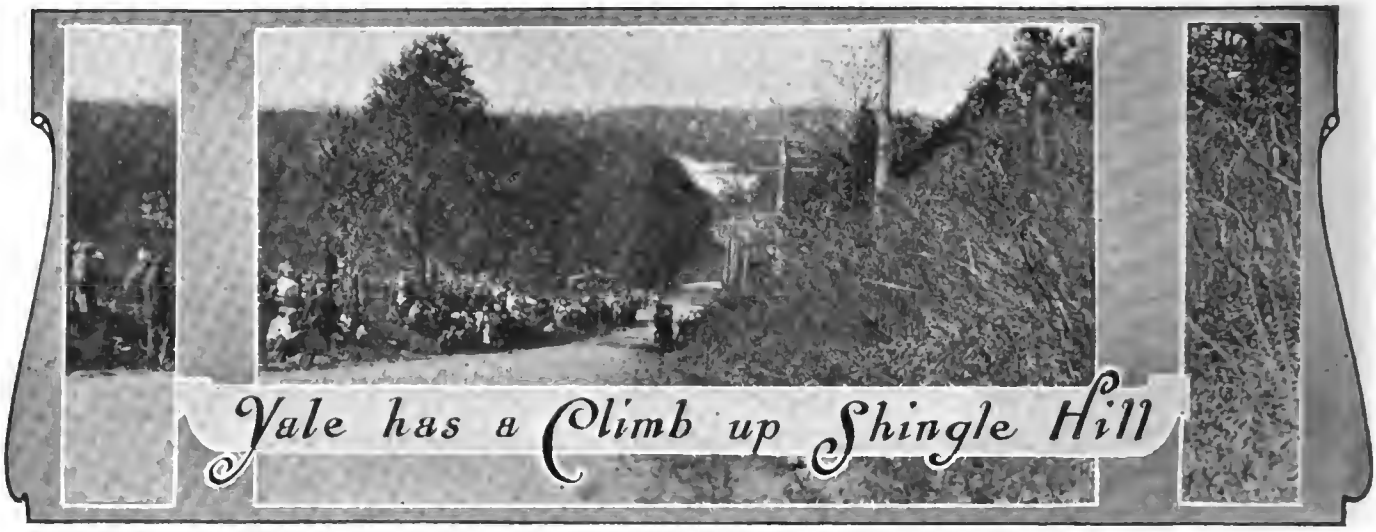
June 5.....Cleveland, O., Hill Climb, Porter Hill, Cleveland Automobile Club.
June 9.....Louisville, Ky., Track Race Meet, Louisville Imperial Council Committee.
June 9.....National Orphans' Day.
June 12.....Wilmington, Del., 106-Mile Sealed Time Run, Delaware Automobile Association.
June 12.....Worcester, Mass. Annual Dead Horse Hill Climb, Worcester Automobile Club.
June 12-14.....New York City, Catskill-Berkshire Endurance Contest, New York Automobile Trade Association.
June 14-18.....Philadelphia Reliability Run to Pittsburg and Return, Quaker City Motor Club.
June 14-21.....Annual 660-Mile Spring Tour Maxwell-Briscoe Motor Club, New York City via Waterbury, Stockbridge, Newburgh, Delaware Water Gap, Philadelphia, Atlantic City, to New York.
June 17.....Readville, Mass., Track Race Meet, Bay State Automobile Association.
June 18-19.....Chicago, Stock Chassis Race for Cobe Trophy and Light Car Race.
June 21-26.....Binghamton, N. Y., Fourth Annual Endurance Run, Binghamton Automobile Club.
June 22-28.....Albany, N. Y., Fifth Annual Tour, Bretton Woods, Portsmouth, Boston, Albany Automobile Club.
June 24-26.....Montreal, Blue Bonnets Track, Race Meet. R. M. Jaffray, Manager.
June 25-26.....Philadelphia, 24-Hour Track Race, Quaker City Motor Club.
July 3 and 5.....Wildwood, N. J., Straightaway Races, Motor Club of Wildwood.
July 4.....Los Angeles, Cal., Southern California Automobile Dealers' Association. Road Races, 250 Miles for Large Cars; 150 Miles for Light Cars.
July 12.....Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.
Aug. 5.....Chicago, Fourth Annual Algonquin Hill Climb, Chicago Motor Club.
Sept. 6-11.....Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
Sept. 15.....Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Oct. 7.....Philadelphia, Second Annual Stock Chassis, 200-mile Race, Fairmount Park, Quaker City, M. C.
Dec. 29-30.....Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

FOREIGN

Races, Hill Climbs, Etc.

June 10-18.....Germany, Prince Henry Cup Competition.
June 14-19.....Scotland, Annual Scottish Reliability Trials.
June 20.....France, Bologne-sur-Mer Course, Volturette Race, Auspices "L'Auto."
July 13-17.....Belgium, Ostend Automobile Race Week.
Aug. 22-29.....France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Sept. 5.....France, Mont Venteoux Hill Climb.
Sept. 19.....Austria Semmering Hill Climb.

Emperor William of Germany has signed the muchly contested motor liability law which now becomes a stern reality. It remains to be seen what influence it will have on the trade.



Yale has a Climb up Shingle Hill

NEW HAVEN, CONN., May 31—Some tall hill-climbing took place up Shingle Hill on the afternoon of May 26, for an overflowing entry was attracted to the second ascent of the Yale Automobile Club. While the "big fellows" attracted the interest of those seeking the spectacular, the performances of the stock cars found the greatest favor, for those contests involved machines, duplicates of which are purchaseable by the general public. The Simplex got the high-price class with Stoddard-Dayton the star in the next brigade and then Knox took the prize in two divisions.

A feature was the perfect regulation of the course, not by uniformed officials, but handled in a masterful manner by the students themselves. The fact that the 15,000 spectators did not crowd upon the road or embarrass the contestants is proof sufficient of the result. Shingle Hill is not in itself a great incline, and, in fact, when some of those visitors who have witnessed the climbs at Wilkes-Barre, Mount Washington and elsewhere arrived they asked the whereabouts of the "hill," not realizing that they were upon it. The distance covered was seven-eighths of a mile, with two main rises, one of about 15 per cent close to the start and the other near the finish.

It was expected that David Bruce Brown would capture the free-for-all honors with the 120-horsepower Benz, and he did so handily, flashing up the hill in 51 1-5 seconds.

The motorcycles had several sections to themselves, depending upon their piston displacement for classification, and many operated by Yale students, among whom this type of locomotion is very popular. Bill Wray, not of Yale, was the star, and his twin-cylinder Indian flew over the course in 52 2-5 seconds.

Under the direction of prominent officials the events were dispatched in quick time and to the gratification of all concerned. Fred J. Wagner was the starter, and Robert Lee Morrell acted as referee. Summaries of the auto events follow:

STOCK CARS SELLING FOR $4,001 OR OVER.

No.	Car.	H.P.	Driver.	Time.
1.	Simplex	90	Moult	1:04
2.	Simplex	60	Broesel	1:05 3-5
3.	Isotta	30	Pepperday	1:07 2-5
4.	Lozier	45	Beebe	1:13 3-5
5.	Stearns	30	Doyg	1:16 1-5

STOCK CARS SELLING FROM $3,001 TO $4,000.

1.	Stoddard-Dayton	60	Miller	1:05 3-5
2.	A.-K.	48	Reppingill	1:19 3-5
3.	Packard	30	Bourne	1:21 3-5
4.	Thomas	70	Bran	1:23 3-5

STOCK CARS COSTING UNDER $3,000.

1.	Knox	38	Bourque	1:00
2.	Chalmers	40	Cameron	1:02 1-5
3.	Chalmers	40	Lorimer	1:05 3-5
4.	Buick	30	Burman	1:06 4-5
5.	Stoddard-Dayton	45	Tuttle	1:07 1-5

CARS SELLING FROM $2,001 TO $3,000.

1.	Knox	38	Belcher	1:05 1-5
2.	Chalmers	40	Cameron	1:07 3-5
3.	Stoddard-Dayton	45	Tuttle	1:08 2-5
4.	Chalmers	40	Lorimer	1:09 4-5
5.	Knox	38	Bourque	1:10

CARS SELLING FROM $1,251 TO $2,000.

1.	Buick	18	Burman	1:07 3-5
2.	Buick	30	Bull	1:18 1-5
3.	Chalmers	30	Decker	1:35 4-5

CARS SELLING UNDER $1,250.

1.	Buick	18	Burman	1:19 4-5
2.	Overland	22	Gates	1:56

FREE FOR ALL—ALL MAKES AND POWERS.

1.	Benz	120	Brown	:51 1-5
2.	Panhard	120	Webb	:57

4.	Knox	38	Bourque	1:00 2-5
5.	Columbia	32	Coffee	1:00 4-5

Bourque in Knox Winning His Stock Car Class

Moult Driving Simplex to Victory at New Haven

Driver David Bruce Brown, His Benz and Mechanician

Where the Officials Figured Out the Results

PEERLESS AND MERCER WIN AT TRENTON

TRENTON, N. J., May 31—Peerless and Mercer automobiles to-day won in their respective classes in the run-off of the tie made in the Delaware Valley endurance contest on May 17. Over a circuit of 64 miles, it required six laps to produce a winner, and the Mercer took an extra round for good luck. Out of the 21 starters in the original contest there were 12 with clean records, but only eight appeared for the supplementary event this morning. They were: Peerless, Oldsmobile and Stoddard-Dayton, in the class for cars costing more than $2,000; and Mercer, Overland, Regal, Maxwell and Crawford, in the class for cars selling for less than $2,000. The Stoddard-Dayton made one round and was then withdrawn, for its owner did not wish to punish his own car unnecessarily; and the Oldsmobile completed the 384 miles perfectly, but inasmuch as both the Olds and the Peerless were entered by R. C. Manning, he directed that the Olds should take second place, giving the Peerless first.

The Crawford car ran smoothly until dark to-night, when it had trouble with its lights and driver Shedd then withdrew. The Maxwell withdrew in the first round, and on the second the Regal skidded into a ditch at Cooketown. It was not damaged, but did not continue in the contest. The Overland was penalized for lateness on the sixth lap because of darkness and the absence of headlights. Its driver has protested the Mercer because the driver of the Trenton-made car was handed a searchlight at Cooketown, thereby enabling him to drive faster in the dark. The Mercer Company suggests a duel contest on the fair grounds track, if the protest is upheld, to run the two cars until one stops, with a maximum allowed speed of 40 miles per hour.

WORCESTER'S DEAD HORSE CLIMB MUCH ALIVE

WORCESTER, May 31—Indications point to the most successful high climb in the history of the Worcester Automobile Club, scheduled for Saturday, June 12. The entries are coming in rapidly and are very representative. Permits for the use of the hill have been granted by the Worcester Board of Aldermen and the selectmen of the town of Leicester, the hill being in the two towns. The arrangements for the hill climb have been left with President John P. Coghlin, of the Worcester Automobile Club, and he will select his committees later, they being taken from the various clubs in Massachusetts. Under the rules of the Contest Board of the American Automobile Association, a representative of the board must be present at the climb, and it is probable that Harry W. Knights, of Boston, representative on the board from Massachusetts, will act at the climb.

DIAMOND COMPANY OFFERS CASH PRIZES

AKRON, O., May 31—Cash prizes for the drivers in the Western stock chassis races, the Cobe and light car trophy events, have been offered by the Diamond Rubber Company of this city. The aggregate is $2,775, divided as follows: Driver with Diamond equipment who wins first place, $1,000; second, $750; third, $500. For the Indian trophy, light car race: Winner on Diamond equipment, $300; second, $150; third, $75. The Diamond tire camp will be established upon the course a week in advance of the dates of the races, June 18 and 19, and will be in charge of J. D. Tew.

Line-Up for the Start of the New Jersey Automobile and Motor Club's Endurance Run in Front of Club House

NEW JERSEY'S BIG CLUB GIVES A RUN FOR AMATEURS

NEWARK, N. J., May 31—Weather conditions did not favor the endurance run of the New Jersey Automobile and Motor Club for its non-trade members. Originally scheduled for May 22, it was postponed, because of hard rains, to May 27 and held them in a driving rainstorm. In spite of these handicaps, however, the event was another success in the list of those held by the club, for there were twenty-one starters, of which fifteen finished and thirteen had perfect scores. Three classes divided the contestants, according to horsepower, 20 or less, 20 to 30, and over 30 being the important figures in the case; and in these definite winners were secured in the first two and a three-cornered tie in the last. The rules called for a run of 193 miles in two laps, with the circuit between Newark and Hackettstown. The schedule required an average speed of 19.3 miles an hour, and the cars had to check in at the Newark control within three minutes of their appointed times on each trip. In addition to this it was necessary to keep the wheels moving at all times from Dover to the finish, a distance of 28.1 miles.

In each class it was announced that the car which came nearest to crossing the line exactly upon the second—for seconds were watched carefully—would be declared the winner. There were four trophies: Class A, silver trophy, donated by W. S. Thomas; Class B, silver cup, donated by W. C. Crosby; Class C, silver cup, donated by the Sunday *Call;* silver trophy for the best Maxwell performer, donated by the Maxwell-Briscoe Motor Company. In addition to these, the club will present to each perfect score driver a loving cup.

H. A. Bonnell captured premier honors by carrying off three of the trophies with his Maxwell tourer, winning Class B and the Crosby cup by having the best score of the three Maxwell entries, securing the Maxwell challenge trophy, and by having a perfect score getting the regular club prize. A two-cylinder Reo, the only car in the contest not of the four-cylinder type, driven by D. J. Holmes, won class A, although penalized 17 points, three of which were for three minutes carbureter attention on the road, and the other 14 for adjusting a spark plug at a two-point-a-minute penalty. This car and the second in the same class were the only ones to receive demerit marks. The second was a Buick driven by W. F. Hopping, and lost 18 minutes or 36 points on the second lap. Mr. Bonnell was the only one in class B who crossed the tape both times on the second, but such was not the case in class C, where three accomplished the difficult act. These were F. A. Croselmire in a 40-horsepower Locomobile, F. L. Kramer in a 35-horsepower Jackson and W. C. Crosby in a 50-horsepower Marmon. Of the others who completed the circuits within the three-minute allowance, there was in each case a slight earliness or lateness, sometimes not more than a few seconds.

Checking out at 8 o'clock the contestants ran through Springfield, Morristown, Madison, German Valley, over Schooley's Mountain to Hackettstown. Returning the route led through Allamuchy, Dover, Caldwell, Montclair and Bloomfield. The roads were excellent with the exception of a few miles between Hackettstown and Dover, and even there they were not bad, simply muddy and rough. The rain soon made the roads slippery, however, and this was responsible for an accident to a Mitchell roadster driven by D. J. Scott, in which the observer, E. R. Carter, of Tompkinsville, S. I., had his collar bone broken. The car was descending a hill at Allamuchy and skidded over to the right of the road, its right rear wheel hub hit a protruding rock and the impact threw the car over toward the other side. Scott could not regain control in time to keep from hitting a telegraph pole, cutting it in half and throwing out all the occupants. Carter was the only one hurt and a physician was summoned to attend to him. He returned to the city by train. There were but two other exciting incidents, both at the starting line, and only the presence of a fire wagon belonging to the Tea Tray Company prevented a conflagration. In filling up for the second round some gasoline was spilled around Ward's DeDietrich and it caught fire. The flames damaged the rear of Kramer's Jackson and the DeDietrich slightly, but the fire extinguishers made short work of the trouble and both cars went on their way. After checking in at the completion of the run, C. E. Callard's Marmon skidded into two Maxwells, one

an official car belonging to J. W. Mason and the other Mr. Bonnell's winner, damaging the fenders on both, and shearing the left rear spring from the frame gooseneck of the latter. On the first round the Craig-Toledo, driven by R. G. P. Dieffenbach, threw both rear tires in skidding and had to withdraw. There was a great deal of tire trouble, the Chalmers-Detroit belonging to W. L. Ferguson having five punctures, and he withdrew after finishing one lap.

The officials were: Referee, Paul E. Heller; starter, Mayor Jacob Haussling; committee, J. H. Wood, chairman; F. C. J. Wiss, H. D. Bowman, D. C. Reynolds, A. B. LeMassena, J. L. Adams, Jr.; C. A. Westervelt. The official cars were: Pathfinder, Cadillac, C. E. Fisher; press, Marmon, Rickey Machine Company; committee, two Maxwells, J. W. Mason. The observers were students from the Stevens Polytechnic Institute. The summary follows:

CLASS A CARS, TO AND INCLUDING 20-H.P.

No.	Car.	H.P.	Driver.	Score.
25.	Reo	20	D. J. Holmes	17
11.	Buick	18	W. F. Hopping	36
7.	Buick	18	J. J. C. Humbert	Withdrawn
19.	Mitchell	20	D. J. Scott	Withdrawn

CLASS B CARS, 21-H.P. TO AND INCLUDING 30-H.P.

No.	Car.	H.P.	Driver.	Score.
1.	Maxwell	28	H. A. Bonnell	Winner
6.	Maxwell	28	M. R. Sherrerd	Perfect
16.	Maxwell	28	Andrew Heuschkel	Perfect
17.	Autocar	30	M. A. Carpenter	Perfect
24.	Crawford	25	F. G. Goeken	Perfect
14.	Cadillac	30	A. B. Ward	Withdrawn

CLASS C CARS, 31-H.P. AND OVER.

No.	Car.	H.P.	Driver.	Score.
2.	Locomobile	40	F. A. Croselmire	Tied
9.	Jackson	35	F. L. Kramer	Tied
10.	Marmon	50	W. C. Crosby	Tied
3.	Oldsmobile	35	W. H. Cornwell	Perfect
4.	Marmon	50	C. E. Callard	Perfect
8.	DeDietrich	20	R. S. Ward	Perfect
12.	Haynes	50	W. E. Shuttleworth	Perfect
20.	Flat	35	A. N. Elsele	Perfect
5.	Craig-Toledo	40	R. G. P. Dieffenbach	Withdrawn
18.	Chalmers-Detroit	30	W. L. Ferguson	Withdrawn
26.	Flat	35	W. B. Gibson	Withdrawn

BRIGHT PROSPECTS FOR BINGHAMTON RUN

BINGHAMTON, N. Y., May 31—With three weeks still to pass before the start, there are already 21 entries for the fourth annual tour of the Binghamton Automobile Club. It is expected that there will be at least 30 cars, and likely more, to leave this city on the morning of June 21, to be gone until the evening of June 26. The tour will be essentially a pleasure one, for there will be a large number of private owners in the party, but there is enough of the competitive nature about the event to make it worth while to win. The outlook is brighter than ever before, and a number of persons have joined the club simply to be able to take a run which they have always desired to make. The rules are such that the trip will be a sight-seeing one, with a schedule so low and roads so good that easy runs may be made and short stops at particularly interesting points. A noon control will be established each day for lunch and night stops made at Albany, Boston, Hartford, Conn., and Newburgh, N. Y. One entire day will be spent in seeing Boston. The distance to be covered is 761 miles, of which more than 490 is macadam and the remainder good dirt. A pathfinding car will start over the route within a few days, making up the directions and also paying attention to features of the country through which the autoists will pass.

ALBANY HILL CLIMB ABANDONED

ALBANY, N. Y., May 31—It has been decided by the Albany Automobile Club that the climb which it proposed to hold on the Kenwood Hill on June 5 will be abandoned for the present season. According to Secretary Martin lack of entries is the cause, for it had been stipulated that there should be at least three entries to fill each of the 17 events and sufficient had not been received to warrant a carrying out of the affair.

Secretary Bonnell and Triple Prize Winning Maxwell

SEALED BONNET CUPS AWARDED AT BALTIMORE

BALTIMORE, May 31—Six cups will be awarded by the Automobile Club of Maryland to the cars that made the best records in the sealed bonnet contest and endurance run under the club's auspices on Saturday, May 15. This decision was reached at a meeting, Friday, of the Contest Committee of the club. The Winton 48-horsepower and Packard 30-horsepower were tied in Class A, each with two points penalty, so that each will receive a cup. Two cups will also be awarded in Class B, the successful cars being the 35-40 horsepower Gaeth and the 45-horsepower Stoddard-Dayton, each with twelve bad marks against them. The 40-horsepower Studebaker finished in this class with a perfect score, but was ineligible for a prize, as it was a racer and non-contestant.

The decision to give the Gaeth car a cup was made after the penalty had been reduced from 45 points to 12 points. The original heavy penalty was given on technical examination because it was claimed that the car's gasoline tank leaked and that it had a broken muffler pipe. Upon closer examination it was discovered that the car's gasoline tank did not leak, but that this apparent condition was in reality due to the slopover from the fill. Secretary Darling, of the Auto Club and a member of the Contest Committee, said that part of the points were also reduced on the Gaeth car because of a lower value to replacement of parts of the muffler pipe.

The 28-horsepower Franklin, with a perfect score, will get the cup in Class C, and the 16-horsepower Hupmobile will be the trophy bearer in Class D.

The arrangement to give separate cups will obviate the necessity of having a run-off. It is likely that the tied contestants will have a chance to get together in the next contest.

Champion Cyclist Kramer Was a Perfect Score Jacksonite

PREPARATION OF A CAR FOR SPRING USE

In the yearly overhauling of a car, preparatory to its use for the ensuing season, there is too much of a tendency to trust implicitly those who have the work in hand. It is a usual fact that the ordinary owner when he has hired a garage to go over his car does not upon its receipt in supposedly perfect shape examine it thoroughly to see how many nuts were left off, how many cotter pins were omitted, and how many other little parts were not put together absolutely right. Then, too, many who would check up the corner garage in this fashion would not think of overseeing the same work when done by the manufacturer of the car. The reasoning which prompts this is doubtless that the latter has superior facilities for doing the work and a superior set of men to do the putting together.

The latter is fortuitous, for the men employed in the factory are only human, the same as those in the corner garage. For this reason, if for no other, the car just returned from the factory should be carefully and painstakingly gone over from one end to the other, in order to check up all of the little details, none of which would be too small for the owner, but some of which might have been too microscopic for the mechanic on the job.

It is a matter of record that a number of accidents happen each Spring from this cause, and for which there is not a particle of excuse. One case recently heard of was that of a man who had sent his car to the factory and paid a large sum to have the whole chassis revised and all defects corrected. The car was returned to him as all right, and he immediately took his family out for a ride. After a few hours' riding he was stopped when going at a rather high speed by a man who called his attention to one of the front wheels. Upon close examination this was found to be very loose, so much so that another half mile would have seen it part company with the axle. At the speed the car was traveling this would have been fatal to the occupants. The reason for the wheel being loose was the omission of a cotter pin, in conjunction with which a loose nut was a criminal offense. As it turned out no one was hurt, and the only result was that from now on at least one car owner will look over and check his entire car, whether the garage or the manufacturer does the work of putting it in shape.

* * *

ECONOMY RATHER THAN SPEED ALONE

As the automobile increased in power and reliability, its tasks were multiplied for the various tests in which it was asked to participate. Track racing has become almost obsolete for the reason that in this form of competition the driving of high-powered cars transgressed beyond the limits of sanity. While an occasional meet of this character is held, the number now is meager and hardly worth any serious attention.

It begins to look as though a similar state of affairs is shortly to be reached in the matter of speed hill climbs. Usually, ascents are selected, including dangerous stretches, the successful covering of which requires the exercise of the greatest skill on the part of the driver. In many instances, a victory comes only to the driver who exhibits the greatest amount of foolhardiness and luckily escapes without danger to car or harm to self.

Scarcely a roads grade now exists, no matter how precipitous, throughout the country which cannot be climbed by a good car properly geared and driven by a capable operator. Indications are more than marked that the hill climb is an event that will follow in the trail of the discarded track meet, for future competition is certain to trend toward economical operation rather than demonstrating ability to cover a given course in the shortest space of time.

* * *

THE VETO OF AN AUTOMOBILE BILL

Unquestionably surprised were many New York State automobilists over the veto of the proposed automobile law by Governor Hughes, who decided at the eleventh hour that the proposed Allds-Hamm measure was not justified even by the necessity of urgent funds for the upkeep of State roads. There is much well worth the reading in the veto of this unusual governor, who perhaps is more of a politician than is generally surmised, for it looks to those who were aware of the progress of events as if this chief executive had even revised his own opinions when he dashed to the ground the hopes of those who expected that he would approve of the new law.

The Governor is both right and wrong in the reasons for his veto, and the automobilist, though he dissents in not a few particulars, will find profitable reading in studying the veto.

HUGHES VETOES PROPOSED NEW YORK LAW

ALBANY, N. Y., May 31—The automobilists of New York State are still pondering over the veto of the Allds-Hamm automobile bill which Governor Hughes last week announced. In a memorandum of considerable length the Governor explained why he had decided to veto the proposed law, stating that even the need of money for the upkeep of State roads did not justify him in approving of a measure which he considered contained enough defects to cause him to withhold his signature.

The New York State Automobile Association and the Automobile Club of America used their best endeavors in securing the passage of the bill in the two branches of the Legislature, and naturally the representatives of these two bodies are inclined to express much astonishment at the unexpected veto, especially in view of the fact that the Governor concerned himself in aiding the passage of the measure by emergency messages when its death seemed imminent through a difference of opinion as to whether the Secretary of States office or the State Highway Commission should handle the registration money.

"The Governor is wrong when he says in his brief that the bill deprives the police authorities of the power to regulate traffic," said Charles Thaddeus Terry, counsel to the American Automobile Association. "It does just the reverse. By removing the restriction as to the limit of miles per hour, it places in the hands of the police the power to determine whether or not an automobile is being driven in a careless or negligent manner, no matter how fast it is going. It may be going six miles an hour on Broadway and the speed be reckless. It all depends on the surroundings.

"I think the Governor laid too much stress on the opinion of Mayor McClellan that the traffic regulations of the city would be interfered with. The Mayor's fears were groundless. They were gathered from a superficial examination of the provisions of the bill by the city authorities. Caution will become the universal test of speed. It is the law now in Connecticut, Massachusetts, Vermont and Pennsylvania, and will be so in every State."

"The veto is unfortunate," said W. W. Niles, counsel to the Automobile Association of America. "The bill, if it became a law, would have resulted in more stringent traffic regulations so far as automobiles are concerned. It would have given the police greater supervision.. I think the Governor's view is wrong."

Herewith will be found the full text of the Governor's announcement of his disapproval of the measure:

STATE OF NEW YORK,
EXECUTIVE CHAMBER,

Albany, May 26, 1909.

Memorandum filed with Assembly Bill No. 2,413, entitled "An act to amend the highway law, by repealing Article 11 thereof and inserting a new Article 11, in relation to motor vehicles.

NOT APPROVED.

The study of this measure has convinced me that it would be unwise to enact it into law. It is true that it provides for an increase of the State's revenues, and in view of the amounts we are expending in the improvement of our highways and of the difficulties of maintenance under new uses, the revenue provisions of the bill are important.

But the subject of paramount consideration at this time is protection to life and limb. We are passing through a period of adjustment when the natural hostility of many to new highway conditions is increased by abuse of privilege, and others are chafing under what they regard as vexatious restraints and unjust exactions. Nothing can be more certain than that the use of motor vehicles will largely increase, that the number of accidents will diminish, and that usage and common sense will largely do away with present evils. During this transition period, however, there should be the utmost care in legislation so that matters should not be made worse instead of better. There are many good provisions in this bill, and it has been strongly urged that it should have a trial. But it seems to me better to wait and to secure an improved bill, than to enact a measure as defective as this one appears to be.

The present law provides specific speed limitations of 10 miles an hour where the territory is closely built up, 15 miles an hour elsewhere in a city or village, and 20 miles an hour elsewhere outside of a city or village. In addition, the present law also provides for a reasonable rate of speed in all cases—that is, that no one shall operate a motor vehicle on a public highway "at a rate of speed greater than is reasonable and proper, having regard to the traffic and use of the highway, or so as to endanger the life or limb of any person, or the safety of any property."

This bill abolishes the specific speed limitations, and with certain changes in phraseology with regard to the duty of care, proposes as the sole requirement as to speed, the following:

"Sec. 287. Speed permitted.—Every person operating a motor vehicle on the public highways of this State shall drive the same in a careful and prudent manner and at a rate of speed so as not to endanger the property of another or the life or limb of any person; provided that a rate of speed in excess of 30 miles an hour shall be presumptive evidence of reckless driving."

There is much force in the suggestion that requirements of due care cannot be accurately reflected in arbitrary speed limits. But it must also be remembered that in this field as in others a large number of injuries must inevitably be due to mere accident where negligence cannot be satisfactorily proved. It is public policy in dealing with these matters not simply to see that negligent persons are held to account, but also by reasonable regulation, to diminish the risks of preventable injury. This is sought to be accomplished by speed restrictions. And it is still an open question whether at this stage in our progress toward the wider use of these vehicles of pleasure and convenience, it is safe to rely simply upon a requirement of care and prudence with all the difficulties that attend actual proof of want of care.

It is certain, however, that whatever may be said as to the wisdom of such a rule with regard to the open country, or in sparsely settled towns, we should not deprive our large cities of the right to make reasonable traffic regulations to insure the safety and convenience of the public.

About one-half of the population of this State is within the City of New York, and the Mayor of that city has sent me a vigorous protest against the provisions of this bill. And whatever else may be said of it, it should not become a law if it takes away from the authorities of New York City that reasonable traffic control without which conditions in the metropolis would be intolerable.

The present motor vehicle law took effect on May 3, 1904. It is true that it prohibited, with certain exceptions, the making of local ordinances. But the next year, 1905, the Legislature amended the Greatsr New York charter so as to give the police department the right to "regulate, direct, control, restrict and direct the movement of all teams, horses, carts, wagons, automobiles and all other vehicles in streets, bridges, squares, parks and public places for the facilitation of traffic and the convenience of the public as well as the proper protection of human life and health," and to that end authorized the Police Commissioner to make "such rules and regulations for the conduct of vehicular traffic in the use of the public streets, squares and avenues as he may deem necessary." Any prior provisions of law inconsistent with this authority were repealed.

The present bill takes away from the local authorities the power "to pass, enforce or maintain any ordinance, rule or regulation * * * excluding any such owner or chauffeur from the free use of such public highways or in any other way respecting motor vehicles or their speed upon or use of the public highways." It expressly provides that any ordinance, rule or regulation "now in force or hereafter enacted" which is "in any wise inconsistent" with the provisions of the act shall have no effect. The only exceptions are the powers (1) to regulate vehicles offered to the public for hire, (2) to regulate processions, assemblages or parades in the streets or public places, (3) to set aside a specified public highway for speed contests or races, and (4) to exclude motor vehicles from cemeteries.

In short, it would practically abolish municipal traffic regulations as to private motor cars. Any one acquainted with conditions in New York City knows how much of the public convenience and safety is due to the maintenance of proper traffic regulations and must recognize the impropriety of making such regulations impossible in the interest of the free passage of motor cars.

It would also appear that under this bill there would be no power vested in the local authorities to exclude motor trucks or motor vehicles used for commercial purposes from the parks of the city, which are included in the "public highways" as defined in

the bill. It would deprive the local authorities of any power they now possess for this purpose.

These defects are grave enough to compel the disapproval of this bill.

But, it may be added, with regard to the general application of the bill, that the abolition of specific speed limitations and the substitution merely of the rule of due care should carry with it stringent penalties in case of negligent driving. It would seem that the penalties for actually proved negligence should be heavier than those imposed for merely exceeding an arbitrary speed limit.

The penalties provided for in this bill, with respect to violations of speed requirements, are less stringent than those of the present law.

A comparison shows the following results:

For a first offense: Under the present law, a fine not exceeding $100; under the proposed law, a fine not exceeding $50.

For a second offense: Under the present law, a fine not less than $50 nor more than $100, or imprisonment not exceeding 30 days, or both; under the proposed law, a fine not exceeding $50, or imprisonment for not exceeding 30 days, or both.

For a third or subsequent offense: Under the present law, a fine of not less than $100 nor more than $250, and imprisonment not exceeding 30 days; under the proposed law, a fine of not exceeding $50 and imprisonment not exceeding 30 days.

It is true that the provisions of the proposed law for maintaining records and distributing information of prior convictions are very useful. But these advantages are more than offset by the inadequacy of other provisions.

The deterrent feature, which is relied upon to secure obedience to the law, is the requirement of an actual imprisonment upon conviction for a third offense. And the importance of maintaining records of prior convictions is to pave the way for this punishment of the confirmed violator of the law. But the present bill limits the amount of bail which may be taken to $100. It provides that where the magistrate is without jurisdiction to try the offense, and the defendant "charged with the violation of any provision" of the act is held to answer, the magistrate must admit the defendant to bail upon his giving a surety company bond, or an undertaking, in the sum of $100, or upon his deposit of a like amount in cash. If records were maintained so that imprisonment were the inevitable consequence of conviction for a third or subsequent offense, such bail in many cases might be wholly inadequate.

It is apparent that careful drivers of motor cars, who have no desire to violate the law, are now held within what they believe to be unjust restrictions and are frequently made the victims of an abuse of legal process. But the remedy for any existing injustice must carry with it appropriate safeguards, and the more that is left to the judgment of the driver, the more important it is that recklessness should be heavily penalized.

The bill contains restrictions upon the use of cars without the consent of their owners, a frequent source of accident. But such a restriction is also contained in a separate bill amending the penal law, and will not be lost by the disapproval of this bill. It would also seem advisable that better means should be provided, with respect to the issuing of licenses, for ensuring the competency of chauffeurs. One of the imperfections of this bill is that the useful provision for the suspension of licenses does not apply to violation of the requirements as to safe speed.

In view of these considerations, other objections to the bill need not be discussed. The bill is disapproved.

(Signed) CHARLES E. HUGHES.

PENNSYLVANIA NEW LAW IN EFFECT EXCEPT LICENSING!

PHILADELPHIA, May 31—That section of the recently enacted Townsend automobile law which continues the method of licensing resident automobilists prescribed by the 1905 act until December 31 next, when it will be superseded by that prescribed in the new law, has bothered all concerned not a little. A careful reading of the new law will show that Section 25 applies only to licensing, and was inserted to save automobilists from the necessity of "coming up double." The remainder of the law went into effect as soon as the Governor attached his signature to the bill.

Even the police officials seemed to be a little hazy in the matter, and a few days ago Wesley Burdett and E. A. Strong, local automobilists, were held by Magistrate Scott until he could look into the law. They had been apprehended by Motorcycle Policeman Morley, in Chestnut Hill, a suburban section. The "cop" swore they were going at twenty-three miles an hour.

Attorney G. Douglass Bartlett, the Quaker City Motor Club's legal sharp, was put on the job, and when the case came up he asked for the immediate discharge of his clients on the ground that they had broken no law. Bartlett quoted the new law and showed where the policeman had been working under the 1905 law, which had been superseded by that of 1909. After examining the law the magistrate agreed with Mr. Bartlett and discharged the prisoners. The local "cops" are now hard at work amending their painfully acquired arithmetic to meet the demands of the new law.

MORA TALKS FOR FEDERAL LAW

"Automobile regulations may come and go," says S. H. Mora, treasurer of the American Motor Car Manufacturers' Association, "but as the touring season is renewed each year the fact is strongly thrust upon us that no automobile law will ever be satisfactory and just until a national Federal bill is enacted, making one registration number good in all States.

"It is unquestionably unfair that automobilists in the use of the interstate highways should be obliged to submit to the diverse State regulations as to registration and identification when such State requirements result in the imposition of as many different taxes as there are States to pass through.

"Under the present automobile regulations there is a necessity sometimes of procuring new numbers for the car and in some cases adding these numbers to those already in place; in other cases removing all those except the registration number of the particular State through which the tourist is passing at the time; in some States carrying one number, in others two numbers; in some States painting the number on the machine, and in others attaching it to front or rear, or both.

"There is not any question but there should be some system of identification which shall be uniform and at the same time effective. The varying requirements which are now enforced in the various States throughout the country defeat the very object of the State statutes, inasmuch as they result in increased confusion instead of clear identification."

AUTOISTS' METHOD OF WINNING JUDGES

CLEVELAND, May 31—There is a good story on a prominent Cleveland judge going the rounds in this city and its lesson may aid other clubs in winning over members of the judiciary to the side of the automobilists. This judge was recently caught by one of the automobile club members, speeding down Euclid Avenue and was duly reported at the club office. A courteous letter was sent him, stating that he was "violating the laws of Ohio" and requesting that he curb his desire for speeding. Within twenty minutes after the receipt of the communication the bench member appeared at the club rooms with profuse apologies to Secretary Forbes, thanked him for calling his attention to the matter, joined the club and carried away ten application blanks for his friends. "Pinching" judges in this manner is an effective way of bringing to their attention the fact that automobile clubs are doing much to gain respect for the laws.

IS THIS MICHIGAN ORDINANCE A JOKE?

MARSHALL, MICH., May 31—This town of 4,361 inhabitants will probably have an automobile ordinance that will make its watchful residents wealthy at the expense of automobilists. The "city" attorney is compounding a statute which will provide a fine of $100 for automobile drivers who send their cars over the streets at a rate of more than eight miles an hour, and the informer will receive one-half of the money.

What the Clubs Are Doing These Days

QUAKER CITY'S ARE ON THE INCREASE

PHILADELPHIA, May 24—Twenty-two new members were added to the club's total at last week's meeting of the board of governors of the Quaker City Motor Club, and the officials are now realizing that before many months a waiting list will have to be started. The 200-mile stock chassis race in Fairmount Park next October came up for discussion, and it was decided to limit entries to American-built cars only. The resignation of Max R. Green from the board having left a vacancy, Joseph Keir was appointed in his place, he having polled the greatest number of votes of the candidates who failed of election at the annual meeting. Chairman Bartlett, of the law and ordinance committee, reported that the codification of the new Pennsylvania and New Jersey automobile laws was in the hands of the printer and would be ready for distribution to the members in a few days.

The report of the club's official scout, "Doc" Overpeck, was also read, and the itinerary of the five-day endurance run to Pittsburg and return, June 14-18 next, as decided upon by the pathfinding party, indorsed and ordered to be made public. It shows a total mileage of 750.5 miles for the round trip—412.2 going and 338.3 returning—with overnight stops at Williamsport, Johnstown, Pittsburg, and Lewistown. Quite a number of entries have already been received for the four classes—A, touring cars listed at over $2,000; B, touring cars, $2,000 or less; C, runabouts, over $2,000; D, runabouts, $2,000 or less.

The club is preparing, as usual, to be well represented at the Wilkes-Barre climb on May 31, fully a score of members having signified their intention of making a three-day trip of it, starting Saturday noon, and reaching home at the same hour Tuesday.

SPRINGFIELD (O.) CLUB ELECTS OFFICERS

SPRINGFIELD, O., May 24—Co-operation with the State automobile department and the good roads work were subjects of interest at the annual meeting of the Springfield Automobile Club held on Thursday evening. The election of officers resulted as follows: President, Frank R. Packham; vice-president, P. E. Montanus; secretary and treasurer, George E. Mentel. These with Benjamin P. Johnson and George R. Prout constitute the board of governors. M. M. Maxwell, secretary of the good roads commission, outlined the work to be attempted by his board with the aid of the automobile clubs and various other associations. The State automobile department was represented by its superintendent, Fred H. Caley, who gave a talk on the work of the department.

COLUMBUS WILL ENTERTAIN ORPHANS

COLUMBUS, O., May 29—The first week in June, set by the A. A. A. for National Orphan's Day, was not convenient to the Columbus Automobile Club, so the date was fixed at June 19. On this day it is expected that 1,800 children rounded up by the Salvation Army and the Volunteers of America will take advantage of the club's hospitality, this number being in excess of last year by 200. More than 200 autoists have pledged themselves or their cars so that success is assured. The start will be made from Broad and High streets early in the morning, the exact hour being set at eight.

BARTHOLOMEW NOW HEADS KENTON CLUB

COLUMBUS, O., May 17—One of the most energetic of the smaller clubs in Ohio is that of Kenton. The annual meeting has just been held and as a result W. E. Bartholomew is now at the helm as president. He is one of the most extensive onion growers in the country and is an enthusiastic automobilist.

TROY CLUB STARTS MEMBERSHIP CAMPAIGN

TROY, N. Y., May 31—It has been estimated that there are about 270 automobile owners in this city, and the Troy Automobile Club has set about to enlist every one of them. This organization, which was formed in 1904 and re-organized in 1908, has about 50 members at present and is active in its work for the improvement of conditions in this locality towards the autoists. At present a set of street regulations are being compiled and it is believed that they will be adopted by the police department. These give definite rules for all vehicles, as to turning, keeping to the right, stopping, etc., much similar to those recently put in force with success in Albany. Orphans' Day will be celebrated on June 2, taking the children to Rensselaer Park for an afternoon, after a parade through the city.

The officers of the club are: President, F. B. Twining; vice-president, E. S. Platt; secretary-treasurer, Alonzo McConihe; board of governors, LeG. C. Cramer, H. S. Ide, John McGlynn, J. J. Murphy, R. C. Reynolds, J. J. Smith, John Squires, Dr. L. R. Whitney, and the other officers.

HARTFORD CLUB IS IN A FIX

HARTFORD, CONN., May 29—Aside from awarding the Maxwell Junior and the Renault a cup each for winning in their respective classes in the recent reliability run, the Contest Committee of the Automobile Club of Hartford is rather up against it. It was proposed that the class trophies be melted up and medals made from the material; then it was suggested that the lucky ones to finish with clean scores draw lots, the winner to take the cup, but this was regarded as a rather unsatisfactory scheme. In all probability cups for classes with several perfect scores will be redeemed and the equivalent in money expended for suitable medals, all of which will be the same. It is rather a coincidence that the best drivers in the run numbered among those who stalled motors. The clean score of the Interstate car has been questioned. On the last lap Mills, the driver, claims he turned his car into the ditch to prevent a collision, thereby damaging the oiling system. This he repaired and the referee awarded him a clean score.

ITHACA CLUB MAKES A GOOD BEGINNING

ITHACA, N. Y., May 29—By holding a very successful banquet and smoker at the Dutch Kitchen, the recently organized Automobile Club showed some signs of life and made a noise like a good beginning. Toastmaster J. M. Clapp presided and brief addresses were made by President Thomas W. Mone, Daniel Rothschild, C. S. Ricker, James A. Causer and others. One fact dwelt upon was that the Ithaca club, while the youngest in the State, has already discounted many of the older organizations in point of membership. The charter officers are, besides the president: Vice-president, Daniel Rothschild; treasurer, E. N. Jackson; secretary, J. A. Causer. These officers, together with R. A. Heggie, D. E. Marsh and C. W. Fletcher, constitute the board of governors.

OGDENSBURG AUTOISTS FORM CLUB

OGDENSBURG, N. Y., May 24—Automobile owners of this city have formed a temporary organization looking to the establishing of an automobile club, and at a recent meeting the following officers were elected: President, Walter G. Kellogg; vice-president, Charles D. Randles; secretary, Thomas H. Lawrence; treasurer, Dr. A. E. Haynen; governors, George R. Malby, Edgar A. Newell, George F. Darrow. There are 51 automobiles in the city, exclusive of those owned by garages.

Latest Production of the Moon Motor Car Company

The above photograph just received from the St. Louis factory is of Model C, a new Moon car with baby tonneau, equipped with a Victoria top. In keeping with the others of the Moon line, it is attractive in appearance and will undoubtedly prove a ready seller.

PALACE SHOW TO OPEN NEW YEAR'S EVE

Opening the Grand Central Palace Show of the American Motor Car Manufacturers' Association on New Year's Eve proved so successful last Winter that the show committee, of which R. E. Olds is chairman, has decided definitely on that date as the time for the opening of the "Decennial Show" of 1910. There will be the usual private view in the afternoon of Friday, December 31, 1909, with the formal opening at 8 o'clock on New Year's Eve, after which the show will continue until the following Friday night.

There will be some changes in Grand Central Palace which are expected to supply additional space to care for those exhibitors who could not be provided for at the ninth affair, and it is believed that the Tenth International, or what will be known as "The Decennial Show," will surpass in attendance and sales even the record-breaking affair of last Winter.

BROOKLYN SCIENTISTS LISTEN TO EXPERTS

Automobiles considered from the standpoints of economy, technique and sport were the subject of a series of illustrated lectures before the Brooklyn Institute of Arts and Sciences, at the Academy of Music in that city, on the evening of May 27. The speakers were Herman F. Cuntz, M. E., of the A. L. A. M., who spoke of the economical progress made in the industry; Alexander Churchward, secretary of the Society of Automobile Engineers, who treated the subject from the technical standpoint, and Orel A. Parker, of the Automobile Club of America, who spoke on the subject of the sport in its various phases. The attendance was large and much interest was manifested.

POPE REDEEMS NOTES AHEAD OF TIME

HARTFORD, CONN., May 29—As an evident hallmark of prosperity, it was announced to-day that the Pope Manufacturing Company, of this city, has issued a notice to noteholders that the rest of the outstanding paper will be taken up on July 1. These are the first and second issues, the third having been redeemed on January 1 last, two years and five months before maturity. A similar policy of early redemption has been pursued with the others, and they will be paid thirteen months and one month, respectively, before due. The resumption of the immense Pope business of several years ago has made this possible.

ELECTRIC VEHICLE CO. MAY LOSE RECEIVER

HARTFORD, CONN., May 29—Business has been so good lately that it is now stated on good authority that the complete reorganization of the E. V. Company will soon take place. Nearly all of the claims have been settled and the controlling interests will be able to start with a clean slate. The local interests welcome the good news and hope to see the deal consummated early.

THE DINNER TO CARLTON R. MABLEY

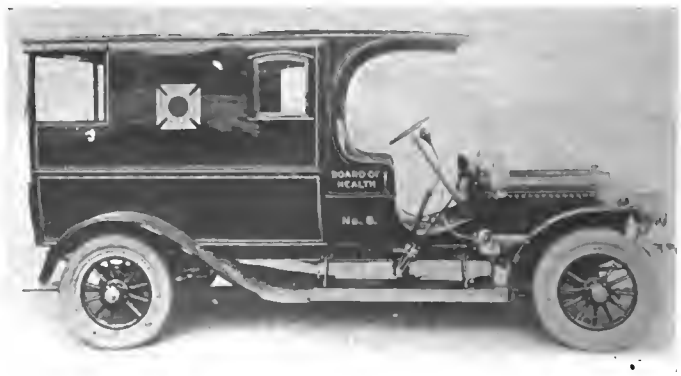
One of the real veterans of the automobile trade, Carlton R. Mabley, was the guest of honor at the dinner of the Fairweather Club, held at Reisenweber's, New York City, Wednesday evening, May 26. H. L. Humphries, of the automobile department of the New York *Evening Post*, was responsible for the successful recognition of Mr. Mabley as one of the prominent early factors in blazing the auto trail in the metropolis. The firm of Smith & Mabley had an international reputation, due principally to the efforts of the guest of the occasion, who accepted the encomiums thrown at him from all directions with characteristic modesty.

Peter Fogarty, as toastmaster, contributed Milesian wit in his introductory remarks for the various speakers. The list included H. L. Bridgman, hero of Arctic explorations, and C. F. Wyckoff, who accompanied him on one occasion; Creswell McLaughlin, the well-known "Schoolmaster of Cornwall-on-the-Hudson"; Winthrop S. Scarritt, well supplied with word pyrotechnics; Herman F. Cuntz, with an interesting story on roads building; Henry M. Duncan, whose rhythmic conversation flowed easily, and A. G. Batchelder.

The notables present included W. W. Burke, president of the Fairweather Club; Alfred Reeves, Coker F. Clarkson, Harry Fosdick, Louis R. Smith, W. T. Berrien, E. S. Partridge, A. J. Pickard, J. H. Gerrie, James C. Nichols, C. L. Simmond, H. T. Adams, C. W. Wurster, J. M. Lansden, William and Harry Knipper, L. C. Van Bever, E. H. Kidder, George S. Simpson, N. E. Neswold and M. J. Sullivan. Many absentees sent regrets, and their letters and a few marconigrams were read.

NEW TRUCK COMPANY GETS GOOD START

WORCESTER, MASS., May 29—A charter has just been granted to the R. L. Morgan Company, of this city, to manufacture motor trucks. Realizing the immense field which is only beginning to open up for motor-driven trucks, this company will start right in to build a good machine and build them in large numbers. About seventy-five men will constitute the working force at the start, which will be made in the large three-story brick building formerly occupied by the Crompton-Thayer loom works. Beginning with a large number of orders on hand, the production will be rapidly increased until the yearly production reaches 500. Back of the new enterprise are such sterling men as Ralph L. Morgan, the designer of the truck; Henry E. Whitcomb, director of the Merchants' National Bank; F. B. Durfee, treasurer of a local building company, and others. Mr. Morgan will be president, Mr. Whitcomb treasurer and manager, while Mr. Durfee will act as vice-president. The shop will be under John R. Back, with the F. E. Reed Company for thirty years.



Maxwell Ambulance Built for City of Newark

The photograph shows the new ambulance delivered to the City of Newark, N. J., by the Maxwell-Briscoe Motor Company. The wheelbase is 126 inches, and the body is seven feet in length, three feet wide, and the furnishings include stretcher, medicine chest, speaking tubes, and side seats which fold up when not in use. The inside of the vehicle is padded and electric lights are arranged for the convenience of the surgeon.

Stearns Cars Carrying Crippled Orphans to Coney Island

The line-up of twenty-five Stearns machines in front of the Crescent Athletic Club House, Brooklyn, where the crippled children from the Free Industrial School of New York were taken for lunch just previous to the pleasure trip to Coney Island.

New Factory for Rutenber Engine Makers—The Western Motor Company, of Logansport, Ind., is building an additional factory at Marion, Ind., which, with the present one, will be supplied with castings from the foundries in Logansport. The new structure will be built of reinforced concrete, two stories high, 450 feet long and 66 feet wide. Machine shops will occupy the second floor, and assemblying rooms, testing department and offices will be located upon the first. The 60,000 square feet of floor space thus obtained will be devoted entirely to the manufacture of gasoline motors of the Rutenber four-cylinder type and will materially increase the output of the company. It will be ready to start operations early in September.

Ferro Engines Outgrow Big Plant—Finding that an output of thirty engines a day is insufficient to fill orders, the Ferro Machine & Foundry Company has been obliged to add to its immense factory in Cleveland, claimed to be already the largest marine engine plant in the world. A three-story machine shop is now being erected, covering an area of 140 by 160 feet, and will be one of the most completely equipped in the country. Latest modern machinery and tools will be installed, including individual electric drives. A dining-room 40 by 140 feet in size is being built for the use of the employees, and a basement 80 by 140 feet will be fitted up as a store.

Velie Increases Factory—Operations have been commenced by the Velie Motor Vehicle Company, of Moline, Ill., upon addition to its factory. The new structure will measure 80 by 220 feet in size, with four stories and a basement, of reinforced concrete, and will cost about $100,000. Another story will also be added to the present plant, so that the whole will harmonize, for the new section will form a wing of the old one. An output of ten cars a day is now that of the factory, employing over one hundred men, and it is stated that orders are being received faster than filled.

Republic Tire Output Increased—Staggard tread tires, made by the Republic Rubber Company, in Youngstown, O., have been in such great demand of late, according to the company officials, that the force has had to be doubled and a large night shift employed in order to supply the demand. The Staggard tread has become a feature of the Republic output, for the rubber protuberances act as skidding preventatives, while at the same time are large enough to make the tire good in dry weather also.

Bids Asked for Autos to Carry Mail—So successful has been the test of automobiles in New York mail service that Postmaster Morgan has asked that the service be increased, and the Government has asked for bids for automobiles. These will be received by the Postoffice Department in Washington, and are to cover a period from July 1, 1909, to June 30, 1913. Lines are expected to be established in the uptown districts to carry mail to stations which have pneumatic tube connection with Grand Central and the general postoffice.

Fisks on Winners at Yale Hill Climb—Fisk tires and Fisk removable rims scored in the recent hill climb of the Yale Automobile Club, on the Shingle hill at New Haven, Conn. The Knox cars, which were driven by William Bourque and Albert Dennison, carried Fisk equipment and they made the fastest time of any American cars and won in their classes.

IN AND ABOUT THE AGENCIES

Interstate, Chicago—The Interstate Motor Car Company, which has filed papers for its incorporation, will handle the product of the Interstate Automobile Company, of Muncie, Ind., in the Windy City. Temporary quarters have been engaged by E. C. Lester, who is in charge, at 1328 Michigan avenue, but a long-term lease has been closed for property at 2425 Michigan avenue, and as soon as this is cleared a three-story building will be erected. The move of the Interstate to that section of automobile row, south of Sixteenth street, will take it into the proximity of the new homes of the Locomobile, Stearns, Premier, Packard and others. The building will be 161 feet deep and 25 wide, with the front for use as a salesroom, while the rear will be for a garage, and additional salesrooms and offices will be placed upon the second floor. The third will be used for equipment and shop departments.

Hoyt Electrical Instrument Works, New York—Additional space has been found necessary by the New York office of the Hoyt Electrical Instrument Works, of Penacook, N. H., and it will be moved on June 1 from 1931 Broadway to 136 Liberty street.

RECENT BUSINESS CHANGES

American Oil Engine Company May Move—It is believed in Poughkeepsie, N. Y., that the Adriance building on North Water street will be taken over by the American Oil Engine Company, now located in Connecticut. The negotiations are being made through the Chamber of Commerce. The concern manufactures stationary, marine and automobile engines in which kerosene is used as fuel.

Automobile Maintenance Company Changes Name—The Automobile Maintenance Company of Chicago has changed its name to the Automobile Maintenance and Manufacturing Com- Engine Company, with a capital of $25,000.

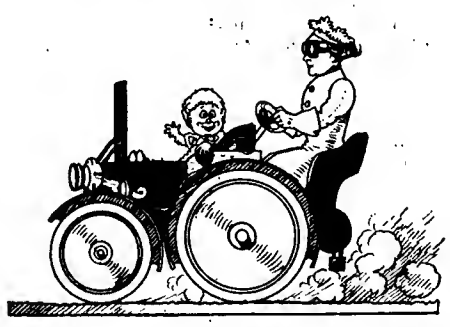
Homer Auto Truck Company Changes Name—The Homer Auto Truck Company of Lansing, Mich., announces the change of its name to the Homer Gas Engine Company. with a capital stock of $25,000.

CAMERON CO. CONSOLIDATION

BEVERLY, MASS., June 1—The Cameron Motor Company, organized last fall with New York capital to control the output of Cameron cars from the factories at Beverly, Mass., and New London, Conn., has been absorbed by the old company. The capital of the Cameron Car Co. of Beverly, Mass., has been increased to $500,000 and the affairs of the enlarged organization will be handled by E. S. Cameron, general manager; W. T. Marsh, treasurer, and H. W. Doherty, sales manager.

All four-cylinder models will be built in the Beverly plant; the sixes in New London; and by the acquisition of W. T. Marsh, who is the controlling factor in the American Motor Co. of Brockton, Mass., manufacturers of motorcycles, Cameron gains the assistance of a third plant, where larger quantities of smaller parts will be manufactured.

Arrangements are being completed for an output of 5,000 cars between September 1, 1909, and July 1, 1910.



If we must have lady chauffeurs, what's the matter with this?—From "The Auto Era," published by the Winton Motor Carriage Company, Cleveland, O.

PERSONAL TRADE MENTION

E. Mack Morris has accepted a position as general manager of the Model Automobile Company, of Peru, Ind., manufacturers of Great Western cars. Mr. Morris has been connected with the sales force of the E-M-F Company until recently, and previous to the formation of that concern was assistant secretary of the Northern Motor Car Company. As

E. Mack Morris

general manager of the Model Company he contemplates the building of 1,500 cars during the coming season. Mr. Morris succeeds E. A. Myers, who is general manager of the gas engine works and who found his double duties too great to give both proper attention.

F. H. Fowler, well known in New England automobile sales circles, has joined the forces of the Siro Carbureter Manufacturing Company, of Springfield, Mass., as general salesman.

Alexander Schwalbach has joined the forces of the J. S. Bretz Company of New York, as advertising manager. Mr. Schwalbach until recently has been associated with W. J. Morgan.

W. G. Jennings has been appointed manager of the Detroit branch of the Diamond Rubber Company, located at 265 Jefferson avenue.

TAXICABS AND TRANSIT

Savannah, Ga.—The Savannah Taxicab Company has been organized and incorporated with a capital of $50,000 to operate taxicabs in this city. The first shipment will consist of fifty cabs, and this number will later be increased by another fifty, the first being scheduled to arrive within a couple of weeks.

NEW AGENCIES ESTABLISHED

Frayer-Miller: Cleveland—Auto Truck Sales Company, distributing to 17 adjacent counties, 225-227 Williamson building.

Royal Tourist: Houston, Tex.—Palace Automobile Company, Louisiana and Rusk streets.

Autocar: Chicago—Louis Gayler Company, 1532-4 Michigan avenue, with the Stevens-Duryea.

Interstate: San Francisco, Cal.—Burkett & Crippens, 550 Golden Gate avenue.

Unito: Cleveland—Auto Sales Company, in addition to the Hupmobile.

RECENT INCORPORATIONS

Cabell-Lincoln Rapid Transit Company, Huntington, W. Va.—Capital $10,000. To operate automobiles for transfer purposes. Incorporators: S. G. Griffith, L. H. Cammack, S. H. Bowman, H. S. Bryer, J. T. Calbert.

Automobile Wheel Company, Richmond, Va.—Capital $500,000. To manufacture automobile wheels. President, R. McC. Bullington; vice-president, D. A. Bottom; secretary and treasurer, A. E. Holdt.

Eastern Pneumatic Tire Company, Boston.—Capital $25,000. To deal in pneumatic tires. President, A. R. Ellis; vice-president, H. N. Atwood; treasurer, John McLay; clerk and attorney, R. F. Wight.

Newcomb Engine Company, Harrison, N. Y.—Capital $200,000. To manufacture motors, automobiles, engines, motor boats, etc. Incorporators: W. B. Thompson, O. A. Hack, E. C. Chamberlain.

Buckeye Machine Company, Dayton, O.—Capital $10,000. To deal in automobiles, athletic goods, etc. Incorporators: M. C. Gath, P. D. Gath, E. L. Kincaid, W. V. Crowe, N. G. McCartney.

Atlantic Automobile Company, Atlantic City, N. J.—Capital $25,000. General automobile and garage business. Incorporators: C. E. Schroeder, G. W. Meredith, F. A. Broadhead.

Cooke, Fitz & Dillingham Company, Portland, Me.—Capital $25,000. To manufacture and sell automobiles. President, C. E. Eaton; treasurer, T. L. Croteau; clerk, J. E. Manter.

Auto-Tri Manufacturing Company, Buffalo.—Capital $200,000. To manufacture, repair, rent, and sell automobiles. Incorporators: G. R. Bidwell, W. S. Bull, W. M. Bowen.

Oeson Automobile Company, New York.—Capital $10,000. To manufacture automobiles, parts and accessories. Incorporators: H. M. Kilborn, W. E. Matterson, Richard Sutro.

Fulton-Zinke Company, Chicago—Capital, $50,000. Manufacturers' agents for automobiles and accessories. Incorporators: A. W. McGovern, F. C. Rathje, H. C. Calhoun.

Plainfield Auto Sales Company, Plainfield, N. J.—Capital $25,000. To deal in automobiles and supplies. Incorporators: Dr. S. A. Aldrich, C. C. Brown, C. C. Rocap.

Touring Club of America, Hackensack, N. J.—Capital $10,000. To publish information for automobilists. Incorporators: G. L. Burlew, A. L. Westgard, R. S. Finney.

Economy Motor Buggy Company, Joliet, Ill.—Capital $60,000. To manufacture and deal in automobiles. Incorporators: J. F. Beuret, H. L. Thompson, J. C. Flowers.

Rutherford Transit Company, Rutherford, N. J.—Capital $20,000. To operate an auto stage line. Incorporators: William Black, C. R. Soley, J. M. Bell.

Rae Electric Vehicle Company, New York City—Capital $150,000. To manufacture and deal in motor vehicles of all kinds. Delaware corporation.

Yonkers Auto Station, Elmsford, N. Y.—Capital $10,000. To maintain a garage. Incorporators, A. S. Thomson, David Scotland, F. T. Lewis.

Phineas Jones & Company, Newark, N. J.—Capital $100,000. To manufacture wheels, hubs, and tires. Incorporators: H. P. Jones, P. Jones.

Lowell Taxicab Company, Lowell, Mass.—Capital $10,000. To do a general automobile business. Incorporators: F. E. Haines, F. B. Emerson.

Polk-McKinney Automobile Company, Little Rock, Ark.—Capital $10,000. Incorporators: Eugene Polk, Roy McKinney, Roy W. Martin.

No-Shaming Company, Cleveland.—Capital $10,000. To deal in automobile supplies and specialties. Incorporators: L. Daniel and others.

Terre Haute Automobile Company, Terre Haute, Ind.—Capital increased from $10,000 to $30,000. President, Fred B. Smith.

RECENT PUBLICATIONS

Ross Gear & Tool Company, Lafayette, Ind.—Steering gears for touring cars, trucks, roadsters, runabouts, motor boats and motor buggies, and rear axles for delivery wagons and motor buggies, made by the Ross Gear & Tool Company, Lafayette, Ind., are illustrated in the new catalogue issued by this concern. Four types of steering gears are manufactured, one for use on three and five-ton trucks, weighing 80 pounds; one for trucks of one and one and a half tons' capacity, weighing 38 pounds; practically the same one as the latter for use on heavy runabouts and touring cars; and the fourth for use on light delivery wagons, runabouts, and motor buggies. Features of the Ross gears are their large bearing surfaces, elimination of points, lines, and small surfaces of contact. They are oil tight and dust proof. The rear axle assemblies are made with spiral gears which will coast as easily as ordinary bevel gears or chains. The sets of ball bearings are used and the differential is of the bevel gear type. A specialty is made of cutting bevel gears.

S. F. Bowser & Co., Fort Wayne, Ind.—Under the interesting title of "The Law's Demand," S. F. Bowser & Company are sending out a little book of eight pages descriptive of the storage gasoline outfits made by them. Outfit No. 41 describes the long distance arrangement with tank underground and pump in the building. No. 47, on the same style, is for smaller places such as private garages. Nos. 45 and 46 are self-contained and are designed to be buried alongside of the driveway or near temporary residents. The latest product is the cabinet in which is combined the business end of both the gasoline and oil storage outfits. This is a handsome cabinet, arranged in any desired finish and gives to the garage those finishing touches which only equipment and furniture of beauty and refinement can give. The title of the book comes from the fact that nearly all of the larger cities have very rigid laws against the surface storage of gasoline on any other method than underground storage.

W. H. McIntyre Company, Auburn, Ind.—The advance sheets of this firm's 1909 catalogue show that by the addition of Model 200 express wagon, the line of high-wheeled cars is complete. It includes buggies, surreys, limousines, runabouts, one, two and three-seated pleasure vehicles, express wagons, mail wagons, open and covered delivery wagons and others. The power varies according to the nature of the car and the work to be done; two-cylinder 10-horsepower up to four-cylinder 28-horsepower, all air-cooled. The new Model 200 has a two-cylinder 4¾ x 4¾ air-cooled motor, rated at 16-18, 100-inch wheel-base, two spread planetary transmission, double chain drive, 38-inch wheels with 1½ solid tires, and weighs 1,800 pounds.

Williams Foundry & Machine Company, Akron, O.—Akron clutches for factory line shafts and power transmission machinery are described in a 28-page catalog published by the Williams Foundry & Machine Company, illustrating the use of friction disc couplings. The advantages accruing from their use, such as separation of the various parts of the shafting for repairs, or when not in use, without disturbing the other departments of a plant, are explained at length. Nineteen sizes are made, with capacities of from ¾ to 1,000-horsepower at 100 r.p.m. Compression grease cups are also made.

Grabowsky Power Wagon Delivers Lorain Hose Cart Over Roads

New uses are continually being found for commercial motor-driven vehicles, and one of the latest is the delivery of fire apparatus over the roads from the makers in one city to the users in some other. In this case a Grabowsky power wagon pulled a hose cart from Cleveland to Lorain, O., a distance of 30 miles, over very rough roads. There were no delays, and the time was but a few hours, which is slight as compared with the time it would have taken horses to do the same work.

Information for Auto Users

Michelin Plastic Cement—There may be other parts of the car which get more attention than the tires, but there is no other part which deserves as much of the autoist's attention. Thus, the owner and driver should watch his tubes and shoes, the latter for cuts caused by glass or pointed stones, the former for signs of injury due to punctures or other causes. These places in the fabric should receive immediate attention, and in this way dirt or moisture is prevented from working into the ragged openings, where it can do the maximum amount of damage. A very satisfactory preparation for effecting permanent repairs in all makes of tires is the new cement, Michelin Mastic, made by the Michelin Tire Company, with an American factory located at Milltown, N. J. This is not a liquid, but a plastic cement, and is put up in one and two-ounce cans. Its use is economical, as a very small quantity is required at any one time, nor does it deteriorate with age. Its use is simplicity itself, and with the instructions furnished by the makers the veriest novice can preserve his tires with it. It is equally serviceable for repairing punctures along the roadside.

MICHELIN CEMENT.

Tucker Self-Locking Grease Cup—As the use of compression grease cups increases, being now used on practically every part of the car not supplied from a lubricator lead, more thought is being given to the design and construction of these simple lubricating devices. One of the newest ideas is a profanity saver, all right, for a grease cup without a cap is worthless, and the loss of caps is a frequent happening. The cups now being marketed by the firm of W. W. & C. F. Tucker, Hartford, Conn., have a simple locking device, which prevents these losses. The lock is placed on top of the ordinary cup in the handiest possible position. To unlock it all that is necessary is to push the small additional top part downward and turn to the right, which turn locks it open. After filling the reverse operation suffices to lock it in the closed position. Tuckers make a number of other styles of grease and oil cups, but the positive locking device is given preference over all of the others because of the much greater demand for this very superior form.

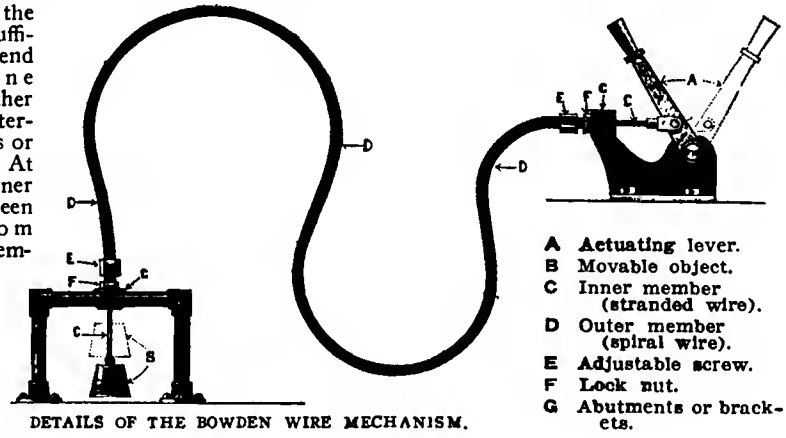
TUCKER SELF-LOCKING GREASE CUP.

Bosch Steering Wheel Switch—Many an automobilist has wished for an easily applied steering wheel switch of the push-button type, and now this may be had in such shape as to permit of its attachment to any steering wheel, and so plain as to allow of the work being done by any one. It may be used for opening or closing the ignition circuit for starting and stopping the motor, or for use with an electric signalling horn. It consists of a nickel-plated body and a head of hard fiber. The body is provided with one flange and a thread, upon which another flange in the form of a nut provides a variable means of fastening the device to the wheel. The internal construction is such that it may be placed with the button head either above or below the spokes of the wheel, as desired. It is made and marketed by the Bosch Magneto Company, which has its main American headquarters at 225 West Forty-sixth street, New York City.

Novel Form of Controlling Mechanism—With the view of supplanting the usual rod and rocker connections for controlling the throttle, spark or auxiliary air valve on automobiles, motorcycles and motor boats, and of saving time in the installation of control devices when assembling, the Bowden wire mechanism was first introduced, and its popularity and suitability for such purposes is shown by its widespread adoption in Europe at the present time.

The mechanism consists of but two parts, a closely coiled and practically incompressible spiral wire, constituting what is termed the "outer member," and a practically inextensible wire cable threaded through the above and termed the "inner member." The operation of the mechanism is as follows: Imagine two points, one where there is an object to be moved and the other where the necessary power is to be applied. In the sketch DDD is a length of the mechanism sufficient to extend from the one point to the other around any intervening corners or obstacles. At CC the inner member is seen emerging from the outer member and attached at one end to the actuating lever, A, and at the other to the object to be moved, B. The outer member is anchored at GG, which anchoring points may be placed wherever convenient. If the lever, A, is now operated, the movement is at once imparted to the other end of the inner member, the outer member exhibiting a wriggling movement at the curves as the inner member attempts to straighten out and is prevented from doing so by the outer member, which cannot shorten, at is is anchored at both ends. The dotted lines show the lever A in its actuated position and the object B correspondingly raised. Adjustable stops, EE, are provided, the extension or screwing out of which is equivalent to lengthening the outer member, thus compensating for any settling or "bedding down" of the inner. These stops are held in position by lock nuts, FF. The sketch shows the form most in use, a pull being obtained in this arrangement. If a pushing motion is desired the inner member is anchored and the outer member attached to the lever, while if neither member is anchored, but both are fixed relatively to each other, when one pulls the other pushes and a relative displacement is thereby readily obtained.

The wire is made in a number of styles of finish to correspond with the plating on the car and for either external or internal use. Various controlling levers, brakes and attachments for use with the mechanism are also manufactured. The Bowden wire output is controlled by the J. S. Bretz Company, of New York City, which has the sole selling rights for America.



DETAILS OF THE BOWDEN WIRE MECHANISM.

The Autoist's Old and Good Friend—Probably the first automobilists used in their gear cases the same lubricant that is so widely used now, Albany Grease. This is made by Adam Cook's Sons, New York City, and the distinctive trademark of the boy sliding down the plank is perhaps as well and thoroughly known as any one part or accessory entering into the construction of the whole car. This old-established lubricant is now made in no less than seven densities, for as many purposes. These are both numbered and lettered, according to advancing density, from o to 3 and X to XXX. The grease may be had in one, five, ten, twenty-five and fifty-pound cans, as well as kegs containing 125 pounds. As it is impossible to churn or agitate this product so as to cause it to lose its density, it is asserted that the use of it is a source of marked economy. With the increase in the already large number of places on an automobile which are lubricated, an old standby in lubrication like this is widely appreciated.

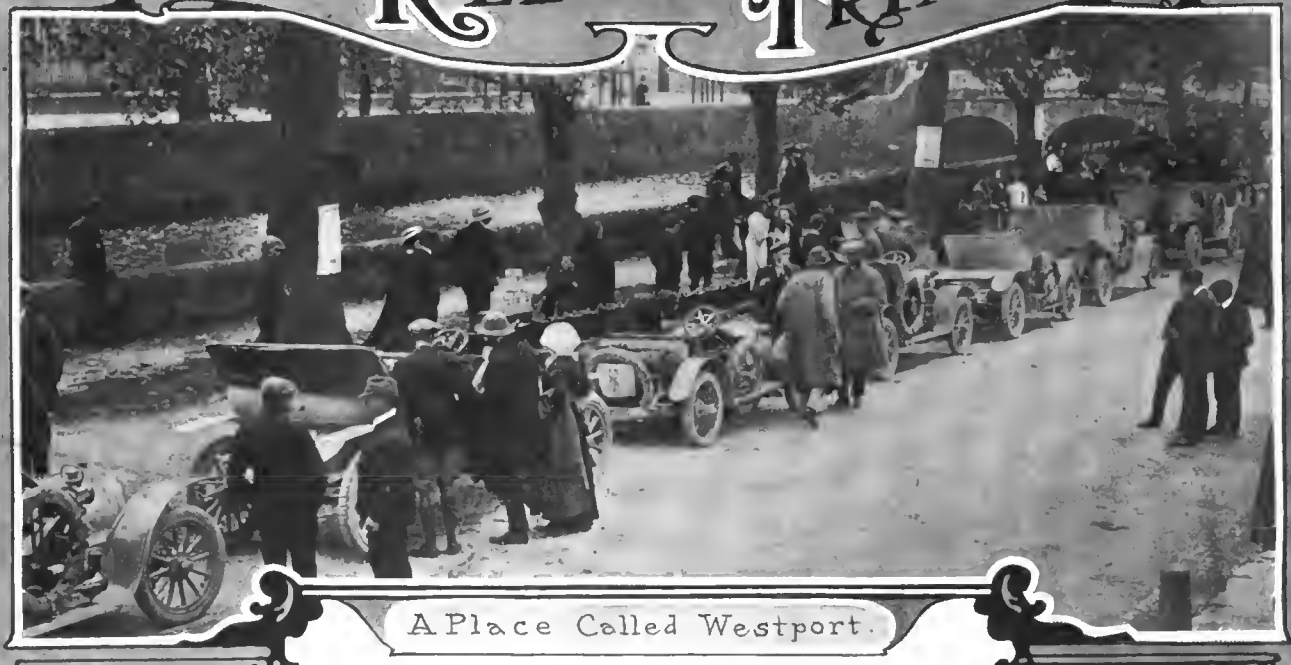
IRELAND'S RELIABILITY TRIALS



A Place Called Westport.

DUBLIN, May 23—Nigh onto a thousand miles of the hardest roads, steepest hills, and most beautiful scenery of Ireland, famous for all three, constituted the task set the fifty and odd starters in the Irish reliability trials, which started on May 26 and continued excepting Sunday, May 30, until June 1. In this week

Marlborough Car Climbing Speencgue Hill, from Which a Beautiful View of Ireland's Charming Lakes Is Obtained

with six days of hard work was crowded a complete circuit of the Emerald Isle, with its attendant difficulties, to say nothing of very sharp competition among the contestants, and all the discouragement possible from the very frequent rains.

The trials really started in Dublin, Tuesday, when the contesting cars were officially received, measured and weighed. The rules required certain maximum and minimum body dimensions but the weight was only restricted as to upper limit. The body sizes came near disqualifying two cars, the 15-horsepower Deasy being a quarter of an inch short at the back height of the tonneau. This was fixed to conform with the rules by removing the leather upholstering and adding a piece of wood, upon which the leather was replaced. Another prospective contestant, the Adler, was disqualified for being below official dimensions.

After measuring, the cars were emptied, and weighed. Then they were parked for the night at Ball's Bridge, under the care of the Irish A. C.

Tuesday morning, the cars began upon the first day's share of the circuit, the run being from Dublin northward to Ballycastle, then west to Portrush, following the east seacoast for the first 50 miles. The whole distance for the day was 177¾ miles.

On the Way to Dundalk—Deasy Car in Foreground

and this was followed by an easier day of but 160 miles to Bundoran, via Londonderry, near which a stop was made for the hill climb. This was up Greenane hill, and was preceded in the morning by the speed tests on Magilligans strand, just out of Portrush. Although shorter in miles than the day before, this was no snap, the winding roads around dangerous points, and the passage through Barnesmore Gap, before reaching Donegal, being such as to test the car's and the driver's ability.

Friday, the cars that had survived up to that point, traveled on to Galway by way of Swineford, and along the west coast with a side trip to Ballinarinch, where a beautiful view of the Atlantic Ocean was obtained. This made a run of 165½ miles, and gave the survivors a total of 503 miles.

Galway-Killarney gave the tourists the easy day up to then, the length of the course run over being only a distance of 146 miles, down the west coast, with a slight detour to pass through Limerick, where the noon stop for lunch was made.

The day's rest, over Sunday, at Killarney was augmented on Whit-Monday when the itinerary included the easiest, and by far the most pleasant trip of the trial, the circular run around the lake region. This is easily the most beautiful part of the country and although in a race, the magnificent scenery was enjoyed by all, particularly by the Limited Section, which included all of the private owners and drivers.

To offset the two days' rest, if it might be called that, the concluding day put the cars through their paces, being by far the longest, 187 miles of varying degrees of severity, and all of it such as to give the driver no moment of security. This took the contestants across the southern end of the island back to the starting point at Dublin.

The cars were well distributed through eight classes in the first section, open to all comers, and the second or limited section, which was restricted to *bona fide* members of recognized clubs, besides which the cars had to be driven by the entrant or a member of his immediate family. Nor was a professional driver allowed on the cars of this class, even as a passenger. This class was well patronized, 9 of the 54 entries being included in it, of which two did not start, one of these being the 16-20-horsepower Argyll in the limited class.

There were several notable additions of newcomers and a few

prominent absentees. Among the latter were the Swift cars which for the last two years have taken such a prominent place among the high score cars. The entry in Class A of the two Bedford cars was of great interest and their successive good performances were closely followed, for these cars were of a new design, frankly and avowedly copied after American lines. The two Bedford entries had four cylinder engines of 95 mm. (3¾ inch) bore and stroke. A planetary transmission in combination with shaft drive to the live rear axle was used. The other newcomers, whose entry attracted much attention, were the two-seated 12-14-horsepower Marlborough cars entered in Class C1. These weighed but 15 cwt. and carried four-cylinder engines of 80 mm. (3⅛ inch) bore and 100 mm. (4 inch) stroke.

The American cars among the starters were four in number, all products of the Cadillac factory at Detroit. They were well distributed over the list of classes, beginning with a single cylinder 10-horsepower in Class B, and including two 20-30-horsepower models in Class D, in which they competed with England's best in the small car line, most of the cars being of lower horsepower rating. Section Two, the Limited Section, also included one of America's representatives, another 20-30-horsepower Cadillac car. There were, as a whole, very few cars other than English make, either of home design and manufacture complete, or foreign design and home manufacture. Thus, aside from the Americans just mentioned, there were but three French and one German car, the former being a Chenard-Walcker in the same class with the one-lung Cadillac, and a pair of Motoblocs in Class E. The sole representative of the Germans was the 30-horsepower Adler in Class F, where Talbot, Gladiator, Vauxhall, and Sunbeam supplied worthy competition.

The complete list of entries was as follows:

Class A—Little Briton, 10-horsepower; Little Briton, 10-horsepower; Bedford, 15-18-horsepower; Bedford, 15-18-horsepower.

Class B—Briton, 12-horsepower; Chenard-Walcker, 8-9-horsepower; Riley, 10-horsepower; Adler, 12-horsepower; Cadillac, 10-horsepower; Rover, 8-horsepower; Bedford, 15-18-horsepower.

Class C—Chenard-Walcker, 12-14-horsepower; Riley, 12-horsepower; Star, 12-horsepower; Humber, 10-12-horsepower; Belsize, 14-16-horsepower.

Class C1—Star, 12-horsepower; Marlborough, 12-14-horsepower; Marlborough, 12-14-horsepower; Chambers, 12-horsepower.

Chambers Car Mid Pastoral Scenes at Ballriggan

Class D—Talbot, 12-horsepower; Cadillac, 20-30-horsepower; Gladiator, 12-14-horsepower; Cadillac, 20-30-horsepower; Star, 15-horsepower; Straker-Squire, 15-horsepower; Rover, 15-horsepower; Rover, 15-horsepower; Humber, 16-horsepower; Humber, 16-horsepower; Mass, 15-horsepower.

Class E—Talbot, 15-horsepower; Vauxhall, 20-horsepower; Vauxhall, 20-horsepower; Vauxhall, 20-horsepower; Armstrong-Whitworth, 18-24-horsepower; Motobloc, 18-22-horsepower; Deasy, 15-horsepower; Motobloc, 18-22-horsepower.

Class F—Talbot, 25-horsepower; Adler, 30-horsepower; British-Gladiator, 18-24-horsepower; Vauxhall, 24-horsepower; Sunbeam, 20-horsepower.

Class G—Gladiator, 40-50-horsepower.

Section Two (Limited)—Metallurgique, 12-horsepower; Peugeot, 10-12-horsepower; Austin, 15-horsepower; Metallurgique, 18-horsepower; Marlborough, 15-horsepower; Argyll, 16-20-horsepower; Clement-Talbot, 20-24-horsepower; Cadillac, 20-30-horsepower; Germain, 22-horsepower.

Of these, all appeared at the starting line, ready for business, excepting only one Motobloc in Class E and the 16-20 Argyll in the section for amateurs, as well as the 10-12 Peugeot and 20-24 Clement-Talbot in the same class as the Argyll, which latter were withdrawn several days before the start.

Mass Car Has Interested Spectators as It Climbs Up the Slopes of the Famous Speenogue Hill

SAVANNAH HAS DOUBLE TIE IN FIRST ENDURANCE

SAVANNAH, GA., June 7—Double ties; Chalmers-Detroit and E-M-F in the first division and Packard and Acme in the second were the results of the first endurance run of the Savannah Automobile Club Monday between this city and Augusta, a distance of 135 miles. In the nature of a good roads campaign, in connection with the tide of enthusiasm for better highways now sweeping through the State, this event was begun with 17 automobiles, and 14 of these finished as contestants, the entire party being increased in number by additions from cities and towns along the route. At all points the purpose of the contest was fulfilled, for the inhabitants turned out in force, and wherever the subject of roads was mentioned there was always a hearty response in favor of anything which would hasten their coming.

A Rest of Two Hours at Picturesque Scarboro (Where Dinner Was Taken), Five Miles from Sylvania

The South has had no endurance contests of this kind, and the run of the Savannah club was organized with a maximum and minimum time schedule, no car being allowed to reach Augusta before 7 o'clock in the evening, while those reaching the finish after 8 o'clock were penalized 25 points, and any being over five hours late were disqualified. The rate of 25 points per hour was arranged, and only one car was disqualified for being late beyond the limit, a Buick driven by W. H. Connerat.

An early start was made on the morning of May 31 from Liberty and Bull streets, with the cars at intervals of 100 yards apart, following President Frank C. Battey's Stevens-Duryea, which acted as pilot and confetti car. As far as Montieth, which was reached at 6.55 A.M., the roads were through Chatham County and were fine, but from that point to Rincon the worst of the entire run were found. In attempting to dodge one of the holes on this, the Packard of N. G. Brown went in to the hubs, and it required the assistance of several cars and four mules to draw the machine out of the bog. Rincon to Springfield, 27 miles, was made in one hour and forty minutes, and when the latter was reached the whole town had turned out to greet the autos. Mayor McLoud joined the Savannah Club for the remainder of the trip. The pilot car took the wrong course after leaving Springfield, and about 15 minutes were lost in regaining the route. Harvey Granger's Stevens-Duryea lost its muffler at this point. At Sylvania, the county commissioners—S. B. Lewis, J. O. A. Enecks, and C. S. Zeigler—joined the club in three White Steamers, driven by W. J. Hilton, C. M. Hill, and J. J. B. Morrell. After a short stop there the club drove to Jacksonboro Bridge, five miles away, where a rest of one hour and a half was taken for dinner. Comparatively slow time was made through the sand and sharp curves of Screven county to the Burke county line, after which the route was found to be almost a boulevard.

Waynesboro was reached one hour ahead of time and the citizens crowded around the cars. With the addition of E. E. Chance, chairman of the board of commissioners, Sheriff S. G. Story and J. P. Palmer, superintendent of roads and bridges, the trip was resumed in a half an hour. Because of the good condition of the cars at this point, it was decided to abandon the schedule and make for Augusta in the shortest possible time. T. A. Bryson's Chalmers-Detroit 30 and C. Graham's E-M-F were the only cars in the first section which made the last stop within the scheduled time, thus winning their perfect scores.

In the second division N. G. Browne's Packard 30 and G. Mouro's Acme were the successful ones. President Battery was penalized 25 points in the first class and the others considerably more, but in the second class there were three cars which received but 25, the minimum penalty. Two Stevens-Duryeas and a Jackson, another Chalmers-Detroit, and a Franklin each received 50 points.

On Tuesday the Savannah club was taken to the Carmichael club for a real barbecue and for speeches by members of the Savannah club, as well as those from the Atlanta, Augusta, Waynesboro, and Athens, all on the subject of "good roads for Georgia." The time of the return trip to Savannah was optional to the tourists, some coming through on Tuesday night by moonlight and others on Wednesday morning. On the return trip Harvey Granger, in his Stevens-Duryea 60-horsepower, made the 135 miles in five hours and one minute, breaking the previous record of seven hours and a half. One cup was to have been given as a trophy, but now that four have come through tied

it is probable that a meeting will be called, and arrangements made to give four cups instead of one. Word has been received that the Motor Club of Augusta is now planning an endurance run to Savannah some time during the month, the date to be announced later.

Herewith is the summary of the run:

FIRST DIVISION

Name of Car	H.P.	Cyl.	Model	Entrant	Driver	Penalty
Chalmers-Detroit	30	4	30	T. A. Bryson...	Bryson	Perfect
E-M-F	30	4	30	C. Graham.....	Mosher	Perfect

Meet at Fitzgerald, Ga., Is Postponed

SAVANNAH, GA., June 5—The three-day race meet scheduled for June 15, 16, 17 at Fitzgerald has been postponed until the middle of August. The reason is because the roads just graded are too soft for safe speeding, and with sixty more days in which to work on them the course will be in perfect condition.

SAVANNAH STILL HAS GRAND PRIZE HOPES

SAVANNAH, GA., June 5—More hope is now entertained for a grand prize race in Savannah than at any other time. A special meeting of the Savannah Automobile Club has been called, and a letter received from the Automobile Club of America will be submitted and gone into thoroughly. It is this letter that has caused the Savannah Automobile Club to feel that there will be a race, though if a race is to take place it will have to be decided upon at once, so as to give the manufacturers a chance to prepare special cars. It is probable that a committee composed of Mayor Tiedeman, President Battey, Harvey Granger, and two others will leave no later than Wednesday for New York, where they will talk over plans for the last time on the Grand Prize race.

READVILLE RACES BEING WELL ENTERED

BOSTON, June 7—Enough entries have already been secured for the races to be held at Readville track, June 17, to insure the success of the meeting. A contract has been signed by Ralph DePalma, driver of the Fiat *Cyclone*, and Charles Basle, driver of the Renault racer, for a match event of 25 miles. The other principal event will be the 25-mile contest for the Harvard trophy, with $800 additional in cash to the winners of first, second and third places. Basle and DePalma will drive in this race. There are six other events, and among the cars that have been entered are: Stearns, Allen-Kingston, Alco, Chalmers-Detroit, Knox, Columbia and Morse.

The Morse is a new car built in Boston and will make its début at Readville.

HARTFORD SOLVES ENDURANCE RUN TIE

HARTFORD, CONN., June 7—Copper trophies, thirteen of them, will be given by the Automobile Club of Hartford to those who made perfect scores in the recent endurance contest. There were 15 clean record cars but two of these, the Renault and the Maxwell Junior won their respective classes, leaving the bakers' dozen deadlocked. Albert M. Kohn, chairman of the contest committee in the absence of H. P. Maxim, is a manufacturing jeweler and he has arranged for the copper cups, each to be suitably engraved. In addition, a sterling silver club pin will be given to the successful drivers.

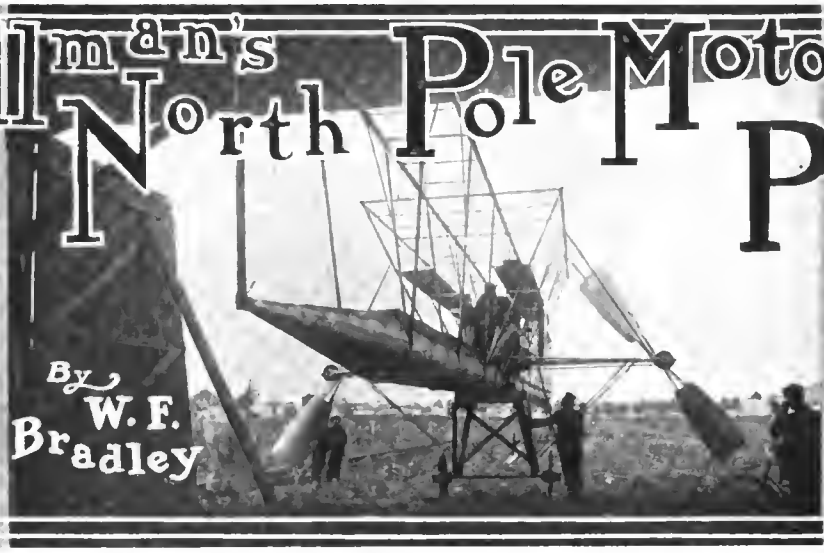
Wellman's North Pole Motoring Plans

By W. F. Bradley



Steel Car of Wellman Airship "America" That Is Fitting Out in Paris for the Perilous Trip to the North Pole

PARIS, June 3—Walter Wellman's first action on arriving in Paris was to visit the private workshop in the suburbs where, under the direction of Chief Engineer Melvin Vaniman and a group of American mechanics, the steel car of his airship *America* is being fitted out for its journey to the North Pole. Work is so far advanced that the ship will leave Paris very early this month for Spitzbergen, via Antwerp, to be followed by Walter Wellman, Melvin Vaniman, and the third member of the crew yet to be selected.

It is the same airship, modified and improved where previous experience has shown improvements were possible, which was used for the 1907 expedition to the Arctics. The steel car has a total length of 115 feet, and carries two gasoline engines, one an 80-horsepower four-cylinder model, driving two huge steel propellers, and the other a slightly lower powered eight-cylinder model driving a pair of wooden propellers capable of being pivoted on their axis in order to drive the airship horizontally or at any required angle from the horizontal.

Walter Wellman by the Side of His Airship

Some interesting tests were made this week with hydrogen gas as fuel. Normally the engines run on gasoline, of which 1,200 gallons are carried in the fourteen tanks forming the tubular keel of the ship. As this fuel is consumed, the weight of the airship will be reduced to such an extent that there will be hydrogen gas to spare. Instead of letting it out into the air, Engineer Vaniman has devised a system of burning it in the motors, a task which no other dirigible balloon pilot has attempted on account of the danger of fire.

Two carbureters are employed, one being an ordinary type working with gasoline; and the second a special appliance intended to mix hydrogen and air. Only one set of intake pipe are employed, arranged in such a way that a single throttle will allow of running entirely on hydrogen, entirely on gasoline, or on any proportions of the two. Experiments made at Spitzbergen in 1907 showed that the engine could be started much more readily on hydrogen than on gasoline. The tests this week further proved that the engines ran faster, with less vibration, and developed more power with the pure hydrogen mixture than with the best gasoline charge. Some further adjustments were required in order to make it possible to switch over from gasoline to hydrogen, or vice-versa, without a momentarily slowing down of the engine, but the value of the two fuels working together was undeniable. It was distinctly noticeable that the hydrogen mixture fired much more readily than the gasoline one, and that for a given number of revolutions the spark needed retarded less for the former than for the latter fuel. The experiments will be continued with a view to getting very accurate data on the hydrogen consumption per horsepower hour, as well as the best proportions of air for the two fuels.

JUST LIKE EARLY DAYS OF AUTO RACING

PARIS, June 3—The official opening of the Juvisy aerodrome, intended as the triumph of the aeroplane, and the inauguration of a period when flying machine races would supersede automobile speed tests, resulted in proving quite other things than the promoters had intended. Conditions of the aerodrome and its inauguration were ideal. The ground, situated about ten miles to the south of Paris, is a vast level field, surrounded by grand stand, aeroplane sheds, workshops, etc. For the Sunday inaugural meeting nine aeroplanes were promised, weather conditions proved to be ideal, and in the hope of seeing an altogether new sport a crowd estimated from 30,000 to 50,000 people traveled out to the aerodrome, filling every available space.

After two hours cooking under a hot sun, the easy-going spectators at last lost patience in the kite demonstrations, broke down the barriers and advanced in two solid masses across the field to inquire why they were not getting their money's worth.

The twelve mounted gendarmes were worse than useless, for they only served to irritate the people by their opposition, and for over an hour the officials were kept prisoners in their offices while the people outside clamored for the return of their money and let loose their wit at the expense of the organization.

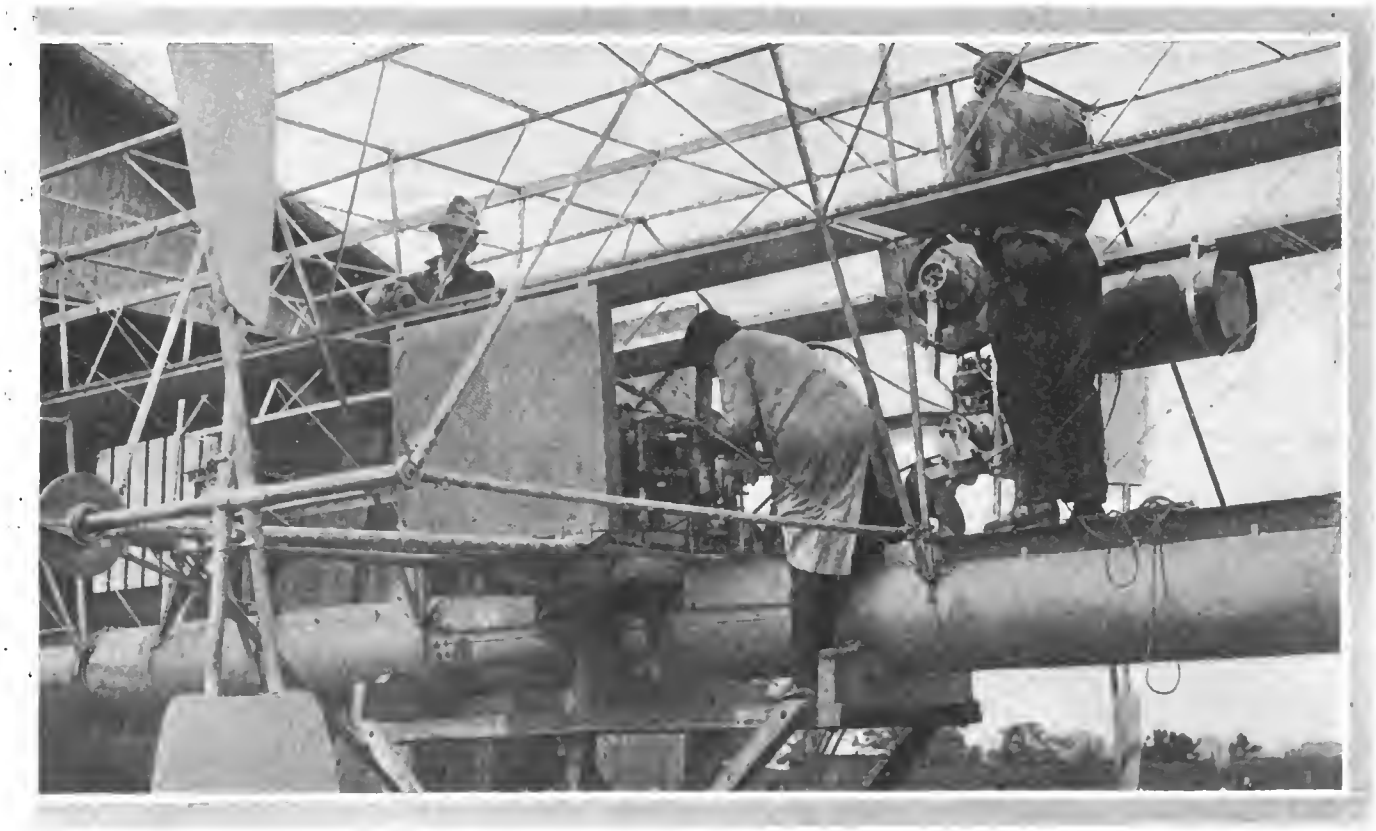
After considerable effort on the part of the police, members of the committee and self-enrolled guardians, the ground was sufficiently cleared to allow Leon Delagrange to get away on the old Voisin biplane with which he made his records in Italy last year. The flying machine, however, was not in a flying mood, the net result being a skim over the ground with an occasional jump into the air. The De Pischof, a badly executed copy of the Wright, was still less capable of flying, and after ten minutes on the ground was wheeled back to its shed and the shutters drawn down. Later Delagrange made further attempts, but his best performance was one round of the field, about three-quarters of which was in the air. Rougier, the ex-Dietrich race driver, who had made a flight of 25 miles the previous day, attempted to save the situation on his new Voisin flyer, but after one minute skimming the machine dived, sticking its nose in the soft ground and throwing its tail in the air. The driver was in no way injured, but his machine was too much damaged to make further flight possible.

Finally, when the spectators had gone home in disgust at the flying machines which were unable to fly in the gentle summer zephyr, Delagrange came out again on Captain Ferber's flyer and for ten minutes made a magnificent flight, at a height of about forty feet from the ground. It was too late, however, to undo the bad impression created, and in the minds of the Parisians the word aviator is synonymous with bluffer and the managers of the Juvisy aerodrome are guilty of getting money under false pretenses.

Making "Snake" to Be Used on Wellman Expedition

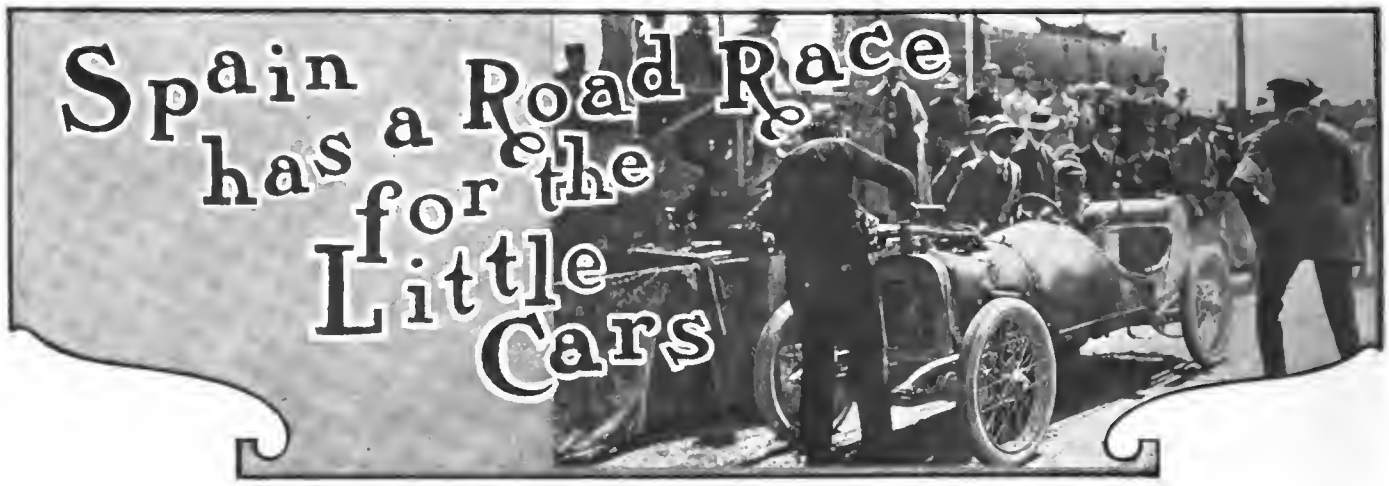
WRIGHTS WILL GET THEIR MEDALS TO-DAY

WASHINGTON, D. C., June 10—President Taft will to-day present to Wilbur and Orville Wright the gold medals of the Aero Club of America. In the morning it is planned to have a demonstration flight by one of the Wright brothers, if conditions are favorable, and at half past twelve a luncheon will be given the Wrights and the members of the Aero Club of America by the Aero Club of Washington, at the Cosmos Club. At half past two the presentation ceremonies will begin in the East Room of the White House, where President Taft will officiate. There will be present at the ceremony an array of Senators and Congressmen, the diplomatic corps, and the officials of the great scientific bodies of the country, making the assemblage one of the most brilliant and representative that has ever been seen in the national capital. The Aero Club of America, which has its headquarters at the New Willard hotel, is present in a body.



Engineer Vaniman Making Adjustments to Hydrogen Carbureter on Airship "America"

Spain has a Road Race for the Little Cars



Driver Goux Taking on Supplies for His Winning Lion Peugeot, in the Copa Catalunya, at Barcelona, Spain

BARCELONA, Spain, June 1—Automobile racing being dead in France, it rested with non-sporting Spain to bring it back to life with voiturette race that had all the interest and all the excitement of any of the large international events. The cars were twelve in number, with single cylinders of 3 9-10 inches bore, or the equivalent where multiple cylinders were employed, but were none the less interesting by reason of their smallness, for the French specialists have found the secret of developing 35 horsepower in this small diameter cylinder and of driving the cars at more than 50 miles an hour on level road.

Victory fell to Goux, on a two-cylinder Lion Peugeot of 3 1-10 inches bore by 7 4-5 inches stroke, with an average speed of 22.77 miles an hour for a distance of 225 miles. In considering the average it is necessary to take into account the fact that the course is less than 17½ miles round, that for a third of the distance it winds up a hillside, and that the frequent turns constantly kept the cars back.

Goux won the race with a large margin, for Georges Sizaire, who came in second, was 1 hour 19 minutes to the bad, but the race was none the less exciting for all that. On the first round Goux made the fastest time, covering the 17½ miles in 23.48, and being followed home by his team mate, Boillot, on a single cylinder car of 3 9-10 inches bore by 10 inches stroke, and a second car of exactly similar construction in fourth position, with Giuppone at the wheel. The only Spanish team in the race, small Hispano-Suiza four-cylinder cars of 2½ inches bore by 7 inches stroke, finishing third, fifth and sixth. Georges Sizaire, on a Sizaire—Naudin car of the same dimensions as the one-lunger, Lion Peugeots, broke a wheel on the first round, finishing in 1 hour 55 minutes 10 seconds, compared with 23 and 24 minutes for the first and second cars. It was a terrible handicap, and even the crack French driver appeared to look upon the task as hopeless, for, although he continued with his damaged wheel, he remained at the end of the list for the first five rounds.

But the Lion-Peugeot one-lungers were far too fast for the winding course, and after Boillot and Giuppone had both smashed their wheels on the dangerous turns and had been carried back to the grandstands on the rival but disabled Sizaire-Naudin, and after the same car had towed the damaged Demeester to the stands, Georges Sizaire came to the conclusion that something could be done. The rakish, big-bonneted blue car was jacked up, the damaged wheel replaced by a solid one, and with a handicap of 1 hour 50 minutes against him, Georges Sizaire rushed away at a speed of 55 miles an hour in an attempt to catch up with the flying and far-ahead leader.

First place at this time was being held by a four-cylinder Hispano-Suiza, with a similar car in second position and Goux's twin-cylinder Lion-Peugeot third. This latter had suffered serious damage to its radiator by a flying stone, and had to stop every eight miles to fill up with water. At half distance the Spanish Hispano-Suiza cars began to falter, two of them going out of the race and the third one being passed by the leaking Lion-Peugeot. Sizaire was now going all out, and, being slightly faster than the Lion-Peugeot, and not having, like this latter, to stop at intervals for water, was gradually lessening the distance between himself and the first car. Thanks to the dexterity of the Lion-Peugeot mechanic, the filling of the tank was a matter of seconds only, and with the big delay at the beginning Sizaire could not regain all of the ground that he had lost.

The race finished with Goux, on the two-cylinder Lion-Peugeot, first in 6.19.6; Sizaire, on single-cylinder Sizaire-Naudin, second, in 7.37.46 3-5; Soyez, on single-cylinder Werner, third, in 7.38 2-5, and Pileverdie, on a four-cylinder Hispano-Suiza, fourth, in 7.55.29.

This is the first time in any European voiturette race that multiple cylinder cars have made a really good showing. The reason of their victory lay entirely in the excessive speed of the single-cylinder models. The two Lion-Peugeot cars, with single-cylinder engines developing 35 horsepower, were too fast for the course, their disablement being caused entirely by the breakage of road wheels on turns. The handicap to the Sizaire-Naudin was exactly the same, and but for the hour lost on the initial round he would almost certainly have secured first place. The Sizaire-Naudin was a last year's car, while the Lion-Peugeots were all special productions, the single-cylinder models being very original by reason of their excessive stroke, high compression, high engine speed and three inlet and three exhaust valves spaced in a horizontal plane around the one cylinder.

The list of official observers for the Prince Henry tour reads like an extract from an army gazette, as the majority are officers and members of the general staffs of their countries. The German general staff will be represented by six majors, twelve captains and three lieutenants, besides which a great many other officers from different regiments will take part in this capacity, among them being Prince Franz Hohenlohe. With one exception the eleven observers Hungary is entitled to send are on the general staff, and this fact rather detracts from the character of the event as an ordinary tour, especially as permission has been granted for all to wear their uniforms.

The Swiss League Council is working at a set of uniform regulations governing motor traffic for the whole of Switzerland, as urgent representations have been made to this end by the hotel and inn-keepers of the republic, who are feeling severely the losses brought by the decrease in motor traffic. It was hardly to be expected that the automobiling public would calmly stand the hundred and one pettinesses of each canton and tiny parish without some return, and this took, to a great degree, the form of boycott.

Exhaust Side of Automobile Motors

By Thos. J. Fay

Part I

CONTINUING ON, from the fuel, after it has performed its quota of work, to the maximum possible extent, in view of the limitations imposed by motors, it becomes necessary to treat with the products of combustion, rather with the expectation that the mere question of noise and its elimination will not constitute the whole theme. This story of the exhaust will have to be divided up somewhat, owing to the differences that can be noted if the air-cooled problem is separately handled.

Exhaust Manifolds Used in Water-Cooled Motors—It was pointed out in the discussion of fuel how some designers attempt to gain power by inducing a vacuum in the exhaust manifold, and the question here is, how can the design be consummated in

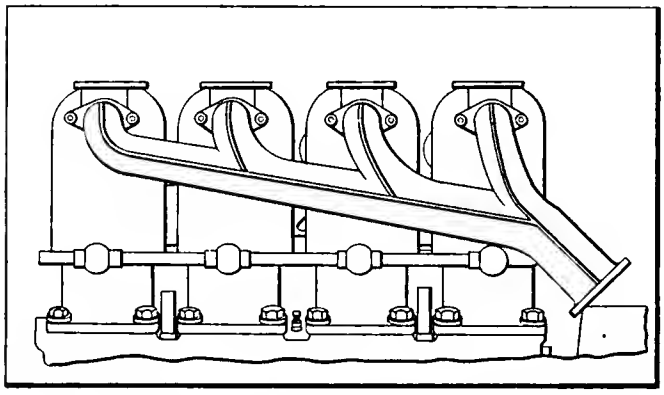


Fig. 51—Suitably proportioned exhaust manifold used on a two-cycle motor of the individual cylinder type

order not to lose power in the manifold? Certainly, it is important to avoid the loss of power due to imperfections in the exhaust manifold, even though it may not be easily possible to realize an actual gain, due to some method of creating a vacuum, in the absence of a condenser, which as yet has not been made to use in connection with the products of gasoline combustion.

It is not the purpose here to say that it will be feasible to condense the products of combustion, nor is it plain that there is much chance of gain by the introduction of an "air-pump" with the idea of axhausting the chamber to a point such as would result in a satisfactory vacuum. In the meantime, there is no good reason for using an exhaust manifold so designed that it will retard the passage of the products of combustion, nor can it be shown that any good will come from delaying the passage

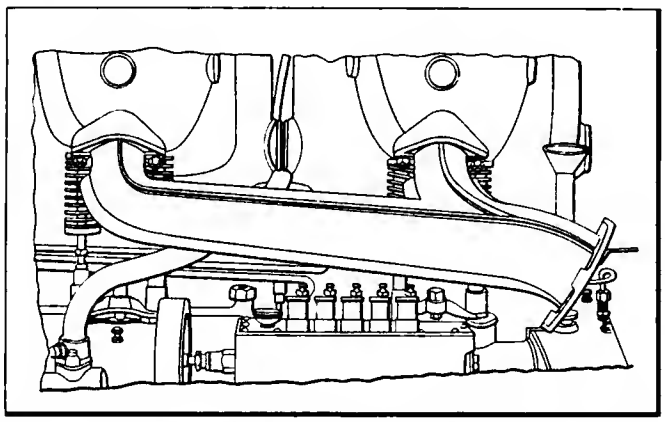

Fig. 52—Well designed exhaust manifold for a twin-cylinder motor of the four-cycle water-cooled type

of the exhaust to the atmosphere unless useful work is done.

In standard practice it is the idea to afford an easy passage for the exhaust, in a manner as shown in Fig. 51, which is an exhaust manifold as used on a two-cycle motor, with individual cylinders. As will be observed, this manifold is tapered down in such a way that the area is increasing as the needs, and it is also fashioned with easy bends at all points. Fig. 52 is a fine example of the same general plan, only in this case the manifold is placed on a motor of the twin-cylinder type; here, again, the area of the opening is increasing, so that there is no chance of "choking" the exhaust.

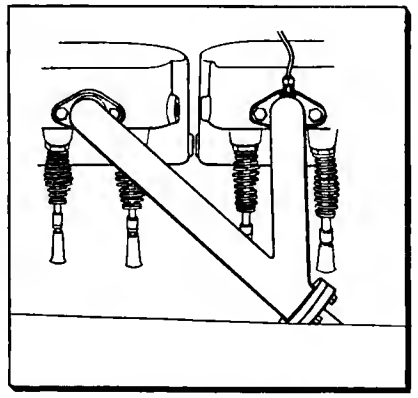

Fig. 54—Y-shaped exhaust manifold affording the advantage of saving bends in the exhaust pipe

In contrast with the designs already shown is the plan as depicted in Fig. 53, in conjunction with a two-cylinder motor (in this case) using flexible metallic tubing, the advantage of which lies in the perfectly uniform curves that can readily be made at the time of connecting up the exhaust; this same material is used with this motor on the intake as well. Against this material is the high first cost, which is compensated for by reduced cost of fitting, and finally there is the influence of the wrought interior to be given a fair measure of serious consideration. Whether or not the interior surface, as wrought as it is in flexible metallic tubing, will unduly retard the flow of the exhaust, is a matter that the author has not been able to determine, although he has used some of the tubing for this purpose, and found it to be very satisfactory. From the point of noise, it is believed that flexible metallic hose, so called, is quite free from this tendency, and it probably is true of it that it is a positive step in the direction of silent performance not counting its other advantages as ease in placing.

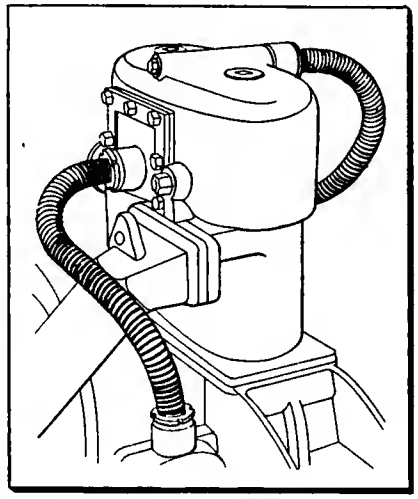

Fig. 53—Flexible metallic hose used for exhaust piping, affording a noiseless performance

Still another type of exhaust manifold is shown in Fig. 54, utilizing a "Y" form of branching, so contrived that the exhaust from the respective cylinders flows into the exhaust pipe proper at a point lower down than is usual in other forms, thus eliminating the bend that come in the exhaust pipe at a point near the motor. The same plan is illustrated in Fig. 55, on an air-cooled motor, and it possesses the advantage of tapping the heat away from the cylinders at the earliest possible moment.

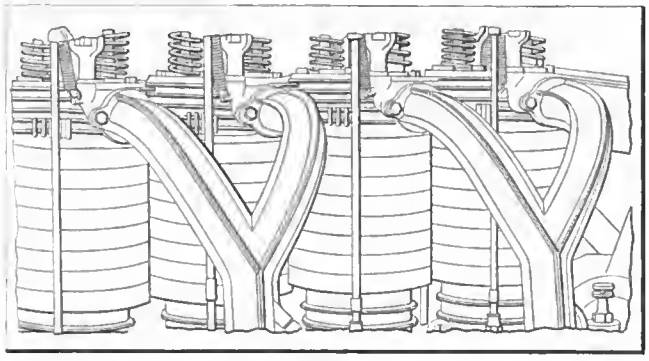

Fig. 55—Y-shaped exhaust manifold used on an air-cooled motor, employing two units and requiring abrupt ends at the pipe

Spark Plugs Should Be Well Clear of Manifolds—Frequently space is at a premium under the hood of a motor, and in the scramble to find room for everything, the parts are prone to interfere with each other. Fig. 56 shows the spark-plug rather too near the exhaust manifold, when it is placed on the exhaust side, which, in itself, is not an idea to be recommended. Even when the plugs are placed on the inlet side the same trouble is experienced betimes, and the disadvantages are by way of short-circuiting the high potential charge if the distance is infringing, and in any case it leaves but little room for the autoist to get at the plug with a wrench.

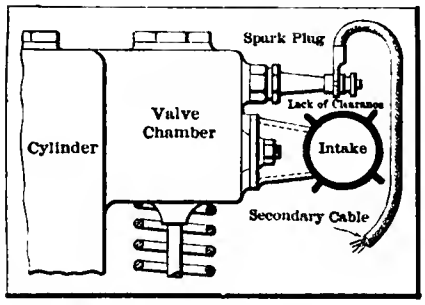

Fig. 56—Illustrating a wrong location of the spark-plug close to the manifold

If it is necessary to get at the spark-plugs with a wrench it is also desirable to be able to put on and remove the manifolds. If the studs are hid away under the manifold it becomes necessary to apply a chisel to them, and while it is possible to tighten the nuts by this method, it also has the disadvantage of destroying the heads in a very short while. Fig. 57 shows a manifold so designed that the heads of the holding bolts are accessible, and there is no good reason why this condition should not hold in all cases. Then, there is the question of the use of studs or bolts big enough to enable the manifold to be drawn up to make tight joints. The use of copper-faced asbestos gaskets is also well worth taking into account. As a rule, all these matters are well looked after, and there is no reason why they should not find universal application in automobile work.

Possibilities in Air-Cooled Work—Referring to Fig. 58, it will be to note that the exhaust is used to pull the cooling air into the jacket and over the heated cylinder surfaces; whether or not this plan is one that will find a wide use in future remains

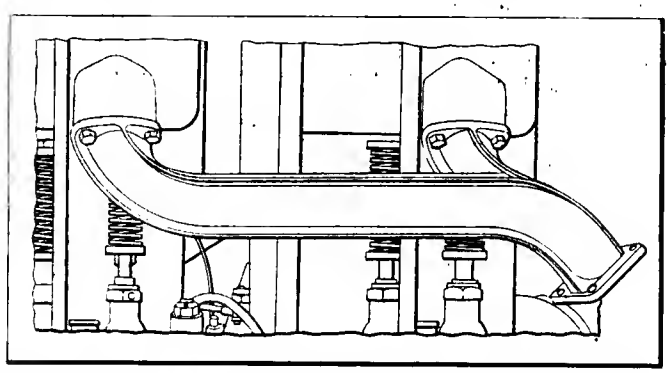

Fig. 57—Depicting a manifold in which the holding bolts are get-at-able, and of good practical size

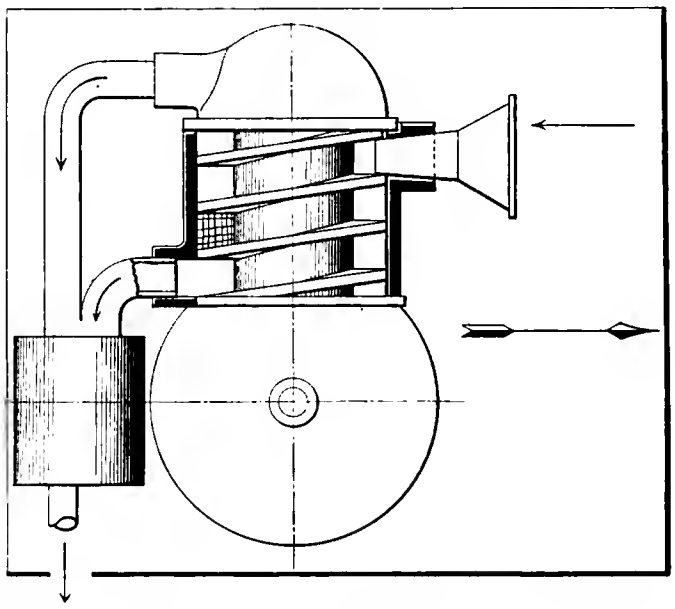

Fig. 58—The exhaust products of combustion are used to whisk the cooling air along

to be seen; yet, even so, it does look as if some use should be made of the energy that goes to waste in the exhaust. In this case the cooling air is passed around the surfaces of cylinders, and the exhaust products of combustion pass down to a point where the air and the exhaust join; the air is picked up by the exhaust and is whisked along with it and the amount of cooling

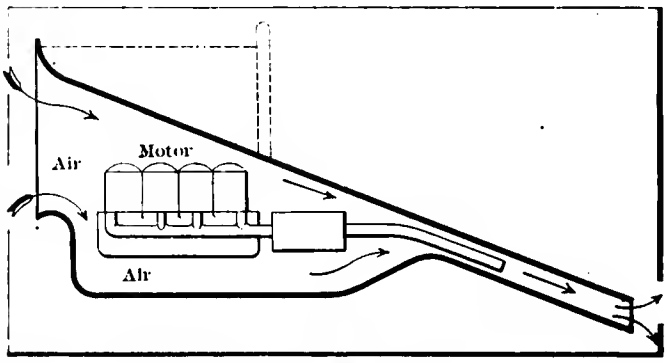

Fig. 59—Energy in the exhaust is used to sweep cooling air over all the motor surfaces

air that can be sucked in in this way should be adequate for the needs, which is in considerable contrast with Fig. 60.

Still another idea, differing from Fig. 58 more in detail than otherwise, is depicted in Fig. 59. In this case the exhaust goes to the muffler, which is located adjacent to the motor, and the cooling is drawn over the heated surfaces of the motor.

(To be continued.)

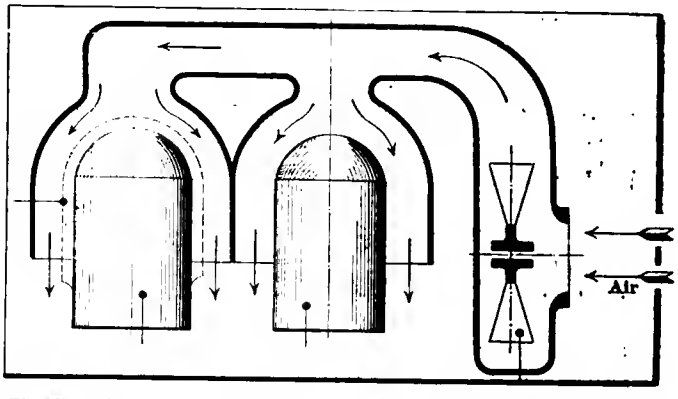

Fig. 60—Air-blast, through the use of a fan; may be adopted in conjunction with exhaust energy in the cooling process

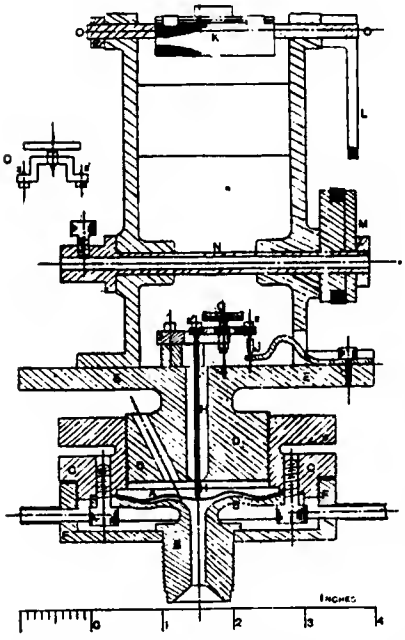
Thermal and Combustion Efficiency of a Motor *

By Prof. W. Watson, D.Sc.F.R.S.

IN a paper read recently Professor Watson gave a large number of tables and diagrams which were the results and deduction from a very thorough test conducted by him on an automobile engine. To engineers and designers much of this matter is of more than passing interest, so that part of it is given below, space not allowing a full transcript, valuable as the matter may be, and doubtless is. The motor on which the tests have been made is a four-cylinder Clement-Talbot having a bore of 85 millimeters and a stroke of 120 millimeters. In order to vary the compression the cylinders were raised on carefully machined packing pieces, the thickness of which was varied for the different tests. As, however, this alone would only permit of the compression being lowered below that for which the engine was designed, rounded aluminum caps were attached to the tops of the pistons. These caps were made a good fit on the pistons, and were so designed that no narrow crevices were left in which the gas of the compressed charge could remain unburnt. The caps were all of the same volume and weight, namely, volume 42.5 cubic centimeters (2.6 cubic inches), and weight 155 grams (5¼ ounces).



Indicator Section Showing Construction

The exhaust from the motor is led through a pipe 9 feet long and 2 inches in diameter to two expansion boxes placed in series, the volume of each box being 1 cubic foot. When the engine is working at full power and at 1,000 revolutions per minute, the mean pressure in the exhaust pipe immediately after it leaves the engine is about 1.8 pounds per square inch.

The carbureter is a single jet one with a float feed, and for the tests it was altered so that the extra air inlet is closed quite air-tight, and a needle was fitted so that by means of a micrometer screw the point could be moved up from below into the orifice of the jet and hence the effective area of the jet could be altered. In this way it was possible to obtain mixtures of any desired richness. The closing of the extra air inlet, which normally is opened by a piston on which the suction of the engine acts, causes all the air supply, even at high speeds, to be drawn through the choke tube surrounding the jet. Although this may assist in thoroughly breaking up the jet of petrol and so help in producing a homogeneous mixture, yet on the whole it was at a disadvantage, and the wire-drawing obtained as the speed increased is due to this cause. The inlet manifold was altered to a straight pipe with openings to the cylinders, the carbureter being connected at midpoint. The size of manifold was increased until all cylinders received an equal charge.

*Paper read before the Institute of Automobile Engineers, London, Eng., recently.

Two Spark Plugs Used Simultaneously—Ignition was by high-tension magneto with two spark plugs in each cylinder, one over the exhaust and the other over the inlet. At high speeds more power was obtained by using both plugs; thus at 1,100 r.p.m. the indicated horsepower was 18.4 with a single plug, while using the two plugs it rose to 20.8, a gain of 13 per cent. At a speed of 1,600 revolutions the effect was even more marked, the indicated horsepower being raised from 26.0 to 29.2 by the additional spark. This is equal to 12.3 per cent. The effect is due to the quicker ignition obtained with the two sparks, a matter of greater and greater importance as the speed gets higher and particularly so on racing motors.

The petrol supply was so arranged that the engine could either be fed from a reservoir or from a graduated glass vessel, the change from one to the other being made by means of a three-way cock. The temperature of the petrol in the measuring vessel was noted by means of a delicate thermometer, a matter of considerable importance since the density of petrol varies so rapidly with temperature. Each test extended over the time the engine consumed 400 cubic centimeters of petrol.

The cooling water was taken from a 20-gallon tank and circulated by means of a centrifugal pump driven by the engine, being then returned to the tank. An overflow pipe was provided to the tank and cold water was supplied at such a rate that the temperature of the water as it entered the engine was between 55 degrees C. and 65 degrees C. If the temperature was allowed to rise much above 65 degrees the water started to boil and the engine to show signs of preignition.

The engine was direct coupled to a shaft mounted on ball bearings, and on this shaft were mounted three sets of fan blades. The load was varied by altering the number and size of the blades. This arrangement for taking up the load is convenient in that the speed during a test remains very constant, for the load varies as the cube of the speed. It has, however, the very great disadvantage that the load cannot be altered while the engine is running and further small adjustments in load, such as would be required to keep the speed constant when the richness of the mixture is altered, cannot in practice conveniently be made. For this reason in the test described below the speed during any one set could not be kept quite constant. This is a distinct fault and renders the interpretation of the results, particularly with very weak mixtures, a matter of a little uncertainty. In future experiments along the same lines as these, I hope to obtain a dynamo to take up the load, in which case it will be easy to so adjust the load that the speed is the same for all tests.

Speed-Indicating Devices—The engine speed, that is, the number of revolutions, was measured by a Weston speed indicator, a well-known device, but a check on this was obtained

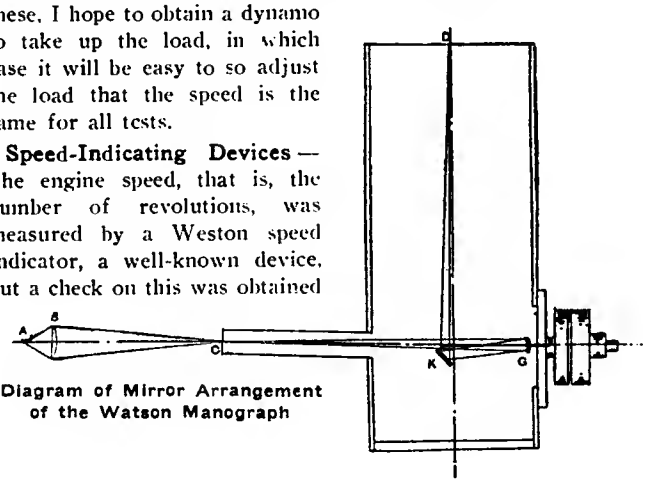


Diagram of Mirror Arrangement of the Watson Manograph

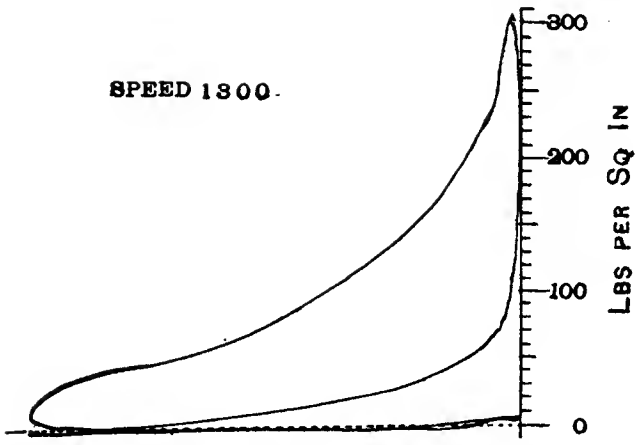


Typical Indicator Card Taken at a High Speed

by counting the revolutions per minute. The cards were taken by means of an indicator made by the writer and differing from both the Carpentier and Schultz instruments in the use of a corrugated diaphragm and two separate mirrors. The two mirrors are capable of rotation at right angles to one another, one being moved by the diaphragm and the other by the piston.

The internal construction is revealed by the first figure, while the second is a diagrammatic representation of the workings of the mirrors. The diaphragm A consists of a corrugated steel disc, .65 millimeter (.0256 inch) thick, the portion on which the piston acts being 44.5 millimeters (1.754 inches) diameter. As the success of the indicator depended upon these discs, they had to be made very carefully. The diaphragm is clamped between a steel cover B and a steel ring C. This ring is screwed to the gun-metal plug D, which is connected to the base plate E of the instrument by a narrow neck. In the first pattern of the instrument made, the diaphragm was clamped to the underside of the base plate E, but it was found that the readings obtained with an increasing pressure always differed slightly from those obtained with a decreasing pressure. After many weeks' work this effect was traced to a deformation of the base plate under the pressure and was entirely eliminated by the adoption of the present form. A box, F, screws on the back of the cover B and cold water is circulated in the space inclosed, serving to keep the temperature of the diaphragm at a very constant figure.

These indicators have been in use for more than a year and have been found to work satisfactorily and give a diagram 4 inches by 3.75 inches in which the pressure scale is uniform to within less than 1 per cent. This uniformity of the scale is of considerable importance when a large number of indicator diagrams have to be reduced, since owing to the shape of the diagram given by a petrol motor the author found it necessary to take at least 20 ordinates to obtain an accuracy of 1 per cent. A typical card taken at 1,300 r.p.m. is shown just as taken—that is, without retouching.

Use of Many Indicators Insures Accuracy—One indicator was used for each pair of cylinders, the connections being short steel tubes, which were water jacketed. Three series of tests were made with differing compression pressures, the change being effected by altering the thickness of the packing piece. In test A the piston occupied the high position, while in the B tests the highest position was 3 millimeters lower and in the C tests 8.6 millimeters lower than in the A tests.

The actual volume of the combustion space was measured by pouring in water, the cylinders being removed from the engine and inverted. A known volume of water was poured in and the level of the surface below the bottom flange of the cylinder was measured. Then allowing for the caps on the pistons, the volume which would have been present when the pistons were in place and in their highest position was calculated. Great difficulty was experienced in obtaining consistent results, it being very difficult to get rid of all air bubbles, and hence the results can hardly be depended upon to more than 1 or 2 per cent. The volume of the combustion space is very nearly the same in the case of each cylinder, as is shown by the following numbers:

Number of cylinder	1	2	3	4
Volume of combustion space (A tests)	183 cc.	184 cc.	180 cc.	188 cc.

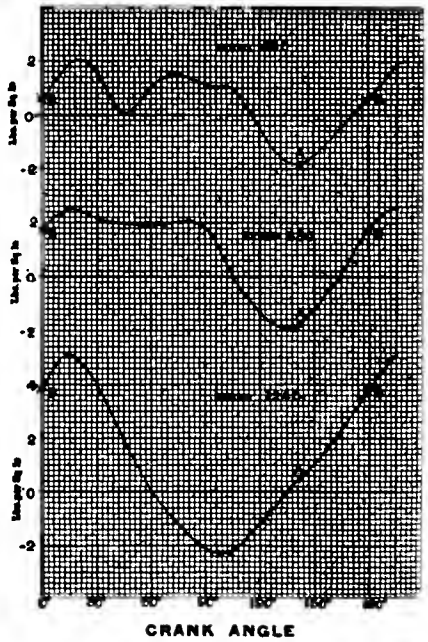
The equality in the volumes of the combustion spaces is also shown by the equality of the compression pressures as read off the indicator diagrams.

The average pressures for the four cylinders and in the three sets of tests are as follows:

Series.	A	B	C
Total volume at outer center	865 cc.	882 cc.	913 cc.
Volume at inner center	184 cc.	203 cc.	233 cc.
Compression ratio	4.71	4.35	3.92

Measurement of the Air Used by the Engine—The quantity of air taken by the engine at different speeds was measured by connecting the intake of the carbureter to a wooden box of 19 cubic feet capacity, the air being admitted to the box through a circular hole in a thin metal plate, and measuring the difference in pressure between the external air and the air in the box. The size of the hole was such that in every case the difference in pressure between the inside and outside was about equal to 1 inch of water. This pressure was measured by a King's gauge, the gauge being calibrated by comparisons with an oil manometer, a cathetometer microscrope being used to measure the length of the oil column. This gauge allowed the pressure to be read to within 0.002 inch of water. Leakage of air into the induction pipe, without passing through the measuring box, was reduced to a minimum by fitting stuffing boxes to the inlet valve stems and by packing the holes where the rod for moving the throttle passes through the induction pipe. To reduce the effects of the irregular aspiration of the engine a sheet of thin rubber was stretched over a hole 12 inches by 18 inches in the side of the box.

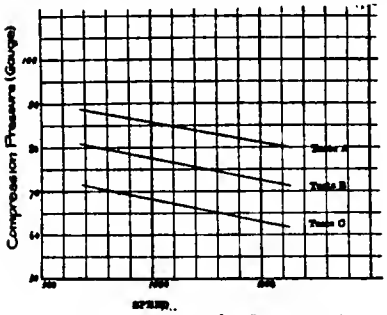
As the speed increases the quantity of air taken in decreases, this being worthy of investigation, as it will determine the size and proportion of the induction pipe and inlet valves of modern motors, which show a tendency toward higher speeds. The mean pressure in the inlet manifold was accurately measured, using a mercury manometer. The results when plotted show that the weight of air at any speed, say, 1,000 r.p.m., slopes down more than does the curve of mean pressure, which suggests the thought that the pressure of the air in the cylinder when the inlet valve closes falls more rapidly than does the mean pressure in the induction pipe. On the assumption that the latter is not equal to the mean another series of diagrams was made, these being shown. In them the point of inlet valve opening is at A, while the point at which the inlet closes is at B. The three diagrams show clearly what has never been shown before, namely, the drop in the inlet pipe pressure as soon as the inlet valve gets fairly open and also the continued rise in pressure when the valve has closed. The same effect is also noticed with the exhaust, the pipe pressure rising with the opening of the valve, the fall showing a very rapid drop due to gas inertia. The back pres-



Peculiar Curves in Exhaust Manifold

sure rises with increase in speed. At high speeds the induction stroke takes less time so the gases drawn in would have less time to acquire heat from the walls. At slow speed, on the other hand, liquid is without doubt drawn in which apparently reduces the total volume of cylinder charge.

Of interest to carbureter designers is the variation of the suction in the cycle. If the orifices through which the air is admitted to the carbureter are close to the jet the rise of pressure above atmospheric will not occur. If, however, as is often the case, air is drawn from near the exhaust pipe and is conveyed to the carbureter through a pipe of some length, then the rise of pressure due to inertia will be considerable. In the same way the manner in which the pressure in the exhaust pipe varies with the speed suggests that if it is desired to have a maximum power at a certain speed a little experimenting with exhaust pipes of different lengths will increase the power materially or give the desired result.



Illustrating Drop in Compression Pressure

If the thermal efficiency be plotted against the consumption of fuel in pounds per 1,000 r.p.m. it will be noticed that the efficiency increases as the mixture gets weaker up to very nearly the weakest mixture on which the engine will run regularly. In this connection it was observed that with mixtures containing between 17.5 and about 19 pounds of air to a pound of petrol, firing back into the carbureter was liable to occur, while with mixtures either richer or weaker this effect was not observed, the reason in one case being that the stronger mixtures burn so quickly that all flame is extinguished when the new charge enters, while in the case of the very weak mixtures the incoming charge is so weak that it will not inflame until it is compressed. The spark was in every case so adjusted that the maximum power was developed.

As a result of plotting all of these quantities it was found that at all speeds the efficiency is a maximum at an air to petrol ratio of about 17, while combustion would theoretically be complete at all ratios above 14.

High Efficiency Very Noticeable—One of the most noticeable things in the whole series of tests is the very high efficiency obtained, the maximum being .276. For one thing this establishes the fact that thermally the automobile engine is not only on a par with, but actually is superior to, all internal combustion engines excepting only the Diesel motor. The efficiencies were:

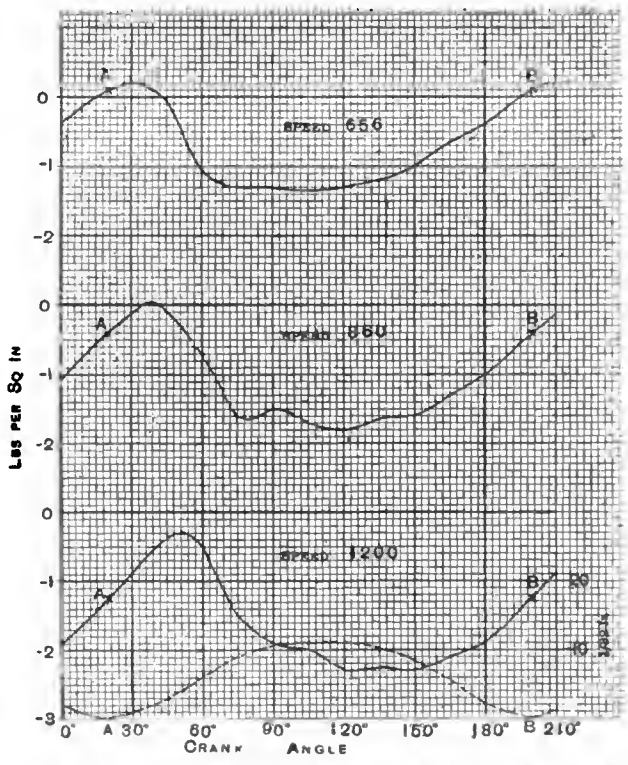
Test	Compression Ratio, Etc.	Air Standard Efficiency	Air/Petrol	Actual Efficiency	Relative Efficiency	Air/Petrol	Actual Efficiency	Relative Efficiency	Air/Petrol	Actual Efficiency	Relative Efficiency
A	4.71	.46	17	.28	.60	14	.25	.54	11	.20	.44
B	4.35	.44	17	.27	.61	14	.25	.56	11	.20	.44
C	3.92	.42	17	.26	.63	14	.24	.58	11	.19	.45

From the form of the combustion chamber in this engine the author had hardly expected to get so high an efficiency, for the surface exposed to the hot gases during the ignition (constant volume phase) is large compared to the volume. Thus a rough estimate of the surface area gives the values shown in the table below. That this ratio could be very materially reduced is shown by the numbers given for a combustion chamber having no valve pockets, a hemispherical top and a flat-topped piston. In such an engine the ratio of surface to volume of the combustion chamber would be only about half what it is in the actual engine. The reason the large surface exposed to the flame during the firing of the charge has not a more serious influence on the efficiency may be that the metal is coated with a layer of carbon; this layer being a bad conductor of heat, the surface actually exposed to the gas may be at a much higher temperature than would be the case with a clean metal surface, the other surface of the metal being water cooled. The presence of such a hot layer of badly conducting material would reduce the rate at which the hot gases lose heat to the walls of the combustion chamber. A similar argument does not apply to the portion of the cylinder traversed by the piston, since although there is a layer of oil, yet this layer is kept cool by the passage of the piston.

	Actual Engine.			Hemispherical Combustion Chamber.		
	A	B	C	A	B	C
Volume of combustion chamber.	184 cc.	203 cc.	233 cc.	184 cc.	203 cc.	233 cc.
Surface of combustion chamber..	370 cm²	378 cm²	393 cm²	181 cm²	190 cm²	205 cm²
Ratio of surface to volume	2.01	1.86	1.69	.99	.94	.88

Influence of Increased Compression—The result of increasing the compression does not have the effect that is generally supposed upon the mean effective pressure. By plotting the M.E.P. for the different mixtures three curves were obtained for the three tests, these being at three different compression pressures. In these curves it was shown that above a ratio of 14 any increase in the richness of the charge was not appreciable, while at that figure the M.E.P. only rises 2 pounds for a rise of 18 pounds compression—that is, at 68 pounds compression the M.E.P. was 83, while at 86 compression pressure the M.E.P. was but 85.

As the result of a close investigation into the composition of the exhaust gases and their relation to the power and speed, together with the theoretical composition of the exhaust, the author concludes that it is not safe to deduce the composition of the mixture supplied to a petrol engine from the results of the analysis of the gases made in the ordinary manner and on the supposition that the carbon all burns to CO_2, CO and CH_4, while the hydrogen is all present as water, CH_4 and free H. By means of the curves he does, however, think that the proportion of air to petrol can be deduced with sufficient accuracy for all practical purposes, and he hopes that the results will be of service to those who have to test carbureters and engines, as in many cases it is more convenient to analyze the exhaust gases than to measure the air and petrol.



Inlet Pipe Pressure Continues to Rise After Valve Closes

EFFECT OF SPEED ON TIRE PRESSURES

By Charles B. Hayward

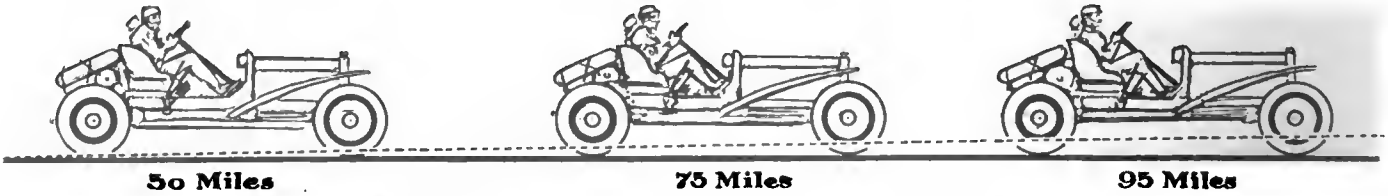
DESPITE S. F. Edge's carefully carried out experiments on Brooklands last year, designed to prove conclusively that the prevailing practice of inflating tires according to a schedule of pressures worked out by the tiremakers wasn't of exceptional value, no one appears to have seriously accepted his findings that half inflated tires were quite the thing, either for the welfare of the pneumatic or that of the car. At least, few autoists are seen driving their cars around on half-pumped tires, except those who would be doing it anyway: the fellow who doesn't know as yet and is just buying his experience, and the lazy chauffeur, who is helping speed the bosse's coin to the garagekeeper. Whether his own countrymen and fellow Britons take Selwyn F. at par value and regard his as an oracle in things motoring is a question that must be left to them to answer. He is with them, but not of them, for a more unbritish Britisher would be hard to find, at least where publicity methods are concerned. Somewhere back in his ancestry Edge must have had an American press agent, or a circus advance man, and S. F. is the result of an atavism. It seems difficult to explain his ability for keeping himself and his product so constantly in the limelight on any other ground. Whenever a "stunt" is pulled off in the autoing circles of the "Tight Little Isle," Edge is written large all over it, and the more unusual and extraordinary it is the more likely it is apt to be Edge. He crops up periodically in unexpected roles, and this tire business was one of them.

But, seriously, there is more in it than appears on the surface, and a little study of causes and effects throws considerable light on something that has been more or less puzzling to racing drivers ever since automobile speeds on the road got well above the mile a minute mark. Edge's experiments were designed to show that at high speeds and on a smooth surface it was possible to drive a car with partially deflated tires, not only without injuring the latter, but to their benefit, where the matter of endurance was concerned. Just how this worked out, or whether it actually did result that way outside of the published reports, is not the purpose of the present article to explain. As the result of his experiments Edge placed himself on record as advocating tire pressures considerably less than those recommended by the manufacturers and by automobile designers, on the ground that both easier riding and greater mileages would be obtainable. No experienced autoist has ever had any reason to doubt the former of these findings, but as already mentioned, few in this country, at least, appear to have given the latter the benefit of the doubt to the extent of trying it. Sustained high speed on a smooth and specially prepared surface, such as that of the Brooklands track, and the average touring speed over give-and-take roads present conditions that it is somewhat difficult to reconcile or draw any parallel between, so that in advocating the adoption of this expedient as a means of increasing tire mileages under everyday service conditions, Mr. Edge appears to have drawn somewhat more liberally on the press agent's license than is usual with him.

Whether this be the case or not, is beside the question. No attempt seems to have been made to explain why it was possible to drive a car at high speed with partially deflated tires, when all authorities so urgently recommend maintaining the pneumatics at a certain pressure, proportioned to the weight they are designed to carry, for ordinary speeds. For that matter, regardless of the speed, and the natural inference would appear to be that the faster the car was to be driven the more need there would be of properly inflating the tires. In fact, the adoption of a schedule of standard sizes of tires for certain weights and the pressures to which they should be inflated to properly carry such loads was the first great step in advance made by the tire industry, and regarded in the aggregate probably did more to lessen trouble with the pneumatic than any other single factor. So much for the need for pressure. The reason, or at least what may be accepted as such, for attempting to undermine what has already ripened into the well established custom of regarding no tire as safe that is not pumped to a good pressure has been pointed out.

Racing Drivers Seldom Aware of Punctures—It is a matter of common knowledge to the racing driver that a puncture is seldom, if ever, felt at the moment it occurs when driving at high speed on the straightaway. When the writer interviewed Hemery, winner of the 1905 Vanderbilt on the Long Island course, shortly after the race, he said he was not aware of the puncture that came so near costing him first place, as was the case with Robertson driving the Locomobile in last year's event, and did not discover it until the lateral weakness of the tire mare itself apparent upon rounding a curve, although the original accident must have taken place two or three miles before reaching that point. Doubtless other racing drivers can recall similar instances. The best road course ever laid out is far from being related to the proverbial billiard table, and the speeds of considerably better than a mile a minute—close to 90 miles an hour, in fact—that were attained on the straightaway stretches, magnify an almost invisible ridge or depression across the road into a thank-you-marm of the most virulent Pennsylvania type. What prevents a punctured tire from collapsing under this terrific pounding?

Centrifugal force appears to supply an answer. It is a well established principle that a body acting under the influence of centrifugal force tends to leave the source of that force at a tangent and to progress in a straight line. The average road supplies an unending series of tangents, along which the car flying at high speed tends to travel, and would follow were it not that the superior attraction of gravity makes it adhere to the actual contour of the road surface. The wheels, turning at high speed, supply sources of centrifugal force at four points and the terrific inertia of the swiftly moving ton of metal tends to overcome the attraction of gravity, and the machine bridges gaps which at lower speed would be followed in outline. This



50 Miles 75 Miles 95 Miles

Dotted Line Shows the Tangent to Surface of the Earth Which the Cars Tend to Follow at Various Rates of Speed

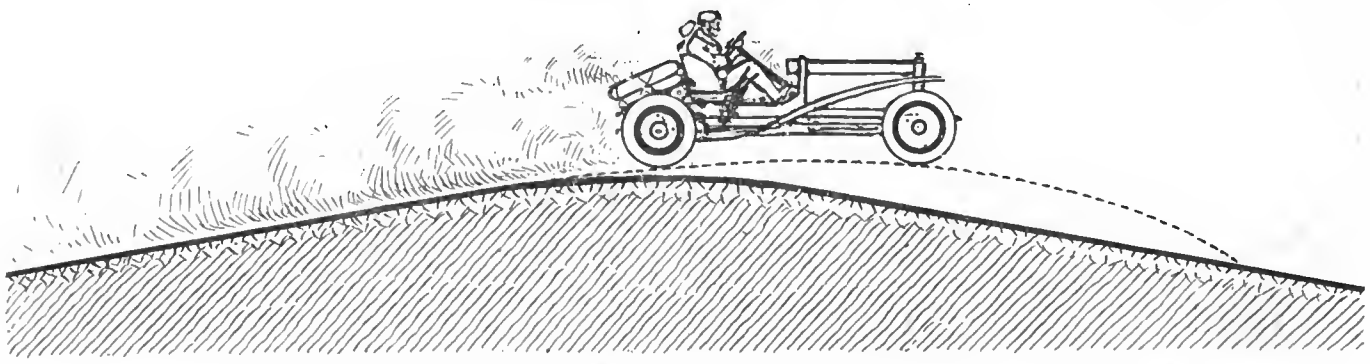
is what is expressed in the vernacular by "hitting the high spots."

As the Speed Increases—It will be evident that as the speed increases these forces do likewise. Whether in direct proportion or in far greater ratio is difficult to determine offhand. In other words, when the car travels faster and faster, as in being "let out" on a straight stretch, it tends to describe what an artillerist would term a rising trajectory. The only thing that prevents this being visible to the unaided eye on an ordinary piece of road is the fact that gravity is still strong enough to keep the car on the ground, and fortunately, speeds have not yet attained a point where this universal force is overcome altogether. Otherwise, some raving drivers might have anticipated the achievements of the Wright brothers unintentionally long before they were ready to give their secret to the world. But where conditions are unusually favorable, such as those supplied by the numerous "dip-of-death" bridges spanning the roads that intersect the Long Island Motor Parkway, the effect is no longer invisible, and due to their terrific inertia the racing cars actually do describe a rising trajectory when leaving the upgrade face of the stretches leading to these bridges. This was strikingly shown by the photograph of Robertson's Locomobile, with all four wheels above the ground, that was taken during the last Vanderbilt race, and which is reproduced herewith.

It has already been pointed out that as the inertia and centrifugal force developed by the moving car increase, the attraction of gravity is overcome to a constantly greater extent. This is equivalent to stating that at 70 miles an hour a racing car weighs far less than when running more slowly, or when standing idle. Actually, there has been no change to bring such a magic transformation about, otherwise entrants might be desirous of having their machines weighed as they passed over scales located in the center of smooth five-mile straightaway, where they could do their best. But in so far as the weight bearing on the tires is concerned, it is true. Therein lies the explanation of the possibility of running at high speeds on a punctured tire without the driver or his mechanic being aware of the fact that one of the rubbers has suffered. In a four-inch pneumatic, for instance, a pressure of approximately 80 pounds to the square inch is requisite to support the load represented by a car designed to carry tire equipment of that size, without permitting the walls of the shoe to bend unduly—a privilege that comes high. Taking the weight of the car at 2,200 pounds and that of the driver and his mechanic at an additional 300, it will be evident that when standing idle each wheel is bearing 625 pounds weight, distributed over a relatively small surface—that of the point of contact with the road—the external pressure per square inch is very high.

Under Ordinary and High Speed Conditions—When a tire punctures under ordinary conditions, the sum of these pressures is combined to force the air out through the opening thus made. But a similar accident at high speed is not attended by immediate results of the same nature. To a very great degree—dependent upon the rate of speed, of course—the tire is relieved of the tremendous external pressure it would otherwise have to bear, and while its internal pressure is more than sufficient to insure the hasty exit of the air, the tire does not collapse for the reason just given. In other words, the car's speed makes it self-supporting to such an extent that on straight stretches it continues to travel upon a pressureless tire almost as if nothing had occurred, and Mr. Edge's experiments demonstrated that this was true in such measure that it was possible to drive a car at high speed on four tires inflated to far below their normal pressure. So much for that part of the theory. It is a valueless one, so far as any real benefit to be derived from it is concerned.

However, an attempt has been made to show graphically just how it works out. This will be seen in the accompanying sketches. Taking the stretch of level road as representing the circumference of a circle of infinite radius, the dotted line is intended to depict the lifting effect of the combined forces generated by the speed of the car, as well as the tangent that it would tend to follow were its flight sufficiently fast to entirely nullify the attraction of gravity. Naturally, the degree to which this holds true must be assumed, though it seems quite probable that at from 75 to 95 miles per hour, the external pressure, or actual weight carried by the tires, is so far reduced as to become an almost negligible factor. No other deduction seems possible in view of the results of the experiments mentioned, when regarded in the light of the experience of racing drivers to the same effect. The rate of speed at which this assumes sufficient importance is also a matter for conjecture, though it seems quite probable that the effect in question would be almost wholly lacking at less than 50 miles an hour. The rising trajectory has been plotted with these rates of speed as checking points.



Reproduction of Trajectory Described by Robertson's Locomobile in the Last Vanderbilt Race

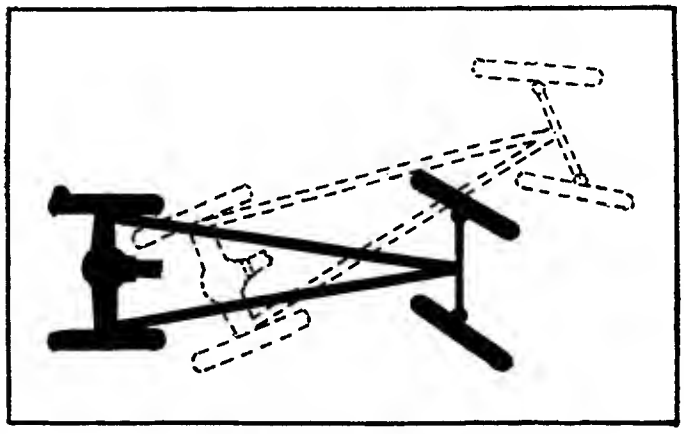
The second sketch is intended to outline the trajectory followed by a racing machine crossing one of the Long Island Motor Parkway bridges at high speed, and is naturally exaggerated for the purposes of illustrating, though in reality it is not overdrawn to any great degree. How true this is may be judged of from the photograph depicting the actual occurrence. It will be evident from a study of the sketch that the conditions are usually favorable for obtaining this effect owing to the abrupt end of the grade and the corresponding drop on the other side, but a little study will show that this is but a reproduction of usual road conditions on a vastly enlarged scale, and the bodily departure of the machine from the ground is but a longer flight of the same nature that a car traveling at a great velocity is continually taking when it "only hits the high spots." The ease with which a car steers at high speed may also be regarded as evidence of the decreased pressure on the wheels of the weight of the car.

It may be thought at first sight that a flight such as that which the camera caught Robertson's Locomobile in the act of making in the last Vanderbilt, could only be possible under the unusually favorable conditions of road contour that there existed. But that this is the usual, rather than an extraordinary effect, to be expected under conditions at all similar, was shown by a photograph of Haupt's six-cylinder Chadwick leaving the ground at the top of Giant's Despair in the hill-climb a year ago. All four wheels of the car were in the air, but the effect was naturally not quite as striking, as a level stretch followed the brow of the hill and the speed attainable up such a grade could not be compared with that made on a cement straightaway.

Aids in the Driving of a Car — Part 4.

By D. R. Hobart

THREE things are to be remembered with regard to side slipping and skidding. First, either the front or rear wheels are liable to slip sideways if the driver attempts to alter the direction of travel suddenly on a greasy road. Second, rear or driving wheels when driving are more likely to lose their grip on the road than those which are rolling freely. Lastly, a spinning wheel or one which is locked loses its individual direction of travel and becomes simply a point of contact on the road. From this it will be seen that side slip is usually experienced with the rear wheels and depends on the application of the brakes, and the care in driving and that it need not necessarily result from taking a turn too rapidly or too sharply. This can be shown by driving a car along a greasy road and applying the brakes with sufficient force to lock the rear wheels. The car



Illustrating a Front Wheel Slip

will immediately tend to turn end-for-end upon the road and even if the road is not greasy a sort of side slipping is set up, which can be corrected by the steering gear, in causing the front of the car to move sideways in unison with or to a greater extent than the rear wheels. If the rear tires cannot obtain any grip on the road, as they are being dragged over its surface the rear of the car is apt to swing around too quickly for the driver to check such a tendency in the brief time available. Side slips of this character can only be checked by either releasing the brakes and thus freeing the wheels or by causing the front wheels to keep the car parallel with the road as soon as the first signs of slip become apparent, since once the rear of the car has swung around to any extent the driver is powerless to bring it in position again by the manipulation of the steering gear. The wheels need not be actually locked in order to bring this about; all that is needed is for them to lose their grip on the road and this occurs when they revolve at a slower peripheral speed than that of the car or when driven at a higher speed than that at which the car is moving. Skidding usually occurs to cars which have front wheel brakes or to other cars when the driver is successfully continuing to counteract the accompanying tendencies to side slip.

Front-Wheel Slips Infrequently Encountered.—Front-wheel slips due to deviation of the car from a straight course or to excessive camber of the road are not often encountered even though the front wheels are usually fitted with smoother tires than the rear wheels. Such slips when they do occur are most unpleasant, as the autoist has no control whatsoever over the car while they last. Generally speaking, a front-wheel slip occurs when a fairly sharp turn is being made on a road covered with greasy mud or when the road falls away steeply to the drains at the side. Judicious application of the brakes will often have the effect of straightening up the car as well as of retarding it, if there is sufficient room at the side of the road to which the slip is occurring, but the best way to check the slip is to bring the front wheels well around in the direction that is desired to be taken. By doing this, the front wheels tend to reduce the speed of the car and to squeeze the mud away from in front of them. The autoist must be on the alert to straighten them up immediately they obtain a hold on the road, as otherwise the car will move toward the other side of the road with startling rapidity. The sketch shows a typical front-wheel slip.

Slips Due to Acceleration or Retardation of the Wheels—Rear-wheel slips due to acceleration or retardation of those wheels should be checked similarly to slips resulting from sudden alteration of the direction of travel. The differential gear on the car is likely to aggravate slips of this nature as the wheel which has the least adhesion to the road, by spinning forward at double speed, can relieve the whole of the drive from the other wheel and the car will slew around on the stationary wheel as a pivot. A brake on the transmission between the motor and the differential gear will cause the wheel that grips the least to spin backwards under the driving influence of the other wheel, and a similar slewing action is set up. The autoist should remember that both rear wheels must be on firm ground before the brakes or accelerator can be operated to overcome the slip. Imperfectly balanced hub brakes are a fruitful source of side slip of this nature as one wheel is called on to do the greater part of the braking and one locked wheel is pretty sure to throw the rear part of the car around sideways.

Slips on Ascending and Descending Hills—Of frequent occurrence in general driving is the descent of steep and slippery hills. Obviously, the brakes must be used in order to keep the car under control, but the autoist often finds that their application causes the rear of the car to swing right around, particularly if one hub-brake has a better grip than the other. With smooth tires, that is, tires without studded treads or unequipped with chains, the situation is hazardous despite all anything the autoist may do, but in all cases such hills should be approached at a walking pace and the car prevented from increasing its speed by judicious use of the brakes the whole way down. A typical slip of this type is shown in the sketch, the dotted lines indicating the position often assumed by the car at the completion of the slip. Equally awkward is the ascent of a hill thickly coated with mud or ice. In such case, once the wheels commence slipping the car may tend to spin in a circle and to slip backwards while so doing to the bottom of the hill. If the hill is extraordinarily steep and greasy, several circles may be described if the car is small or has excessive clearance and the autoist will not have the slightest control over the car during the evolutions. In climbing ordinary hills that are greasy, a moderate speed should be maintained from bottom to top, avoiding any sudden acceleration of the road wheels, and momentarily easing off the drive to enable them to regain their hold at the first signs of excessive spinning. The ability to drive at a constant speed is invaluable to the autoist in cases like this. Where ascents or descents are hazardous, rope wound around the tire and felloe

is of the greatest assistance. Gunny sacking, lap robes or even newspapers laid on the road are excellent when the tires are unable to obtain any adhesion.

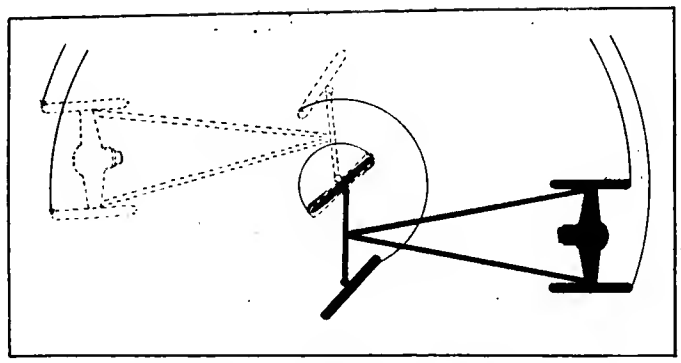
Typical Instance of Skidding—Skidding occasionally occurs when the autoist is endeavoring to bring the car to a stop within a limited space. On wet or slippery and even on dry roads at times it is difficult to pull up quickly if another vehicle has suddenly stopped a short distance ahead of the car. Setting the brakes introduces side slip at the rear, and while this tendency can be checked by means of the steering gear the forward skid will continue in many cases. The fault is, of course, on the part of the autoist in having approached the other vehicle at too great a speed consistent with the state of the road and with regard to the efficiency of his brakes. To obtain the maximum retarding effect under such circumstances, the brakes should be applied and released alternately with a quick vibratory motion of the foot, a powerful braking influence being thus brought to bear on the wheels, and the intermittent periods when they are free to roll enabling them to maintain their grip on the road.

Experience Teaches Suitability of Tires to Road Surfaces—As the autoist encounters various kinds of roads when driving he soon learns to know those that are slippery when wet or muddy and how any road should be negotiated with either smooth or non-skid tires. Where the road is greasy, smooth tires can obtain but little hold, whereas studded or non-skid tires are usually capable of reaching bottom through the coating or film and gripping the road. On the other hand, new non-skids will slip badly on Belgian block or other hard-surfaced roads while smooth tires will adhere nicely thereto. The same distinction may be drawn between smooth and studded or non-skid tires as between rubber-soled shoes and heavily-nailed boots in regard to certainty of locomotion.

Slow Traveling the Best Remedy—Whenever the road is inclined to be treacherous, slow traveling is the best remedy against side slips and skids. The autoist should avoid using the brakes at all if possible and this he can do only by concentrating his attention on the road at a much greater distance ahead, as regards speed, than is his usual custom. If a turn is to be made, or if the brakes have to be used he should take advantage of dry spots or any camber favorable to his purpose, as it is frequently possible to choose to some extent the exact course that is taken. For example, if a pull up or considerable reduction of speed will be necessary within the next few minutes, a lookout should be kept for less slippery spots which may be of service or at the least choose a portion of the road where the conditions are no worse than that over which the car is progressing at the time. The same thing should be done if a turn of any nature has to be made under the same circumstances. The risks of side slip can thus be reduced if not altogether eliminated. Various other methods of preventing side slips are used by autoists, depending on the circumstances, and these are the result of experience and in some cases suited only to certain cars.

Stopping for Any Cause—When stopping for any cause the autoist should bring the car over to one side of the road so that it will be out of the way of other traffic. In doing this a position should be taken up so that when the car is started again there will be no difficulty in getting under weigh. In bringing the car to the roadside, as in the sketch at A, the autoist not only allows others the use of the road but protects himself from being run into or hindered while making repairs, etc. On the other hand, autoists who are otherwise considerate sometimes remain in or near the center of the road as at B, if the stop is an involuntary one, and commence repairs, hindering others from passing and running the risk of being hit by other cars. The excuse usually given in such cases is that they did not know that the road was much traveled over, and thought that the center of the road was as good a place as any to stop.

Plenty of Space Should Be Allowed When Pulling Up—One of the mistakes committed by inexperienced, and indeed, quite a number of experienced autoists is in not allowing sufficient space on all sides when pulling up. It is a common occurrence to see the driver of a car backing and going ahead inches

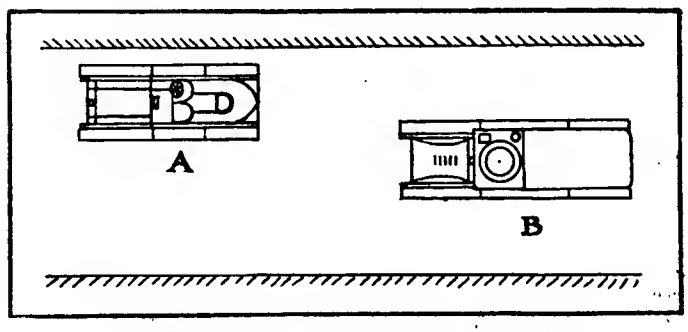


Typical Slip When Descending a Slippery Hill.

at a time in the endeavor to get clear of the curb which he has approached too closely. Occasionally also an autoist is seen who has driven up too closely to another car and left no room to get at the starting crank after the car has been pulled up and the motor stopped. The remedy is obvious; allow plenty of room in all cases. The car can be brought up to the curb and stopped with the front wheels turned slightly to the left, and the off rear wheel about a foot away from it. From this position there will be no difficulty in starting off when it is desired to do so.

Forethought When Making Repairs on the Road—It is obvious from what has been said in regard to stopping, that corners and narrow roads are not the safest places to conduct repairs in. Neither should a tonneau door be allowed to remain open nor tools be scattered over the road. A good habit to follow with regard to tools is to place those needed for the particular work on the running board, and as each has been used to return it thereto. In all cases the autoist should place the change gear lever in the neutral position and set the hand brake before leaving the seat. Accidents caused by the car running down the driver when cranking will thus be prevented. If the car is to be pulled up on a comparatively steep hill, it would be well to bring the front wheels around sharply and allow the off wheel to rest against the curb or bank at the side of the road.

Coast as Often as Possible—Coasting should be indulged in whenever the nature of the country and the amount of traffic on the road will allow it to be done with safety. Not only does coasting tend to economy in fuel but it allows the motor to rest, particularly if the latter has been working hard in climbing hills or running over heavy roads. When about to coast the motor should be declutched, the gear lever put in the neutral position and the motor slowed down to its slowest speed. If the hill is a long one, the motor may be stopped entirely, thus stopping the consumption of fuel and the wear and tear on the motor and allowing the latter to cool off. With sliding gears, the high-speed position can be used instead of the neutral whether the motor is running during the coast or not. At the top of a long hill the switch may be thrown off after declutching, but before the end of the hill is attained the ignition should be switched on and the clutch let in gently, starting the motor by the momentum of the vehicle. The autoist should always employ the highest gear when starting in this manner as the stresses imposed on the mechanism through using a lower gear would be too severe, and might result in a bad breakdown.



Proper and Improper Positions When Pulling Up

SOME SELECTED AUTOMOBILE PATENTS

Issue of May 18, 1909

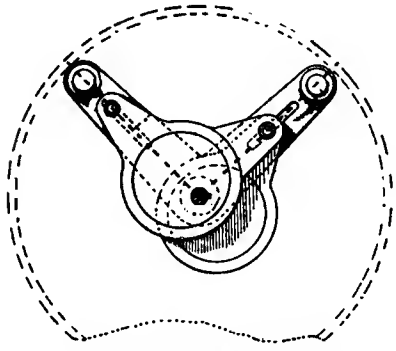
921,897. Automatic Cut-Off for Gas. Ludwig Schmidt and Herbert Schmidt, Kaiserswerth, Germany. Filed March 6, 1909.

921,933. Engine-Starter. Daniel C. Wilgus, Los Angeles, Cal. Filed March 29, 1907.

921,936. Antiskidding Device for Wheels. Robert M. Winsch, Lansdale, Pa. Filed Feb. 15, 1909.

921,963. Automobile Vehicle. Leonard H. Dyer, Washington, D. C. Filed Feb. 3, 1900.

921,978. Compensating Gear. Edwin J. Gould, Boulder, Col. Filed April 13, 1908.



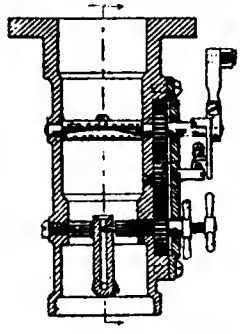
Gould Differential Substitute

The Gould substitute for a differential, shown herewith, was the subject of a spirited discussion in the technical press about a year ago, or, to be exact, as soon as Gould published an account of his device, which he did as soon as he had applied for the patent. The discussion developed the principles of the gear, which were thrashed out very thoroughly. As to its actual use, only time can show what it will do. The idea is a move in the right direction, for it replaces a complicated and expensive piece of mechanism, with a simple, cheap, and, as the inventor claims, a superior device.

921,994. Variable-Speed and Reversible Gear. George P. Innes and Thomas Con Allen, Sydney, New South Wales, Australia. Filed May 18, 1908.

922,145. Carbureter. Albert Howarth, Providence, R. I. Filed May 31, 1907.

Howarth, too, is working for simplification, his carbureter being without the usual float chamber, and the spraying nozzle being much



Howarth Connects Throttle and Spray

simpler than is the ordinary case. One new idea which he has worked in is the connection of the throttle with the nozzle by means of gears so that they work together.

922,009. Gasoline-Engine. Gustavus H. Marquardt, Cassville, Mo. Filed Aug. 27, 1908.

922,044. Steering Mechanism for Vehicles. Albert F. Rockwell, Bristol, Conn. Filed Nov. 3, 1905.

922,057. Automatic Swivel-Lamp for Automobiles. Julius O. Spang, Haileybury, Ontario, Canada. Filed Dec. 17, 1908.

922,278. Automobile-Wheel. Ole A. Hamre, Arriba, Col. Filed July 26, 1907.

922,308. Rear Axle for Automobiles. Frederick C. Miller, Cincinnati, Ohio. Filed July 16, 1908.

922,402. Demountable Rim-Tire. Alexander Dow, New York, N. Y. Filed Dec. 30, 1908.

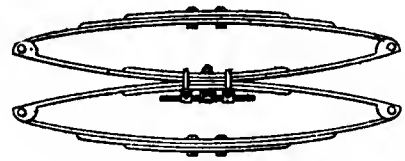
922,403. Locking Device for Demountable Tire-Rims. Alexander Dow, New York, N. Y. Filed Jan. 29, 1909.

922,404. Demountable Tire-Rim. Alexander Dow, New York, N. Y. Filed Jan. 29, 1909.

Issue of May 25, 1909

922,454. Vehicle Spring. Lewis C. Burnet, Newark, N. J. Filed Sept. 11, 1908.

Burnet's compound spring is well known to readers of this paper, particularly those who read the advertisement pages. In this, as the patent drawing shows, there are two full elliptic type springs superposed, one being directly above the other. The upper one is fastened to the automobile frame in the ordinary manner, while the lower follows usual practice in its attachment to the axle.



Burnet's Compound Spring

922,489. Motive Power for Automobiles.—Edward S. Lea, Trenton, N. J. Filed Nov. 9, 1907.

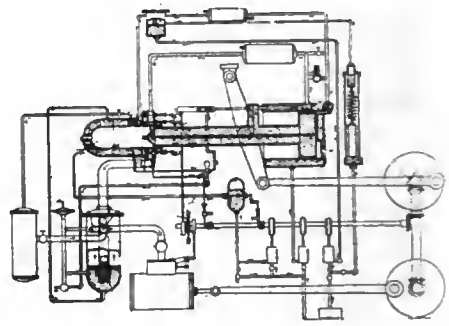
922,509. Compound Explosive Engine. Sidney A. Reeve, Worcester, Mass. Filed June 18, 1906.

There have been a number of attempts to produce a slow burning rather than an explosive engine, along the lines of Brayton,

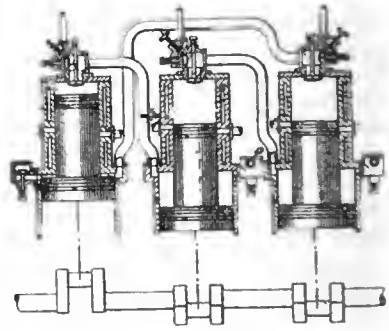


Reeve Compound Explosive Engine

the great American pioneer. Of those interested in the subject, Professor Reeve is prominent, and the patent specification and drawing show the outlines of his proposed system. In the drawing too many parts are perhaps included, so that the main issue is rather beclouded, but the idea is there, at last put into working form. The Brayton, and consequently the Reeve, come in what is called the first class. This is the type of gas engine igniting at constant volume but without previous compression, and represents, in principle at least, the simplest and most apparent method of obtaining power from gas.

922,911. Internal-Combustion Engine.—Thomas D. Kelly, Essex, England. Filed Nov. 8, 1907.

In the van of the parts which are now receiving the attention of inventors, engineers



Differential Piston Two-Cycle Engine

and designers, is found the engine, and prominent in these are the attempts to improve over the two-cycle form. Kelly has used the differential piston type, and uses the three-cylinder form. The first cylinder, at the lower diameter compresses the charge for the upper or explosive part of the piston in cylinder number two, the lower part of which performs a like function for number three. The latter, in turn, compresses the gaseous mixture for the first. The most apparent objection is the extremely large compression space necessary.

Letters Interesting and Instructive

FRICTION DRIVING

Editor THE AUTOMOBILE:

[1,905]—Please inform me through the columns of your paper if a friction-driven car is considered just as strong a car going up the hills as a direct-drive rear axle. Would also ask you to furnish the names of manufacturers who can supply parts for this type car, that is, the friction drives. W. H. S.
New York, N. Y.

It is generally considered that the efficiency of chains is superior to that of bevel gears, so that chain-driving presents advantages over the shaft drive. Yet the majority of cars are shaft driven. From this it is evident that other considerations than the mechanical efficiency govern the use of any device. So it is with the friction drive, good as it may be, the American people did not take to it, and as a result there are not many cars built using this form of drive. In some ways it is logical, for do not all cars ultimately drive by means of the frictional contact between the wheels and the road surface? Also, in the case in which a clutch is used, is not this a matter of frictional surface transmitting power.

Yet, in the face of all this reason, the form is not popular and the number of cars produced is small.

As to the firms making parts for such cars, at the present moment but one is recalled, the High Wheel Auto Parts Company, Muncie, Ind.

FRONT DRIVE ADVANTAGES

Editor THE AUTOMOBILE:

[1,906]—Will you please give me some idea of the reasons for the use of the front wheels for driving a car? Does not this complicate the mechanism of the car as a whole? Could you give a list of cars which are now made with this form of drive and the addresses of their makers? G. K. O'HARA.
Chillicothe, O.

There are a number of reasons advanced for this construction, chief among which are: absence of side slip usually spoken of as skidding; shorter turning radius, due to increased angle of steering lock permitted by this form of construction; pulling the car rather than pushing it is more rational and is said to be more efficient; concentration of parts in one position, and that an accessible one, allows of minimizing trouble, and thus locating it more easily; the concentrated construction allows of a number of minor economies which, on a large scale, might develop the whole into a lower-priced form.

Some of these reasons for the front drive are worthy of more than passing mention, thus the entire absence of skidding, if it could be proven, would more than offset the mechanical complications incident to driving and steering through the same wheels. The exact proportion of automobile accidents due to side slipping probably will never be known, but if it were known it would be very large. In the crowded streets of the larger cities the problem of turning around is a large one, for narrow streets will not allow of several successive backing up operations necessary in the turning of a large car. Then, too, the backing-up process requires a reverse speed, which under favorable conditions could be eliminated with a very short turning radius. This latter simplification would reduce cost, weight, make the control simpler and easier to understand, and through the medium of lesser weight would reduce operating expense.

The pull versus push proposition is one of theory, and the efficiency, or lack of it, innate in either form has never been proven, at least conclusively. As a matter of pure reasoning, however, it sounds well.

The last mentioned reason carries the most weight, for incident to the concentration of parts into a small compass is the possibility of uniting them into a single unit, which has been given the name of a "fore-carriage." This would be removable as a unit, and therefore would allow of its instant removal and the equally quick substitution of another. In any public service passenger or goods carrying business this is a reason that would outweigh any which might be brought out against the cars, for this form of construction allows keeping the vehicles in service and therefore earning money for the largest possible part of the time.

It is not possible to give a complete list of the makers of front drive cars, as this would mean too much space, and no such list has ever been compiled so is not at hand. Three makers who are known to be building front drive cars are: Christie, New York City, a description of whose cab is given in this issue; Haydock Automobile Company, St. Louis, Mo., and the Four Drive Traction Company, Mankato, Minn., the latter firm's product being both front and rear driven—that is, what is called four-wheel drive.

FROM NEW YORK TO DENVER

Editor THE AUTOMOBILE:

[1,907]—I am contemplating taking a trip from Buffalo to Denver this summer. Will you please, through your "Letters Interesting and Instructive," tell me the best route. This can best be done, I think, by naming the towns and cities through which we should pass. OTTOMAR O'DONNELL.
Fishkill-on-Hudson, N. Y.

Section 4 of the official A. A. A. Blue Book, which will appear early in July, will give the roads from Buffalo to Omaha, Neb., passing Cleveland, Toledo, South Bend, Chicago, Clinton, Ia., and Omaha, Neb. Beyond that point the road would take in Grand Island, Neb., Julesburg, Fort Morgan and Denver.

STARTING ON MAGNETO

Editor THE AUTOMOBILE:

[1,908]—Will you kindly state, to settle an argument, whether it is possible to start an engine on the magneto, not once nor twice, but regularly every time?
Hoboken, N. J. BEN DAY.

It is not only possible, but very probable, since as a matter of fact a number of the good small French cars have no other source of ignition, and an increasing number of our best American cars are being fitted up in this manner. Nearly all of the magneto manufacturers are marketing some device to aid in spinning the armature or otherwise helping to produce a spark the first time, no matter how often it is tried. Very recently, in these columns, a device called a switchstarter was described, the function of which was to send a sudden current through the primary windings as soon as the switch was touched. This actuated a contact breaker, which sent current from a special accumulator through the primary armature circuit.

Another device was in the nature of a clutch, which was operated to free the magneto shaft when it was desired to start the engine. This being free, other forms of mechanism whirled the armature around very rapidly several times, invariably producing the desired spark. The clutch automatically slid back into place when the motor had been started and was running normally. Other and equally successful devices have been brought out for this purpose, their action being so certain that one is safe in saying as above that it is perfectly possible to start on the magneto not once or twice, but every time.

DUAL IGNITION QUERY

Editor THE AUTOMOBILE:

[1,909]—Will you please give me some advice on the subject of dual ignition? I am about to buy a car and am in doubt between two makes, one with dual ignition, and the other with magneto ignition only. Which would you advise and why?
Poughkeepsie, N. Y. T. H. LLOYD.

It is a fact that the progress in igniting apparatus, in magnetos particularly, during the past year has been remarkable, and as sold to-day they are very efficient and reliable. Starting has always been the magneto "bugaboo," but the up-to-date magneto has overcome this and stands on a par with any other obtainable source of ignition in this respect.

This being the fact, why would you wish to complicate matters with an additional system which you will never use unless you have an accident to the major system? If the latter is not reliable, why put it on at all? If it is reliable, why not depend upon it and dispense with extra weight, cost, mechanical and electrical complications?

It is urged against the use of a single

system, that it is similar to putting all the eggs in one basket, so that any accident puts the car *hors de combat*. But if a second system is provided, one simply switches over to it and comes home as if nothing had happened, the major ignition being fixed up at leisure. It is reasonable to assume, however, that a minor system carried for hundreds or thousands of miles preparatory for the accident that may happen may itself get out of order, so that when called upon it cannot respond. In this case the cost, weight, and complication would go for naught.

The experience of millions of miles running with the cars of a public service corporation abroad proves that with two complete and distinct ignition systems the drivers are careless with both on the assumption that if one gets out of order the other can be used. With single ignition it is necessary to take care of the system, for it is the *only* source of current. The added care necessary in the latter case resulted in a very large saving upon the universal adoption of a single source of current, and it just happens that this was the form which has been argued for above, namely, the magneto system.

Without knowing the two cars which you have in mind, or without actually advising you which one to purchase, it would seem best for the beginner to begin on a car with single ignition, whichever form that may be, although the argument, as given above, has seemed to favor the mechanical current generator.

PERCENTAGE OF GRADES

Editor THE AUTOMOBILE:

[1,910]—Won't your figures in regard to the grades on the Pacific Coast, referred to on page 833 of the May 20 issue of "The Automobile" bear revision?

An average grade of 13 per cent. for a distance of 160 miles would certainly be "some Alps." E. C. HILLIARD.

Hartford, Conn.

Our correspondent is correct in his statement that this would be "some Alps." The mistake made by a contributor, and not checked up by us, simply goes to prove that the oft-reiterated statement that per cent. and actual rise of grades are not generally understood contains more truth than poetry or fiction.

Yet this is very simple, the per cent. of any grade, just like any other per cent., is the number of parts in a hundred, in this case, the number of feet rise in one hundred. The easiest way to figure grades is to reduce the length of the slope to feet and divide by one hundred, or what is the same, point off two decimal places. This gives the number of hundreds of feet. Now divide the total rise by this, and the result will be the per cent. of the grade.

Figured on this correct basis, the statement on page 833 of THE AUTOMOBILE should read as follows: "This gives an average grade of .24 per cent., and good braking will be at a premium. The next day, from Oakley to Salina, there is a drop of 1,818 feet but the distance is nearly 200 miles, so the average of grade is a little less than .18 per cent."

As very appropriate right here, a table of grades taken from *The Automobile Trade Directory*, is given herewith. In this the rise is given in feet per mile, but if this misleads anyone, it is a simple matter to divide the whole last column by 52.8, which reduces the figures found there to feet per hundred as described above.

TABLE OF GRADIENTS

Grade. Per cent.	Units.	Equal to Angle of	Rise in One Mile.
20	1 in 5	11° 19′	1056 feet
17	1 " 6	9° 26′	880 "
14	1 " 7	8° 09′	754 "
12.5	1 " 8	7° 08′	635 "
11	1 " 9	6° 17′	586 "
10	1 " 10	5° 43′	528 "
9	1 " 11	5° 11′	480 "
8	1 " 12	4° 46′	440 "
7.75	1 " 13	4° 24′	406 "
7	1 " 14	4° 05′	337 "
6.5	1 " 15	3° 49′	352 "
6.25	1 " 16	3° 35′	330 "
6	1 " 17	3° 22′	310 "
5.5	1 " 18	3° 11′	293 "
5	1 " 19	3° 00′	277 "
5	1 " 20	2° 52′	204 "
4	1 " 25	2° 18′	218 "
3.3	1 " 30	1° 55′	155 "
2.8	1 " 35	1° 38′	151 "
2.5	1 " 40	1° 26′	132 "

EIGHT-CYLINDER ENGINE

Editor THE AUTOMOBILE:

1,911]—Will you kindly give me the name and address of the firm making the eight-cylinder engine illustrated and described on pages 744 to 746, issue of "The Automobile" for May 6? Also would you explain if it will run as smoothly as an ordinary six-cylinder? F. R. BROSIUS.

Columbus, O.

The engine is named the E. N. V., after the firm making it, the latter also being called E. N. V. Motors, Ltd. The works are located at Rue Saint-Germain 23, Courbevoie, Seine, France.

The matter of smooth running depends upon the torque, which was discussed in full in the article in question, so that there is no necessity for going into it again and in this place. As for a direct answer to your question, this would be yes.

MORE ACID IN OILS

Editor THE AUTOMOBILE:

[1,912]—In re your reply to No. 1894, is it not possible to detect the presence of acid in lubricating oils with litmus paper?

Milwaukee, Wis. CHAS. W. NORRIS.

While litmus paper is extensively used for the detection of the presence of acid, it is believed that it is not delicate enough for this purpose, the amount of acid present in oil being usually very small. The methods given, on the other hand, are used for very delicate work, and will indicate correctly the presence of even the slightest trace of the destructive acid.

For the benefit of those who are not familiar with litmus paper, it might be described as an unsized paper saturated with a certain solution and cut into small short strips of perhaps one-quarter inch width by two inches length. One of these strips inserted in a solution containing acid, loses its natural colorless appearance and turns an angry sort of pink color. When inserted in an alkaline solution, on the other hand, it turns to a bright blue. The color is the same in the presence of much or little acid or alkali, so that at best its use but indicates the presence and not the amount of either.

It is repeated that the very small amount of acid in ordinary oil probably would not color the paper, so that its use, while possible, would indicate nothing. The test given in answer to 1894 was an accurate test, and shows not only the presence of acid, but also the amount.

SOME ANCIENT HISTORY

Editor THE AUTOMOBILE:

[1,913]—Your recent editorial on tire sizes is correct and along right lines, but your history is slightly in error. Large-sized tires have always been obtainable and the Duryea which won the first American auto event in November, 1895, was fitted with 44-inch and 48-inch single tube tires of 2-inch section. The three Duryeas which scooped all prizes in the second event, the Cosmopolitan race, Decoration Day, 1896, were fitted with 34-inch and 38-inch tires of 2½-inch size, single tube. A few Duryeas were built in the next year or two with 30-inch and 34-inch tires, but the standard of 30-inch front and 36-inch rear, both 3-inch size, was adopted in 1898. The first few of these were single tubes, but the Dunlop tires of those days were not made in molds and so could be had in any size desired and they were adopted shortly after this and used steadily since. Duryea Buggyauts are fitted either with these sizes of pneumatics or with 38-inch and 44-inch solids of 1¾-inch and 1⅝-inch size. Being identical in construction, they give a chance to compare the results as your wish expresses.

No very sccurate comparisons have been made, but the difference is noticeable. The small wheels drop into the holes in the road and toss the riders more than do the large wheels and solid tires. On the other hand, the air tires swallow the rocks and stop the myriad small vibrations much better than the solid rubber on the large wheels. The air tires and small wheels do not roll so easily ordinarily, for the large tire must flatten the dust, sand, mud or snow, whereas the narrow tire cuts through. At speed the favor is with the air tire, but the best time between Reading and Philadelphia is held by the car with solid tires and large wheels. My feeling is in favor of large wheels with solid tires. That if fitted with pneumatics, they would be better goes without saying.

In my experiments I have simply tried to get the size of wheels which, with solid tires, would ride practically the same as the most-superior, commonly-accepted air tire sizes.

I have also experimented with solid tires of same wheel diameter as the pneumatics, but although these were as large as 2-inch or even larger, they were noticeably objectionable. The large wheel has merits that can not be denied. Just how large the wheels can be with good results I do not know. Carriage makers, after generations of use and experiment, stick pretty close to 44-inch front and 48-inch to 50-inch rear. Roads are slowly getting better, which will allow slightly smaller sizes. Auto speeds are higher and being fitted with better rubber or air tires, the auto wheels should be somewhat smaller. Having satisfied myself that 36-inch is the low limit for wheels that carry much load, I do not look for much increase above this.

Makers generally will hold to the lowest that the public will take. That this limit is not a guess is pretty well proven by the fact that users of Duryeas seldom carry an extra tire. Extras are confessions of weakness. One user writes me in the last few days and says "Two of the tires have not been off the rims in three years and still folks complain about tire troubles."

The reason why small tires were used was because the maker wanted to save money snd so supplied the smallest tire he could get the public to take. Further, the tire maker guarsnteed the product, so the maker had very little care as to what size went on. Not till the makers kicked did sizes increase. Yet many of the older makers fought hard for larger sizes. Haynes, for example, stuck to large wheels from the very first. Winton did much the same. The toy steamers are largely responsible for saddling the industry with bicycle-sized tires. Certain it is that practical rigs should never have used them, and a large percentage of our auto troubles have arisen from wheels too small, with consequent discredit to the industry.

CHARLES E. DURYEA.

A MACHINE OF ABSORBING INTEREST TO FARMERS

DRUDGERY marks much of the daily routine work of the average farmer's life, and any device which promises to reduce this purely repetition work of the farm, and is not too radical, is finding ready adoption among the up-to-date tillers of the soil. The invasion of the country districts by the automobile is an accomplished fact, so that a machine resembling an auto or having a similar source of power would not come in the "too radical" class. For this reason as much as for its intrinsic merit a newcomer in the farming machine line, constructed by a Western man and herewith illustrated, will find instant favor with the farmers.

Rear View, Ready for Stacking

It is called a "hay-buck and stacker," from the work which it is intended to perform, namely, that of collecting hay from the fields, bringing it to a central point, and stacking it there. In addition, however, a number of attachments may be made to the original hay-buck, fitting it for as many other duties, and by their very large number making the whole machine a farming implement applicable on every farm, by every farmer.

The "Hay-buck" is the invention of Jacob E. Liebhart, a rancher residing near Los Angeles, Cal. Mr. Liebhart's prime idea was to reduce the hardships and expense of farming by means of a mechanical device which would do the same work at the expense of a less number of horses and a largely decreased number of farm hands.

After proving out the first machine to his satisfaction, he added, without impairing the original functions, successively a plow, a cultivator, seeder, cutter bar, rake, scraper, ditcher, and grader. The additions take the whole machine out of the class of specialized machinery for a single line of work, and thus suitable only for large ranches where the expense of a machine is trifling in comparison with its annual saving, and by making it able to do grinding and cutting of feed, weeding, pumping water, harvesting beans, beets, etc., and many other kinds of work always done heretofore by horses, puts it into the class of minor economies, which every farmer must practice to compete with his natural opponents, his neighbors.

The machine is propelled by a two-cylinder vertical 20-horsepower automobile engine, and may perform all of its functions with the assistance of but two men.

A Comparison with Old Methods—With the horse-operated hay-buck and stacker, as used at present, eight horses are required, as well as three hay-bucks, a stacker, wire cable and the other parts to make up a complete outfit for moving hay from shock to stack. This outfit costs about $1,500 and requires seven or eight men to work it at an average cost of $20 per day. Its use is restricted to two months of the year, and during the remaining ten months must stand idle, in which situation it represents unproductive capital in a place where capital is scarce and every dollar should be at work all of the time.

In case of accident or delay the expense of both men and machine continues, and even while in use the deterioration is large unless the machine is carefully housed. When not in use the very size of the old-fashioned machine calls for excessively large storage houses; moreover, a large space is required for operation and wide bridges for its accommodation when moving from place to place. All of these items, added to the large amount of money tied up, made it expensive to possess.

Horses Are Both Crude and Clumsy—Added to the economical reasons which militate against the older form, the sources of power—horses—are crude, hard to handle and awkward in operation. Each team averages about one and a half miles per hour. A team drives out, picks up three shocks of hay, turns and pushes back to the stack. After unloading they back off, turn again and are driven back to the starting place to begin over. At the stack the load is hoisted and dumped at a considerable loss of time, and at best in a tangled mass. This is difficult to handle, and requires the laborious efforts of three men, whose efforts are greatly hampered by the necessity for dumping all of the hay in one spot. This is required by the fact that the stacking machine remains stationary during the completion of a stack.

The single position also results in producing an uneven stack, which is solid in but one place, both of which items add to the cost of baling. Not only does the work of the horses cause trouble and the inherent difficulties of stacking add to this, but the day's "stunt" is frequently decreased by the breaking, kinking, cutting or heating of the cable.

A stack having been completed, much time is consumed in moving to a new position, during which interval the men and machine are busy, but producing no effective results.

Newer Method Saves Both Time and Money—The "Auto-Hay-buck and Stacker" combines all of the parts into a single machine, requiring but two men to attend it, horses being eliminated. The two men are placed, one on the machine and the other on the stack. Cost of operation falls in this way to less than $7.50 per day, almost one-third of the previous cost for labor alone. On the operation of bucking and stacking hay the automatic averages from four and a half to five miles per hour, over three times what the best horses can produce. Moreover, the machine runs equally well backward or forward, so that no time is lost in turning or backing. The engine can approach the stack from any side, so a more symmetrical stack results, this being effected with less men and less labor on the part of the men. The man on the seat of the machine has a comfortable seat, and by changing off with the man on the stack both are more comfortable all of the time, and thus able to do more work, or, if necessary, to work longer hours. The resulting stack being even, is baled more readily and quickly.

There are two sizes of the machine as now built, and the smaller, which is suitable for the ordinary small farm, costs about $1,500. With all of the various attachments it can be worked continuously in the field, in the grading camp, on the road during the

Seen at Closer Range When Starting a Stack

Six-Horse Team of the Nineteenth Century Hauling Ore on Desert Road

day and pumping water at night. It can be handled or stored in a small space, and will cross normal-sized bridges.

Easy to Understand and Operate—In case of accident or delay but two men and no horses are standing around idle. The mechanism, being simple, is readily repaired, and the same simplicity makes it easy to operate. The automobile engine used is beginning to be familiar on the farm, and the operation of the hay-buck is therefore easily understood.

From a humanitarian point of view, it is a distinct advantage as well. The process of stacking and bucking hay is a hard one, the ground around the stacker gets cut up to quite a depth and makes the work hard on the horses, while moving the stacker is equally hard on them.

OLD AND NEW ON THE DESERT

By H. H. DUNN.

Side by side on the old Dagget road, which leads from the mining camp of Ord to the old town on the Salt Lake railroad, twentieth century methods are competing with those of the nineteenth century.

Once a narrow trail, followed by creeping burros laden with sacks of ore heavy with gold, the way has been widened until it has become a broad path from camp to town. First to cause this widening were the teams of six to twenty horses driven by the men who hauled the ore down to the railroad cars. But now has come a new conqueror to the desert.

All the terrors of the waterless, sunburned road have given way to this new steel monster, which, carrying its own food and water, eats up the miles relentlessly, drawing behind its broad wheels—for it is a modern improved traction engine, built especially for the desert—wagons which carry fifty tons of ore where the old horse-drawn wagons carried ten.

Progress with the new tractors is as fast as the walk of the teams that once pulled ore wagons over this trail, and today the engineer waves his hand to the teamster as each gives half of the road to the other in going to and fro between the camps. But the horses and their drivers are fast passing from the trail; where once were dozens of these teams there are now only the few whose contracts with the mining corporations give them sufficient work. The steam tractor, which has recently conquered the terrors of Death Valley and is now making its way into other parts of the desert, is taking their place and doing the work of several teams at less than the cost of one.

For some of these engines fuel is brought in in the shape of tanks of oil, but the roots of the greasewood bushes alongside the road furnish most of the material with which steam is kept up. Water is obtained from the same storage tanks that supplied it to horses and men on the trail in former days, with this in favor of the tractor, that less water is required than for the animals. As it is, the thread of smoke and the screaming whistle of the tractor trailing its trains of hundreds of tons of ore over the level floor of the great sand plat present a vivid contrast to the long lines of horses and the choking clouds of dust that once crept slowly over the same trails.

Steam Tractor of the Twentieth Century Hauling Ore Over Same Trail

CLEVELAND TRADE IN INDUSTRIAL DISPLAY

CLEVELAND, June 7—Automobiles play an important part in the Cleveland Industrial Exposition which opened here this evening. The exposition is solely for the benefit of Cleveland manufacturers, and is intended to boost home industries. All kinds of manufactures are included in the exposition, provided they are located within the limits of the city of Cleveland.

Not even the originators of the movement realized how the automobile manufacturing trade had progressed of late.

All the local factories are exhibiting, including Stearns, Peerless, Royal, White, Gaeth, Winton, Baker, Rauch & Lang and Broc (electric), while all the many parts and accessories made in the Forest City are also shown. The Elwell-Parker Company, manufacturer of electric chassis, has quite a display, while the Perfection Spring Company and many others are prominent.

Farmer Thought Auto Was a Locomotive—Down in Texas it is said that there is a greater demand for automobiles than in "any other State of its size in the Union," but at least one man there was not familiar with the auto until recently. He was then forcibly introduced. In walking along the road he was struck by an auto whose driver had blown his horn loudly and expected that the pedestrian knew what was coming. After taking account of stock the farmer said that he had heard the horn, but thought that it was a locomotive on the nearby railroad.

HEAT VALUES OF ORDINARY AUTOMOBILE FUELS*

By DR. FRITZ HUTH, Berlin, Germany

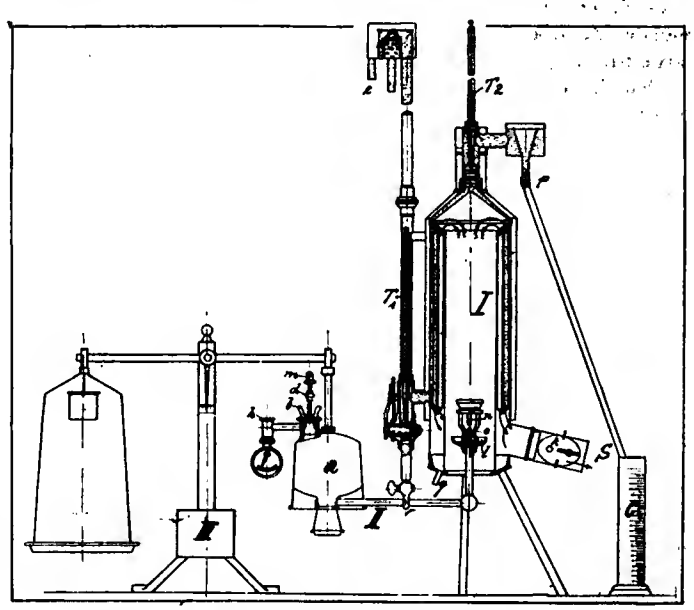
CONSTANTLY increasing expense for fuel has brought the automobile industry to the necessity of providing a cheaper combustible for this purpose, unless the economy of the commercial motor wagon, which has given such promise for the future of the industry, should be given a setback by being placed in question solely on account of the high price of benzine (gasoline). This has led at an earlier date to the undertaking of an investigation by the industrial protective bureau into the merits of home products, such as alcohol, without, however, having reached a successful conclusion as yet.

Now that so many new fuels have been placed on the market about the same time, the field is much wider than previously. Therefore, it is necessary that the driver who is in doubt as to how far the recommendation concerning a new fuel may be accepted, or whether it is adapted for use in the carbureter of his motor, or whether its use will be detrimental to the motor itself, should know how many heat units per kilo the new combustible contains. All these various questions cannot be referred to the single test mentioned of the fuels concerned for an answer. Not alone what may be the heat value of a certain fuel, but also what is the maximum allowable price to be paid for it, are questions of considerable interest. Consequently, with one of its most important characteristics definitely determined, a relative value may be assigned to it. Likewise, its standard of specific gravity will also be known, this being ascertained with the aid of a hydrometer.

For determining the heat value of the fuel, a Junker calorimeter is employed, and as this is an instrument not generally known, except to the technical fraternity, a short description of its construction and method of working will be of interest. It consists of the peculiarly shaped oven or combustion chamber I, surrounded by a water jacket, and the lamp II, suspended from the beam of the scale III. The lamp, which is of the ordinary type used for soldering, consists of the reservoir *a*, through the opening of which, *b*, some 200 cubic centimeters of the fuel to be tested should be poured. The burner *n* consists of a spray nozzle through which the combustible must be forced before arriving at *o*. *D* is a valve, and *m* is the cap belonging thereto, while *h* is a screw on the pressure gauge by means of which the operator may regulate the amount of air pressure on the fuel in the reservoir of the lamp. The apparatus is made ready for operation by burning a little alcohol in the cup of the burner *l*, in order to heat the latter, or it may be warmed with the aid of a Bunsen burner. A small hand air pump is then connected up with the valve *d*, in order to place the fuel to be tested under pressure.

Operation of the Apparatus—The liquid combustible then rises to the height of the burner, is sprayed out of the nozzle, and burns with a lightless flame. When the opening of the spray nozzle is properly regulated, gas pressure is created, which is held in equilibrium by the pressure on the interior of the vessel *a*. The lamp, which will now continue to burn without further attendance, is so placed on the end of the arm of the scale in order that it may project into the combustion chamber as far as possible. The hot gases rise in the direction indicated by the arrows, then being deflected downward again through copper tubes and finally escaping into the open air through *S*. The butterfly valve *k* serves as a means of regulating the draught through this opening. The tubes are filled with water, which as it expands through heating overflows into *c*. In a by-pass formed by the filling tube of this water jacket, consisting of the tubing mentioned, is placed a thermometer calibrated in tenths of degrees, T_1, while at the top of jacket just before the overflow is reached there is a second thermometer of the same type, T_2. Thus the temperature of the water upon entering and leaving the apparatus may be taken. The water escapes at *p*, and at this point as well as at *e*, the inlet, an overflow is provided in order to equalize the pressure of the water throughout the apparatus. The outlet *p* is provided with a rubber sleeve by means of which an extension tube is attached to it in order to conduct the overflowing heated water to the measuring vessel *e*. The hot gases give up their heat to the cold water so completely that it flows out at an almost constant temperature. The small outlet *q* permits of the escape of any water of condensation, an accurate measurement of the quantity of which is necessary to the determination of heat values.

A small weight is placed in the scale pan seen depending from the reservoir of the lamp *a*, and the investigation proceeds automatically as already described until sufficient of the combustible under test has been consumed to permit the pointer of the scale to return to the zero mark. The moment this occurs, the tube



Calorimeter Arrangement Used in Determining Heat Values

extending from *p* is dropped into the graduate *c*, and another weight, say 10 gr., is placed in the scale pan. As soon as the amount of combustible represented by this weight is consumed the pointer of the scale again touches the balance point, and the tube from *p* is immediately withdrawn from the graduate and the amount of water which has overflowed into the latter is determined. In the meantime both the thermometers, T_1 and T_2, have been read several times. The amount of water escaping at the outlet *q* has also been collected in another graduate.

Method of Figuring the Results—Results are arrived at by taking the number of liters of water *W*, overflowing from the apparatus, with relation to *T*, the temperature difference as recorded by the thermometers, T_1 and T_2; *G*, the weight of the combustible consumed during the course of the experiment, and calculating the number of heat units evolved by the formula:

$$H = \frac{W.T}{G}$$

This represents the higher heat. The lower heat is found by taking the number of cubic centimeters of water of condensation for each 10 grammes of the fuel burnt and multiplying by 60, the resulting quantity then being subtracted from the result given by the calorimeter for the higher heat value of each kilogramme of liquid.

With each variety of combustible at least three or four experiments should be carried out. 10 grammes of the fluid being

*Translation from "Der Motorwagen" (German).

burnt and the temperatures read from minute to minute. The values given in the following table are the mean averages of these experiments. The figures given are the results of 50 tests. Even the heat value of lubricating oil has been ascertained, because in calculating the efficiency of a certain fuel for motor operation the high heat values of the lubricant that is burned should not be neglected.

As mentioned at the outset, the heat value alone cannot be taken as affording a certain and final indication or measure of the worth or economic value of a fuel. In order to arrive at this many other factors must be taken into consideration, such as its entire performance under varying conditions and speeds, as well as with various types of carbureters, and this will be the object of an investigation to be given later.

HEAT VALUES AS EXPERIMENTALLY DETERMINED

Fuel.	Spec. Grav.	Higher heat Values.	Lower heat Values.	Price per 100 kg. in marks.

THE AUTOMOBILE AS A FEEDER OF CIVILIZATION

By HERMANN F. CUNTZ, A. L. A. M.

IN 1898 there were not more than 200 automobiles made and put into use in the United States. In 1909 the total number of automobiles made and sold in the United States will approximate 82,000, the members of the Association of Licensed Automobile Manufacturers, as in the last six years, playing a very large part in producing the machines.

That the automobile is a marvelous piece of mechanism is seen when it is considered that less than thirty years ago prime movers weighed as much as 800 or 1,000 pounds per horsepower developed, and that the modern automobile engine has been reduced in weight to well under ten pounds per horsepower developed, and has shown its great reliability by running for days without stopping. This perfection of engine construction has been paralleled by perfection of the other elements of the motor vehicle—all accomplished in the commercialization of the last eight years by progress in design, material and workmanship.

The advantages accruing from the use of the automobile to the human race and the industrial world are so great as to, in any fair consideration of the subject, more than counteract the occasional narrow-minded view fostered by thoughtless elaboration of unfortunate details necessarily incident to the process of the introduction of motor traffic.

In 1907 there were accidents on railroads in the United States to 110,000 people, and over 10 per cent of these accidents resulted fatally. Still, of course, the railroad is always considered an essential thing in any country.

The horsepower of which the average automobile produced this year is capable is about twenty, the 82,000 machines making an aggregate of 1,640,000 horsepower. At the beginning of this year there were in use in the United States over 184,000 automobiles, capable of close to 4,000,000 horsepower. The harnessing of water power at Niagara Falls to the extent of a few hundred thousand horsepower was hailed as a stupendous accomplishment.

Considering the passengers carried per mile by railroads in the United States in 1908, as compared with the number of people carried per mile by automobiles, we find that in the same time and territory automobiles furnished seven-tenths of 1 per cent of the number of passenger-miles the railroads furnished. What will the relative percentage be in 1915? Taking the rate at which railroad construction and traffic and the use of the automobile are increasing, at a conservative estimate, the automobile will provide 7 per cent as much passenger traffic as the railroad.

In small freight transportation the motor will gradually supplant the horse, on account of less cost and greater convenience.

Before ten years shall have passed 10 to 15 per cent of the American farmers will own automobiles.

The railroads of this country have spent, as charged to cost of construction and equipment, over thirteen billion dollars; practically within the last forty years. It is futile to gainsay the fact that an expenditure on the common highways of this country in the next forty years of a sum equal to the private outlay on railroads in the last forty years would be anything more than warranted, reasonable and wise.

Six Best Shots in the World, in a Winton Six, at Hill Top Gun Club, Paris, Kentucky

Walter Christie's Front-Drive Autocab

SEEKING the unusual, one can find much of interest in the just-completed Christie front-drive cab, which the manufacturer and inventor, Walter Christie, of Eleventh avenue and Twenty-third street, New York City, says is the only proper solution not alone of the complicated cab situation, but of the question of ultimate drive for all automobiles.

Mr. Christie is a versatile inventor, having to his credit the revolving turret for warships, a very efficient form of packing for steam pistons of large diameter, and other innovations. But his pet is the combination front drive and front steer, to which ignorant and unthinking ones have applied the title of "freak." This really is a misnomer, for it presents nothing of the odd or whimsical, as freak is defined, but, rather, contributes ideas worthy of much thought.

Not only is the new car, which is of small power, comparatively light weight and suitable primarily for taxicab use, equipped with a front drive, but the block motor shows a number of carefully worked out details, while the transmission is a masterpiece of rugged yet small and compact work. The wheels, too, designed by Christie especially for cab work, are based upon an idea which may be generally adopted before long.

All engineers are aware that in cam and roller actions sudden movements demand that the cam surface traveled over by the cam-roller should always turn in a direction away from the point of roller-lever hanging, and that cam actions so sudden in angular variations that they will not run at all when the cam runs towards the axis, run smoothly and at high speed when the cam is turned the other way. The road surface and the vehicle wheel form an exact mechanical parallel to the cam and cam-roller, and every motor car rider is well aware that in all cases of hard work with rear wheel driven cars, the rear wheels try to go ahead of the front wheels, and often succeed in doing this, much to the agitation of the passengers.

Mechanically the Situation Is Grotesque—When it comes to driving with the rear wheels and steering with the front wheels the situation becomes mechanically grotesque, the suitability of steering with the driving instead of with the driven wheels being so wholly obvious. With rear wheel driving and front wheel steering, the front wheels can be given only a small angle, as they are pushed sidewise by the drivers, and cannot be given nearly so short a radius angle as is desirable. Where the front wheels are both drivers and steerers, the front axle can be turned square around at 90 deg. to the pulled, trailing rear axle, same as a truck driver heads his horses crosswise of the road when he wants a short turn, and the car will start with ease.

All of this has long been known, yet automobile builders put the cart before the horse, and assert their own wisdom in so doing, although in point of fact only one single valid argument can be brought forward in favor of rear wheel driving. But this one is potent; rear wheel driving is the accustomed thing, and therefore the easy thing to sell, although it has a full list of faults and not one virtue as compared with front wheel driving.

More than one auto builder has tried front wheel driving and steering, notably in the German "fore-carriage," pushed to failure some years since, some experts claim, simply because it was not suitably designed and constructed.

The greatest advantage of front wheel driving and steering is the pull instead of the push, and the possibility of turning in a circle having a diameter equal to the wheelbase plus one-half the gauge. There is, however, a secondary advantage, which is alone and of itself amply sufficient to call for serious consideration of motor-cab front driving and steering. This is the possibility of a front motive and steering assembly of small dimensions, entirely self-contained and very readily detachable from the remainder of the chassis and car-body assembly.

This means that with one extra fore-carriage for, say, every ten cabs, the whole ten can be always kept in working condition with only the one small fore-carriage assembly in the repair shop, and all ten of the bodies and rear wheels assemblies out on the street earning money. With the rear wheel drive any failure back of the motor puts the whole car on the sick list, if, indeed, the motor is so constructed as to be readily removed from the car, which is very seldom the case.

Summation of Front Drive Advantages—Summed up, the front drive arrangement conduces toward the elimination of skidding, because it has been found by experiment that the free rotation of the rear wheels, which, by the way, is only found in the front drive, practically reduces the question of side-slip to a negligible quantity. Various attempts have been made to solve this problem by the use of front instead of rear brakes. This is on the order of a half-measure, and as such is a waste of time.

While the inventor has yet to build more than the one cab, the details of this as embodying a principle that is fundamentally correct are worthy of mention.

Engine Set Across the Car—The first radical point of difference is noticed in the position of the engine, which is set across the frame, at right angles to the ordinary practice. Moreover, it is combined with the front axle in a detachable way, a two-speed and reverse transmission being interposed and an expanding band clutch is utilized.

The four cylinders of the engine are cast in a unit with the upper half of the crankcase. The bore is 3¼ inch and the stroke 5 inch. The engine is slated to deliver at least 18 horsepower, which it does easily at 1,500 r.p.m. The top of the cylinder block, comprising an opening for the core print of perhaps 5 inches wide and 14 inches long, is normally covered by a plate,

from which the water outlet arises. The lower half of the crankcase, with the supporting feet which tie it to the front axle casing, is one of the other parts, while the cover for the gears at the front of the engine completes them. The drawing showing the construction displays the careful designing incidental to the building of the car in a number of ways. The metal between the cylinders is 1-4 inch, but at the ends, where there is less necessity for this amount of metal, it is reduced to 7-32. The water jacket thickness is right down to the limit of good foundry work, 1-8 inch.

The pistons have the pin fast in the rod, this being of 3-4 outside and 7-16 inside diameter. To care for the wear of the pin rotation, the piston bosses are bushed with phosphor bronze. The piston is of good length, 3 3-4 inches, and fitted with three 3-16 rings, all above the pin. These are cut diagonally. The connecting rods are of the usual I-section, the ends being 1-2 inch wide. Two bolts are used to hold the big end bearing, and these are of 3-8 diameter and special steel. The offset of the rods necessary to allow the central bearing being used is 1-2 inch.

Crankshaft Shows Excellent Design—In the mainshaft, the heart of the engine, is shown the ability of the designer. This is of as large diameter as is consistent with the power, the crankpins being 1 1-2 by 1 7-8 long. The bearings, on the other hand, are even larger than this, being 2 1-2 inches in diameter, with the end ones 2 1-8 long and the center 1 1-2 long. The bearings are plain, following usual practice. The shaft is very short, less than 18 inches over all, which short length, coupled with the three bearings, should make for great rigidity.

The engine is water cooled, the water circulation being very short. From the top cover plate there is a short pipe leading to the center of the tank forming the top of the radiator. The rest of the cooler consists of two banks of vertical copper tubes, about 280 in each, arranged at the outside of the car. The base of the radiator is another tank, into which the copper tubes are brazed, and into which the water flows in two streams from the two sides of the cooling surface. From this lower tank another short pipe leads to the pump, of bronze and medium diameter, which pumps it into the cylinder block at the base of the water jacket between the two central cylinders.

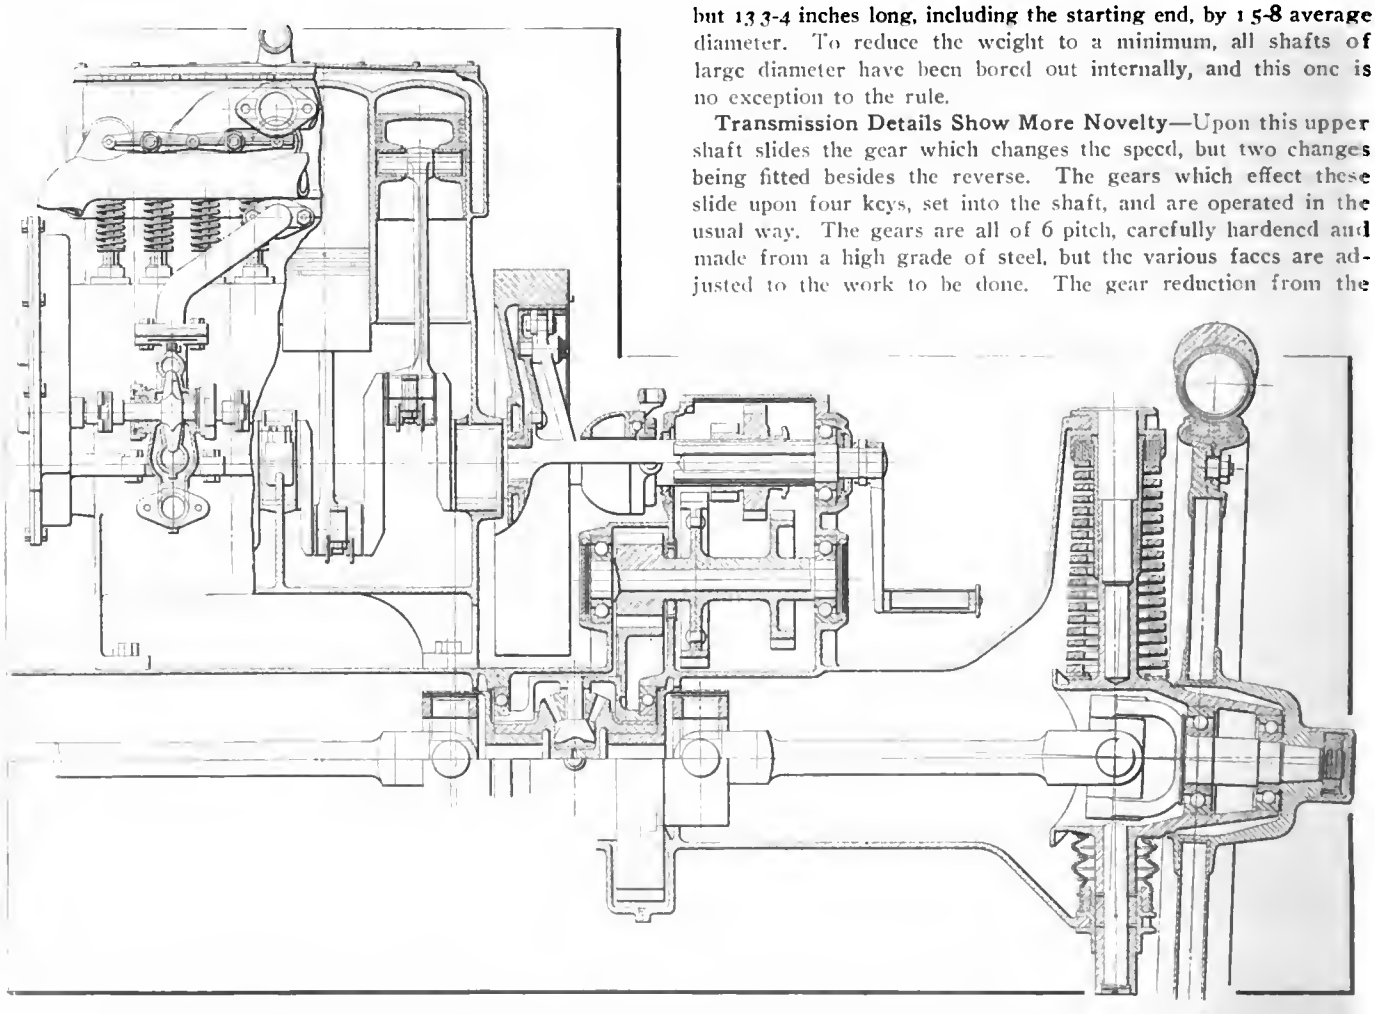
The pump is of bronze, with stuffing boxes on each side, and is driven by a special auxiliary shaft, which also drives the magneto, placed on the same side of the engine, the inside towards the radiator. The pump is driven through a pair of couplings one on each side, which allow of its ready removal.

The air to cool the water is drawn through the banks of tubes by a fan belt driven from the flywheel, and hung on a bracket which is movable, the movement being such as to alter the tension of the belt. The usual position of the engine makes that of the fan axis, which is parallel to it, equally unusual, namely, across instead of parallel to the car.

At the right-hand end of the engine shaft is attached the flywheel, which, of 14 inches diameter, with a rim 2 3-4 wide by 1 1-4 thick, aside from balancing the engine so as to produce even and regular rotation, also carries the clutch within it and safely covered from the dirt and dust. This clutch is of the internal band type, expanded into place by the action of a toggle, which is in turn actuated by the sliding forward or back of a conical-shaped piece upon the surface of which the rollers of the clutch rest. The clutch is of 1 3-4 face and 11 1-2 inches diameter.

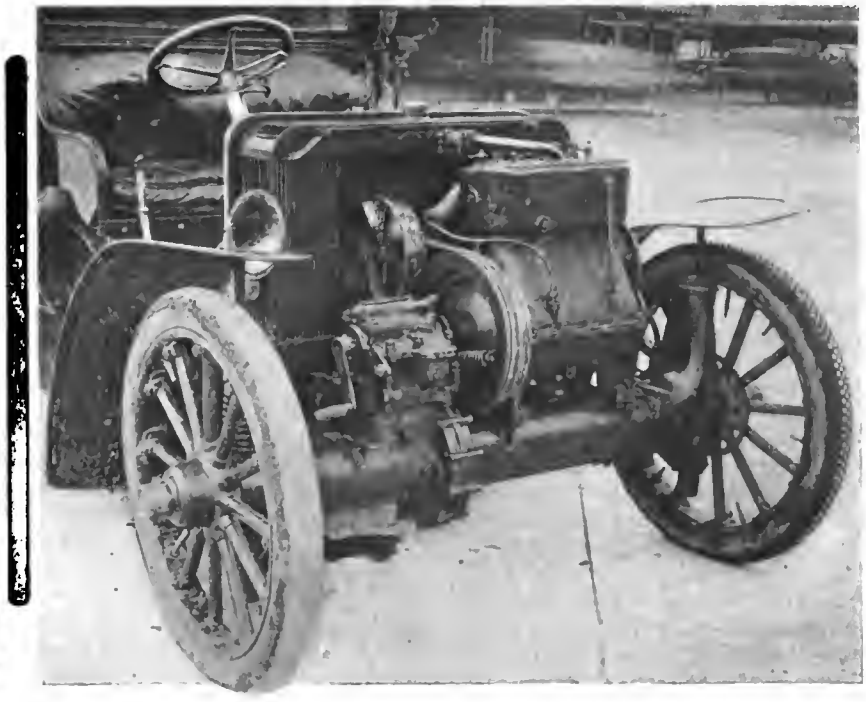
The disposition of the clutch shaft, which is at the same time the main or upper shaft of the transmission, is peculiar. The large diameter end of the crankshaft is turned out to receive a bushing at that end, within which bushing the forward end of the transmission shaft turns. This bushing is plain, but the one at the other end is of the radial ball type, also arranged to take thrust. Like the crankshaft, the mainshaft is very stubby, being but 13 3-4 inches long, including the starting end, by 1 5-8 average diameter. To reduce the weight to a minimum, all shafts of large diameter have been bored out internally, and this one is no exception to the rule.

Transmission Details Show More Novelty—Upon this upper shaft slides the gear which changes the speed, but two changes being fitted besides the reverse. The gears which effect these slide upon four keys, set into the shaft, and are operated in the usual way. The gears are all of 6 pitch, carefully hardened and made from a high grade of steel, but the various faces are adjusted to the work to be done. The gear reduction from the



Christie Front Axle, Motor, and Transmission Assembly Looking Forward from the Driver's Seat, Partially in Section

The Control Is Standard



Full View of Front Axle Construction Shows Starting Handle at Left

engine to the road wheels is 4 to 1, and on the low speed just half of that, or 8 to 1. Thus, the gears for the high speed are but 7-8 face, which is increased to 1 inch on the low. This, in turn, is increased to 1 3-4 inches in the gear which carries the final drive to the axles.

This is right below the transmission, and the drive from the latter is by spur gears. The final gear, upon the axle, is attached to the housing of the differential, which is of bronze. The differential, of the bevel type, is located near the center of the axle, the casing of which is split at that point to permit the ready removal of the parts. On each side of this case are large diameter ball bearings, beyond which are the first pair of universal joints, one on each side. From this point to the ends a pair of 1 1-2 shafts transmit the power to the wheels through the medium of another pair of joints, the latter being located in the exact center of the wheels. This location makes the function of steering easy, for the wheels rotate around the same center about which they move to effect the steering. The axle is housed within a cast bronze tube of 6 3-4 inches outside diameter with 3-16 walls, which is what gives the front view of the car its bulky appearance.

This Form of Drive Calls for Different Springs—Upon the ends of the axle housing are placed the springs, which, from the very nature of the construction, are radically different. They are of the coil variety, the outer diameter of the coil varying from 3 1-8 at the top to 3 3-4 at the bottom. The steel comprising the coils is rectangular in section with the longest side in a horizontal plane. The section is 5-8 by 1-4, and each one has 18 full coils. Above the top end and under the lower extremity are placed bronze thrust washers.

What corresponds to the knuckle pin is of very large size, 1 1-2 diameter, bored out inside to 7-8 inch, and projects above the universal joint casing 6 1-2 inches, of which 3 inches has a bearing when the car is not loaded, but with heavy additions to the load this may increase up to 6 inches.

Upon the stub axle end the wheels run on a pair of ball bearings of large size. These are located very close to the line through the wheel center, the inner one being but 1-8 inside of the center of the tire and but 1-16 outside of the center line through the spokes. The axle stub at the inner bearing has the unusual dimension, for this weight of car, of 1 3-4 inches, which decreases to 1 9-16 at the outer one, but 2 5-8 farther away.

Beyond this the end tapers, and upon this taper is mounted the heavy hub, which is held in place on the taper by a nut, cottered in position, and further retained in place by the hub cap, which would effectually prevent it from backing off, even if the cotter pin were forgotten.

The rear axle is of very simple construction, and is as plain as is consistent with the fact that it carries nothing but the springs and the large-sized brake drums. These brakes are internal expanding, and are operated by means of a cam.

The front wheels incline outward so that the tire centers are one inch farther apart on top than at the bottom, while the gauge is 52 1-2 on the road. With this small tread, a wheelbase of 100 inches, and the large angle of steering possible, the whole vehicle may be turned in a radius of 12 1-2 feet, or in a 25-foot circle. Steering is effected by the medium of a worm and sector, with a diagonal connecting rod to the left knuckle and a straight rod joining the two wheels, the latter being placed in the rear of the axle, where it is protected.

Even the Wheels Show Marked Ingenuity—The construction of the wheels is a far cry from what one would expect, for, beginning with the hubs just spoken of, the whole wheel is radically different, these having been designed especially for the cab service. The requirements may be summed up as: exceptional strength, particularly for side strains; lightness, and of a shape or form which lends itself to quick replacement. It is well known that the steel tube is, weight for weight, one of the strongest shapes made, and it is of this shape that Christie has constructed his spokes, thus obtaining at a bound both strength and light weight. These steel tubes are forced into seats machined in the hubs and then clamped to the felloes with retaining bolts, which hold on the loose flange of the rim as well. In this manner a new felloe and inflated tire may be substituted for a deflated or punctured tire in the time it takes to tell it. By using bolts, brazing is dispensed with and the quick tire change made possible. Both front and rear wheels are the same size, 32 by 3 1-2. This seems like a small size, but in view of the light weight, 2,100 pounds, is ample.

The body is the regular cab equipment of landaulette body, but the bonnet varies, being more like the style affected for so many years by Panhard. It pulls forward for removal, but for cases of ordinary trouble the top portion may be raised. The starting crank may be seen at the left side of this bonnet.

The price of the cab, complete, ready for the road, with lamps, horn, tools and spare parts, is $2,600.

CONNECTICUT LAW NOW UP TO HOUSE

HARTFORD, CONN., June 7—Now before the House of the State Legislature is a bill, already passed by the Senate, which has been introduced as a compromise for the law proposed early in the session, and the new one bids fair to pass. One of the features, which caused so much discussion in the previous bill, was that giving the control of automobiles and the like to a supervisor of motor vehicles, but in the present form the secretary of State will have charge as heretofore. The substitute bill also makes the speed limit 25 miles an hour, provides a rather large license fee for cars of 40 horsepower and over, and states that all cars must be muffled between 9 P. M. and 6 A. M. Siren and exhaust horns are also prohibited.

The fee for motorcycles is set at $1; for commercial vehicles regardless of power, $5; for automobiles controlled by liverymen, $10; for cars of manufacturers, $100, and for those owned by or under the control of a dealer, $20. Private owners will be subject to the following charges: For cars of less than 20 horsepower, $6; cars above 20, but less than 30 horsepower, $10; cars above 30, but less than 35 horsepower, $15; cars above 35, but less than 40 horsepower, $20; cars of 40 horsepower or above, $40. Non-residents will be allowed to use the highways of the State for a period of 10 days without taking out a license, providing that they carry the tags of their home States.

As is the case in most of the laws which have arisen in the various commonwealths this year, the speed proposition provides that autoists shall operate their cars at a speed no greater than is reasonable, and then stipulates that anyone traveling at a rate of more than 25 miles per hour, for a distance of an eighth of a mile, may be considered as being driven recklessly. Of course, there are the familiar provisions as to passing fractious animals, and if the car is in a crowded section of a town the limit of sane driving is 10 miles per hour. Three miles per hour is allowed an automobile when it is about to pass a trolley car which has stopped to discharge or receive passengers. All money received by the Secretary of State must be turned over for highway improvement at the instance of the commissioner.

SENATORS FAVOR AMERICAN AUTOMOBILES

The recent tariff discussions have brought out some very interesting side lights. Take, for instance, the following conversation which occurred during the discussion of the tariff bill before the Senate, the subject being the status of imported automobiles, and the sentiment expressed being a boost for high-class American cars, with the Packard used as an example. The excerpt below is from the *Congressional Record* of May 21:

Mr. Aldrich—It is not correct. There are at least half a dozen leading makes of automobiles that are imported largely.

Mr. Bacon—I have no information on the subject myself.

Mr. Aldrich—Eight or ten makes would include certainly most of the importations.

Mr. Bailey—If we could have the name of the maker and the country from which they come engraved on them, we would tell which Senators are riding in imported automobiles.

Mr. Aldrich—The foreign makers look out for that.

Mr. Hale—The Senator need not be alarmed about that. The marks will be on the machine.

Mr. Bailey—According to my belief, the marks of the people ought to be on some of the Senators who ride in imported automobiles.

Mr. Aldrich—I hope no Senator would ride in an imported automobile.

Mr. Bailey—I saw the Senator from Rhode Island riding in a very costly finished one and I wondered if it was made in this country.

Mr. Aldrich—It was made in this country. It was made in Detroit, Michigan.

Mr. Smith, of Michigan—We are very proud of it.

REEVES TAKES A WESTERN TRIP

Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, left New York City Wednesday night for a tour of the Western factories. Incidentally, he may have a look at the Crown Point road races of next week.

EDGE HURRIES BACK TO ENGLAND

S. F. Edge, the well-known British autoist, and one of the big factors of Napier interests, sailed for home yesterday on the *Lusitania,* apparently quite well satisfied with his short American visit. In fact, he contented himself with the statement that he may return very shortly.

This means that there is undoubted truth in the story that the Napier Company may have an American factory of considerable magnitude. For several years an American company has built Napiers under a license from the parent concern, but this new project is understood to be entirely separate.

Mr. Edge created a decidedly favorable impression, and he frankly admitted being impressed with many things which he noted.

N. A. A. M. COMMITTEEMEN MEET AND TALK

NEW YORK, June 7—At the regular monthly meeting of the executive committee of the National Association of Automobile Manufacturers, held in the association rooms June 2, John N. Willys was elected to the board to succeed Col. George Pope, representing the Toledo Motor Car Company. Routine business matters were considered. William E. Metzger presided, and others present were: Thomas Henderson, Winton; L. H. Kittredge, Peerless; C. C. Hildebrand, Stevens-Duryea; Charles Clifton, Pierce; S. T. Davis, Jr., Locomobile; Windsor T. White, White; H. O. Smith, Premier; A. L. Pope, Pope-Hartford; C. G. Stoddard, Stoddard-Dayton; J. W. Gilson, Mitchell; S. A. Miles, general manager.

A. M. C. M. A. CONSIDERS SHOW PLANS

NEW YORK, June 7—New schemes of decoration and a new arrangement to secure additional space in the tenth international automobile show, which opens in the Grand Central Palace on next New Year's Eve, were important subjects considered by the show committee of the American Motor Car Manufacturers' Association in its meeting June 3. The Importers' Automobile Salon will, as usual, occupy a portion of the main floor, and the Motor and Accessory Manufacturers will again have the 16,000 square feet of space in the first balcony. At the meeting of this committee were: R. E. Olds, Reo; H. O. Smith, Premier; Alfred Reeves, general manager.

Routine affairs were discussed at the regular monthly meeting of the committee of management, held on the same day. Those present were: H. O. Smith, chairman, Premier; C. G. Stoddard, Stoddard-Dayton; R. E. Olds, Reo; S. H. Mora, Mora; W. H. Van Der Voort, Moline; Charles Lewis, Jackson; G. V. Rogers, Mitchell, secretary, and Alfred Reeves, general manager of the A. M. C. M. A.

ELECTRIC VEHICLE CO. REORGANIZATION

HARTFORD, CONN., June 7—All doubts as to the early reorganization of the Electric Vehicle Company of this city, the manufacturer of Columbia automobiles, has been swept aside by the order of Judge Cross directing parties in interest to show why a plan made by the reorganization committee should not be accepted. This committee presented the plans before the United States Circuit Court at Elizabeth, N. J., on Thursday, outlining an offer to take over the assets of the concern, barring the cash in the hands of the receivers. Since it became insolvent on December 10, 1907, the interests have been managed by Receivers Henry W. Nuckols, of this city, and H. M. Barret, of Elizabeth. The committee is composed of Herbert Lloyd and C. W. Woodward, of Philadelphia, and K. B. Schley, of New York, and by its plan the receivers would be able to declare a 20 per cent. dividend on the unsecured claim of $800,000. The bondholders of the $2,250,000, secured by general mortgage, would waive their security and accept the same dividend. The business would be taken over by a new corporation, under the laws of the State of Connecticut.

WHY MAKERS HAVE BEEN SLOW IN ENTERING

ACCORDING to Chairman F. B. Hower, of the A. A. A. Contest Board, the prosperous condition of the automobile industry is strikingly exemplified by the letters he receives regarding entries in the A. A. A. tour and contests for the Glidden, Hower and Detroit trophies. There is a sameness to many of them this year that he never has found before, he says. The manufacturers write that they want to be in the tour, and feel that they can illy afford to stay out, but that they have not entered before because they are so far behind in deliveries and so short of cars that they cannot see a month ahead.

"It is notable as showing the interest of the manufacturers that they are writing to me to explain why they have not sent in entries," says Chairman Hower. "In former years they have not taken this trouble to write, so it is plain that they appreciate more than ever the importance of participating in this one big touring contest. One and all, however, complain of being short of cars, and so busy at the factory as to be unable to spare any men. This is a splendid condition for the trade and I rejoice in it, but I hope the present prosperity does not lead to shortsightedness. It is very well to be oversold this year, but there are other years to come. There may be a glut of cars next year and there will be need of something to help sales along. The Glidden tour always counts for the year to come, not for the current year. It is the testimony of every maker who ever has participated and made a good showing that the Glidden tour record is a wonderful help in selling cars the following year."

Molines to Be Known as "Dreadnaught Squadron"

"Dreadnaught Squadron" is the name given to the three Moline Glidden Tour entries which have been entered in the runabout class competing for the Hower trophy. W. H. VanDerVoort, president of the Moline Automobile Company, is paying unusual attention to the three Molines, which will carry the numbers 100, 101 and 102. The three cars will be painted London smoke color and the crews will wear mohair uniforms of the same color.

It will be remembered that Mr. VanDerVoort entered three Molines at the close of last year's Glidden Tour after being fully convinced that the great American touring classic was by far the best automobile road event held in this country. The three Molines were entered several months before any other entries. All three cars will be the Model K, listed at $2,500, 35-40 horsepower, equipped with Bosch magneto and having a wheelbase of 116 inches.

"It is my desire to see the largest Glidden tour this year that has ever been held," says Mr. VanDerVoort. "The entire West is very enthusiastic because it is to pass through that territory this year, and in my opinion it is this section of the country which should be developed. The Middle West is unusually prosperous this year, especially the farmers, and a very large proportion of the motor car output is being disposed of out there."

Names of Cars to Be Carried on Tour Signs

A ruling concerning the tour has just been announced which will be highly pleasing to the manufacturers who enter cars and to the people of the country traveled through. The decision has been made to have the names of the cars, as well as their numbers, on the signs they carry. Hitherto the signs on the cars had only the words "A. A. A. Tour" and the year and the entry number of the car. This has been aggravating to the spectators, as well as disappointing to the entrants. All along the route of the tour some of the residents were to be seen with clippings from newspapers that gave the numbers and names of the cars, but from those not thus provided there was a continuous cry of: "What car is that?" The fact that the make of car is the first point of interest has been deeply impressed by experience upon Chairman Hower, and therefore the signs this year will be twice as large as previously and the names of the cars will be conspicuous on them.

CALIFORNIA ENDURANCE HAS FIVE CLEAN SCORES

SAN FRANCISCO, June 7—Five of the sixteen cars which participated in the second annual endurance contest over the San Leandro course, survived the ordeal with unsmirched records. The quintette contained these cars: Velie, Autocar, Mitchell, Interstate and Acme. Another Mitchell, an E-M-F, and a Studebaker 30, were three other finishers suffering from meagre penalties.

In this contest, held under the direction of the Automobile Dealers' Association, the success of a year ago was duplicated. Of the 16 cars which started over the 54-mile circuit, with 12 laps to go in 24 hours, half were able to finish, and during the entire trip, up until the last round there were generally over a dozen competitors on the roads. Starting on Sunday afternoon, May 30, they were required to keep traveling at high speed until the same time of Monday, May 31, with but slight margins from overstepping the rigid requirements for a perfect score. The penalties of those which finished, but not with clean slates, were very low. The Mitchell had 22 points for changing a spark plug and locating a broken wire; the E-M-F 4 points for a carbureter adjustment, and the Studebaker three points for stalling the motor. The roads were such as to give the competing cars strenuous tests without breaking them to pieces, and at the conclusion of the run all competitors expressed satisfaction.

Those cars which started, with their drivers, were: Apperson, Max Rosenfeld, S. K. Crocker; Buick, C. S. Howard, W. Powers, L. Andrews; Mitchell "20," E. Martin, A. E. Hunter; E-M-F, A. Eickmeier, M. S. Harris; Winton, M. L. Owesney, G. Arbuckle; Velie, A. D. Whitehead, H. Whitehead; Studebaker "30," J. H. Eagal, R. Newcomb; Buick, F. Gross, F. Murray; Mitchell "40," J. Sexton, E. L. Peacock; Autocar "25," P. J. Brown, W. C. Morris; Auburn, F. Bryant; Durocar, J. B. Robinson, J. A. Houlihan; Speedwell, J. H. Gordan; Interstate, G. C. Murray; J. F. Burkhard; Acme, F. Free, W. H. Middleton; Studebaker "40," S. Marshall. All but one of the contestants made the first round in good time, the exception being the Durocar on which the oiler stopped working, but after being repaired the car continued and unofficially finished nine rounds. On the second lap two other machines retired: the Auburn breaking a fan, and the Studebaker "40" running dry so that penalties which accumulated made it hardly worth while to continue. The Speedwell stopped in the fourth circuit with carbureter trouble from dirty gasoline, and then for three rounds the cars all kept running well, 12 of them contestants, and during the same period the Durocar also took to the roads. In the eighth lap the Winton broke a spring but it was repaired and the machine continued until the repair also gave way in the twelfth, and forced a stop. For two more laps the class kept up the fast work and in the eleventh one Buick, which had been having trouble throughout the trip, retired. The final lap witnessed the withdrawal of two other cars, the Apperson, which had a broken gasoline feed pipe, and the Buick, which had a valve break and this tore a hole in a piston. The fastest lap was made in 1:25:34.

Those who handled the contest were: Starter, R. R. l'Hommedieu; chief scorer, G. E. Johnson; chief timer, C. Kirkpatrick; chief observer, S. D. Rogers; clerk of course, George Mountz; judges, H. M. Owens, G. T. Sterling, W. M. Klinger.

WORCESTER MAY FURNISH NATIONAL HILL

WORCESTER, MASS., June 7—Following the visit to this city of Lewis R. Speare, president of the American Automobile Association, it has developed that this city may be a scene of future national hill climbs, for a grade has been surveyed near here that surpasses anything in this part of the country. It is located on the west side of the city, and has been measured accurately, showing a straightaway length of over a mile, with a grade of 25 per cent. in some places, and a steep enough average. President Speare assured John P. Coghlin, president of the Worcester Automobile Club, that if a road is built on this hill, it will be selected as the location of the national contest.

This information has given added impetus to the enthusiasm for the hill climbing events which will be held on Saturday on the Dead Horse hill, and the entries are more numerous than was expected. The big Benz will be driven by David Bruce Brown, the Fiat by Ralph DePalma, the Knox Company has listed four entries, including its Vanderbilt cars; and Basle will handle the Renault.

The officials for the climb have been announced as follows: Referee, Lewis R. Speare, president, A. A. A.; starter, Fred. J. Wagner; clerk of course, Charles F. Webb; committee of arrangements, George D. Webb, Daniel F. Gay, Herbert P. Bagley, A. H. Inman; timers, A. H. Inman, F. L. Murdock, G. B. Cutting, J. Walter Flagg; judges, Frederick Tudor, president, and J. Fortescue, secretary, Bay State Automobile Association; A. E. Bliss, president Massachusetts State Automobile Association, Malden; John L. Heinze, president Lowell Automobile Club; A. E. Lerche, president, and Stanford L. Haynes, Springfield Automobile Club; E. P. Charlton, president Fall River Automobile Club; E. H. Walker, president Brockton Automobile Club; A. D. Converse, president Winchendon Automobile Club; Charles P. Smith, of Springfield, president, and W. H. Chase, of Fitchburg, Wachusetts Automobile Club.

CHALMERS-DETROIT PERFECT IN JERSEY RUN

In the endurance run of the New Jersey Automobile and Motor Club for amateur drivers, held May 27, W. L. Ferguson made a perfect score with his 30-horsepower Chalmers-Detroit touring car. In the report of this contest in THE AUTOMOBILE of June 3, Mr. Ferguson was erroneously stated to have withdrawn after completing one lap and to have had five punctures, when in reality he finished the first round on the dot of the minute and the second lap but five seconds ahead of time. He had no tire trouble from start to finish, and was awarded a perfect score cup by the club. Confusion of numbers resulted in crediting Mr. Ferguson's score to the Autocar, driven by M. A. Carpenter, which immediately followed the Chalmers-Detroit and which should not have been given a perfect score in the story of the event. Attention has been called to the mistake by George Paddock, president of the Paddock-Zusi Motor Car Company, the Newark agent for the Chalmers-Detroit.

CHADWICK CLIMBER WAS A STOCK CAR

Nowadays, when the public is learning to differentiate between the performances of specially constructed racing craft and the more valuable efforts of stock cars, no manufacturer can be blamed for insisting upon credit when credit is due.

This is illustrated by an objection filed by the Chadwick Engineering Works of Pottstown, Pa., which demurs against being classed at the Wilkes-Barre hill climb as having participated with other than a stock car. Its six-cylinder climber is designated positively as "stock," and considering that with only half the horsepower of the 120 Benz it required only 4 2-5 seconds more in which to make the ascent, the makers take considerable credit, especially when such a flyer as the Fiat *Cyclone* was numbered among the defeated.

In the invitation event, from which the racing Benz was barred, the Chadwick won and made the journey up Giant's Despair in one-fifth of a second better than its earlier performance.

KOKOMO CELEBRATES HAYNES ANNIVERSARY

KOKOMO, IND., June 7—In honor of the sixteenth anniversary of the completion of Elwood Haynes' first gasoline automobile, this city took a day off on Wednesday for a fitting celebration, giving the business section over to the automobilists. The streets were roped off for contests, and business men devoted their time to serving on reception and other committees, while both the Haynes and Apperson factories entered heartily into the spirit of the affair. There were visiting delegations from cities and towns within a radius of 75 miles, so that several thousand persons saw the various events, including a parade in which about 200 cars participated. A brass band on the courthouse square enlivened proceedings, and Herbert Lytle, Loring Wagoner, and other well-known drivers took part in the contests. The courthouse square was also the scene of the races and other sports, there being a slow race which was won by Murden in a Haynes in 2:55, a reverse race won by McLain in an Apperson in :40 3-4; egg race, balancing contest, potato race, and class races for autos divided by their rated horsepowers. Edgar Apperson won a race for test cars of that make, and Miss Katrina Fertig, of Indianapolis, took both contests for women, driving her Premier. Herbert Lytle in an Apperson Jack Rabbit in the speed tests made :40 1-4 seconds.

ROBERTSON, ROBERTS, HAUPT: HOUPT TEAM

NEW YORK, June 7—Herreshoff and Houpt automobiles will be entered in many important races of the season, according to the plans made by Harry S. Houpt, and in preparation he has secured one of the strongest teams of racing drivers ever assembled in this country. George Robertson, the winner of the Vanderbilt and Fairmount Park races last fall, and of other contests, is at the head of the contest department. Montague Roberts, who has been at the wheel of Thomas cars in many big speed events, is a member of the team, but it is possible that his duties in the mechanical lines of the Houpt companies will prevent him from taking as active a part as his colleagues. Willie Haupt, who distinguished himself with Chadwick racers all last season by winning every important hill climb in the East and Middle West, and by leading the Vanderbilt race last fall for four laps, has come over from Philadelphia and is becoming familiar with Herreshoff and Houpt construction. The former cars are being produced in quantities and are now in a position to enter light car races and others in class, but the big Houpt machines will hardly be ready to make their contest début until the Lowell carnival.

It is probable that still another well-known racer will be engaged to make up a quartette, but as yet negotiations with him have not been completed. Suffice it to say, that by many he is rated as one of the best racing drivers in America, and with the others equally as well considered the new team will be watched with great interest.

Willie Haupt, George Robertson, Montague Roberts

DAYTONA TO GRAND RAPIDS IN A REO

NEW YORK, June 7—There arrived in this city last evening a two-cylinder Reo roadster which has already covered 1,500 miles and has about 900 more to go in a trip from the auto-famous beach at Daytona, Fla., to the Furniture City—Grand Rapids, Mich. Owned and driven by Charles A. Luce, of the latter place, and accompanied only by Mrs. Luce, the little car has had a strenuous mud-plugging tour, especially after reaching the sand and clay of the lower Carolinas, and has been on the go for 22 days, not including 10 which were taken off for rest or because of the heavy rains of late. Mr. and Mrs. Luce left the Southern resort on May 4, and will leave to-morrow on their way to their home via Buffalo and Cleveland. In speaking of the trp to date, Mr. Luce said:

"We have had a hard tour on account of the weather and road conditions, and because it has been necessary often to make short runs because we had to calculate upon our night stops. Frequently if we pushed beyond one small town in the South we would not reach another for many miles. Our route has taken us through Jacksonville, Lake City, Jasper, Valdosta, Macon, Atlanta, Salisbury, Greenville, Winston-Salem, Danville, Chatham, Staunton, Hagerstown, York, and Philadelphia. We have found every imaginable kind of road, mostly bad, but they will be improved shortly, for the people of the South have been stirred up beyond the Northern comprehension by the present movement. We ran from Atlanta to Greenville with the White scout car sent out by the Atlanta *Journal*, and we met R. H. Johnston in the New York *Herald* White scout car at Roanoke. The roads of the Carolinas, and of Georgia also, are nearly bottomless in wet weather, and I have found a route between Danville, Va., and Roanoke, via Chatham, that is far superior to the usual course via Lynchburg. My car was the first automobile over it.

"From Salisbury to Philadelphia we had a continual mud-plug, with only three sunny days, and of all the roads the pikes around Staunton were the hardest to travel because of the broken stone set on edge. Our tires were nearly worn through by them. I cannot say too much of the Reo, for it has made the run in wonderful shape, especially upon the hills and on muddy roads. From Salisbury to Roanoke we had to use low gear most of the time, but that had no effect upon the working of the car. Our route to Cleveland will be that generally taken by autos and we have not decided just when we will try to reach there, as we take the trip by easy stages, the best way for any persons on a long tour."

TRAVELS 134.3 MILES ON ONE CHARGE

PHILADELPHIA, June 7—The Woods electric victoria which made such a creditable record in the recent roadability run of the Quaker City Motor Club to Atlantic City, covering the 67-mile route in 4:35:40 on one charge, eclipsed that performance last Tuesday, when it negotiated the round trip of 134.3 miles on one charge of "juice." Driver George W. Daley, who swears to the correctness of the statement, makes further affidavit to the effect that after completing the homeward journey, the car was run until the odometer showed 152 miles, before the batteries were exhausted.

The actual running time to Atlantic City was 3 hours and 45 minutes, or 16.2 miles an hour. The return trip began at 4:18 P. M. and the electric drew up at the starting point, in front of the *Record* office, at 9 o'clock exactly.

On Thursday Mr. Daley gave the electric another try-out, this time for speed. A roundabout route of 89.2 miles was selected, and the car reached Atlantic City in a trifle over five hours, the average figuring out at 17.6 miles an hour. The odometer showed 104.2 miles before recharging was begun.

Marshalltown, Iowa—The Johnston Automobile Company has let the contract for the erection of a new garage, to be built of brick and cement, on East Lincoln street.

Cars That Carried Troy's Orphans at Van Rensselaer Park

TROY CLUB FETES THOUSAND CHILDREN

TROY, N. Y., June 7—Fully 1,000 orphans from the various institutions of this city were given an outing by the Troy Automobile Club on Wednesday. The members of the club contributed 130 touring cars for the purpose, and the little folk were taken to the local "Coney Island," after a ride of about 12 miles, where they were the guests of the club and management. Two hours were allowed for sight seeing and the enjoyment of the games, and then they were returned to the different homes in the autos, tired and happy. During the outward-bound parade every church bell in the city was rung and large crowds greeted the procession along the line of march.

DETROIT GAVE ORPHANS A GRAND TIME

DETROIT, June 7—Six hundred Detroit orphans were given the time of their lives last Friday as guests of the Detroit Automobile Dealers' Association and the Detroit Automobile Club. One hundred machines were furnished for the occasion. Frank Weldon, who officiated as master of ceremonies, provided each youngster with a small American flag, and as the procession sped along it resembled one grand stream of Stars and Stripes. No charitable institution in the city was overlooked. The only feature marring the festivities was the fact that one hundred children at the Home for the Friendless were unable to participate in the outing, the institution being quarantined because of diphtheria.

The orphans were given a ride about the city, over Belle Isle, with a visit to the "zoo"; out to Grosse Pointe and back—in all, about forty miles were covered.

At the conclusion of the run the older children were taken to the Pontchartrain and treated to light refreshments, bringing to a close the most successful event of its kind ever undertaken and giving to 600 orphans a day's pleasure they will long remember.

LONG AUTO RIDES FOR PITTSBURGH ORPHANS

PITTSBURGH, PA., June 7—An extended automobile ride was the important feature of the celebration of orphans' day in this city, in addition to the visit to the "Zoo" and a luncheon, under the direction of the Automobile Club of Pittsburgh. Friday was selected for the day, and almost 700 children were given a treat, beginning at 10.30 A.M., when the automobiles brought the little folk from the various institutions to Craig street, just off the Grant boulevard. A parade was formed and the cars run to Highland Park, where are located the wonders of the big zoölogical gardens. The cars then went over every bit of boulevard in the East End and landed their loads in Schenley Park at about 1 o'clock for a fine luncheon, which was served just beyond the Panther Hollow bridge, one of the most beautiful spots around the Smoky City. The parade began again after lunch, covering many more miles of boulevards, breaking up and leaving the children at their homes about 4.30 P.M. The committee in charge consisted of: Paul C. Wolff, secretary of the club; A. E. Nenan, J. N. Hawkins, E. J. Kent and Edward Kneeland.

WHAT WILL NEXT COME FORTH?

With the completion of arrangements for the sale of the whole of the product of this season, a number of the largest manufacturers are announcing the details of their models for the season which will follow. Many others who have not gone to this length have given out an idea of the principal features of the cars to which they will devote their energies, and of a third class, rumor only has spoken as to the product.

Thus it is that plans are made public, and among these plans are many which will interest the people; some for the folks able to buy luxurious cars, on which the improvements take the form of added luxuries, others (and these will be most numerous) will appeal to the great class of people who up to date have been nothing but "wishers" because of the prevailing prices.

It is to the latter class, only able to pay a very small price as prices go, but numerous in the extreme, that a few manufacturers will cater for the first time. These cars will be the very personification of simplicity, both as to number of parts and their functions, resulting in a simple and easily mastered control system. Many, if rumor is trustworthy, will be equipped with two-cycle engines, several of the differential piston type. But this seems like a case of saving at the bung-hole to waste at the spigot, for the fuel consumption of this type of motive power is notoriously high. Of what avail is a poor man's automobile at $1,000, if the fuel and upkeep cost is equal to that of a $4,000 machine?

Actually the increased upkeep cost would be a greater hardship than the greater initial expense, for the latter comes but once, while the former partakes of the nature of a continuous performance, which must go on as long as the machine is employed, and is only terminated when it is disposed of and the pleasure of use ceases.

One prominent development will be the absence of freaks in the class known as "best sellers," most of which will continue the present types without change. In this category come the six-cylinder motors for high powers, all of which will doubtless be continued as at present.

In the list of mechanical features worthy of mention, it is noticeable that the fuel question is being given increasing thought, and the 1910 cars will include many which are fitted for the use of a fuel other than gasoline, and still more arranged for fuel injection. An observed trend is in the ignition, single ignition with a magneto as a source of current being on the gain at the expense of other forms. Many of the very low priced cars will doubtless turn to the two-speed transmission, while there will still be many who adhere to the planetary type, with its inherently simple control.

Equally as conspicious as the newer features or the changes in the product of the high class producers will be the new faces in the industry, these being recruited chiefly from the implement, agricultural, and buggy manufacturers of the Middle Western States.

All told, the season of 1910 will make many remarkable changes in the industry as a whole, and much will be added to automobile history.

* * *

IN THE TRAIL OF THE BIG TOUR

Possessing roads that were such in reality, the more populous East naturally adopted the automobile with greater alacrity than the more sparsely settled West with its widely separated cities and lack of highways worth mentioning. Hence the annual national endurance tour generally had either its beginning or its finish, or both, in the Atlantic and Middle States.

But this year there is a plunge to the Northwest, and thence down into the Rocky Mountains country. The route traversed is a comprehensive one for the middle part of the country, and furthermore, direct attention to the automobile will be carried to thousands of people who are yet comparatively strangers to its pleasurable and time-saving necessities.

It would appear that those manufacturers who participate in this year's big tour are certain to realize substantially in one form or another, even though it is a certainty that under the rules laid down there cannot be any considerable number of tied trophy winners. The rules-making committee has been conscientiously at work for the past fortnight, and the results of its labor should prove uniformly acceptable.

Of course, the roads to be encountered will comprise good, indifferent, and bad, but not to such an extent as is imagined by the self-satisfied Easterner who deludes himself in the belief that nothing West of Buffalo, or Chicago at the extreme limit, is worth while in this big country. Many an automobile opinion will be revised in the trail of the 1909 Glidden tour.

DECISION IN SELDEN SUIT EXPECTED IN FALL

JUDGE HOUGH of the United States Circuit Court, Southern District of New York, has been well supplied with reading matter for his Summer vacation. Some 10,000 printed pages of testimony, including briefs filed by both sides, of some 1,700 pages, are now in his possession as a result of the hearing which closed Friday, June 4, after having continued for six days.

In view of the grasp of the situation which Judge Hough demonstrated during the hearing held in the Post Office Building, New York City, it is generally expected that a decision may be announced in the Fall.

The hearing was on a consolidation of a number of suits, in all of which the complainants were the Electric Vehicle Company and George B. Selden. The several defendants were C. A. Duerr & Company and the Ford Motor Co.; in another suit the O. J. Gude Co., and in another John Wanamaker. Coupled with these actions was the suit against Panhard & Levassor and Andre Massanet, its agent, as well as one against Henry and A. C. Newbauer, importers of automobiles.

Samuel R. Betts, of Betts, Sheffield, Bentley & Betts, opened for the complainant, and was followed by R. A. Parker, of Parker & Burton, who argued for the defendants, and particularly represented the suits directed against the Ford company and its agents. The defendants' argument was then taken up by John P. Murray, of Coudert Bros., more particularly representing the foreign manufacturers. William A. Redding, of Redding, Greely & Austin, then took up the rebuttal argument for the complainants, after which W. Benton Crisp continued the argument for the defendants, and Frederick Coudert closed for them. The closing argument for the complainants was made by Frederick P. Fish, Esq., of Boston.

When asked as to his opinion regarding the hearing, Hermann F. Cuntz stated specifically that he must refrain from expressing any views whatsoever. He explained that the case was now before the court, all the briefs had been submitted and the entire record that has been printed containing testimony taken in the past five years has been filed with the court, and hence it would be obviously improper in any way to forecast any opinion.

R. A. Parker gave his views of the matter as follows:

"It would not be proper for me to give my opinion as to which way I think that the Selden suit will be settled, as long as it is now in the hands of the court. Suffice it to say that I feel confident, as do my clients. It is probable that the decision will be rendered in the Fall, or perhaps later, because there is a mass of testimony to be considered. Our claims are too well known to need discussion, inasmuch as in the suit and the argument last week there was little dispute as to facts. We believe that the plaintiffs cannot hold a patent such as will prevent any man from using any liquid hydro-carbon engine in any road carriage, and because of it sue anyone who does. The patent could apply only to some absolutely new way of combining a certain motor with a certain road carriage, and the independent makers have not done this, and therefore are not bound by the patent to pay the royalties which are claimed. Thus I took the position that a motor which is capable of being applied, when combined with a road carriage capable of being driven by one or more of many motors, cannot be patented. That would simply be a patent of an old use, even if the motor is new, as long as it is a motor. Another point which we brought out was that Selden changed his claims after the Benz patents were taken out in this country in 1888, for although the Selden patent had been applied for first in 1879, the claims were changed in 1889 and the patent was not issued until 1895, so that during a period of years the patentee was benefiting by the experiments of others. Therefore we claim that he has not a right to a universal patent covering the subject, according to decisions of the Supreme Court.

"As to the probable developments after the decision, it may be stated positively that if the patent is upheld, we will appeal, and if the patent is not upheld, the plaintiffs are compelled to appeal by the contract between the A. L. A. M. and the other Selden interests. The only way this could be avoided by them would be to make a new contract and let the matter drop. At any rate if an appeal is taken it would not get into the next court until probably a year from next October, and it would take perhaps six months in the Court of Appeals, so that perhaps it would be two years from the present before another argument would be held, and it can be seen that the patent will nearly have expired, in 1912, before the case would be settled. Should it become necessary it might even be carried to the Supreme Court.

"This brings up another interesting point as to what may develop if the patent expires before the final settlement. If the present defendants, the independent manufacturers and importers, should finally win, the case would be dropped; but if the licensees should win, the question of damages would be a very important matter. It is my opinion that they would have great difficulty in trying to collect. Therefore I feel very confident as to the outcome, both in the near future and that farther away."

MACALMAN PRESIDENT BOSTON TRADE

BOSTON, June 7—The annual meeting of the Boston Automobile Dealers' Association was held to-day and the following officers were elected for the ensuing year: President, J. H. MacAlman, agent for the Columbia and Stearns; vice-president, J. S. Hathaway, manager of the White Company branch; treasurer, F. A. Hinchcliffe, manager of the Winton Motor Carriage Company branch; secretary, Chester I. Campbell; directors, the officers, and J. W. Maguire, agent for the Pierce; Charles E. Fay, manager of the Ford Motor Company branch; A. P. Underhil, agent for the Knox; C. F. Whitney, agent for the Alco and Stoddard-Dayton; E. A. Gilmore, of the Whitten-Gilmore Co., agent for the Thomas, Chalmers and Hudson, and Frank E. Wing, agent for the Marmon. Mr. Wink succeeds George H. Lowe, resigned, otherwise the organization is the same as previously.

RAIN POSTPONES CLEVELAND'S CLIMB

CLEVELAND, June 7—Rain coming up late Friday spoiled the roads for the annual Porter hill climb of the Cleveland Automobile Club. The climb will take place Wednesday, June 9.

S. A. E. HAS BEEN INCORPORTED

In order to carry out rather extensive plans for the future, the Society of Automobile Engineers has been incorporated, the papers having been approved in New York City Tuesday, by Supreme Court Justice Guy.

There will be twelve directors and the principal office will be in New York City. The incorporators named are as follows: Russell Huff, of the Packard Motor Company, of Detroit, Mich.; Andrew L. Riker, of the Locomobile Company, Bridgeport, Conn.; Henri C. Chatau, of the General Electric Company, Schenectady, N. Y.; B. D. Gray, of the American Locomotive Works, Providence, R. I.; R. C. Carpenter, of Sibley College, Cornell University, Ithaca, N. Y.: Henry Hess, of Philadelphia: F. J. Newman, of Chicago: Alexander Churchward, of 2 Rector street: Horace M. Swetland, and Thomas J. Fay, of 239 West Thirty-ninth street, New York City. The summer meeting of the society may take place in Chicago, probably in August.

Tungsten Lamps for Auto's Use—Miniature sizes of tungsten lamps can now be obtained for use on automobiles in the place of oil side lamps using kerosene, or for use in enclosed cars.

Temporary Road Repairs

IT is almost impossible to overestimate the enthusiasm for good roads which has been stirred up in the Southern States through the movement started by the New York *Herald* and Atlanta *Journal*. It was my good fortune to be selected to drive my White Steamer as the New York *Herald* "scout car" from New York to Atlanta. Never before in my touring experience have I seen such an ovation as greeted our party throughout our 1,100-mile journey, commencing from the moment when we were started on our journey from Herald Square by General Leonard Wood to the time when we were met on the outskirts of Atlanta by ex-Governor Hoke Smith, of Georgia, Mayor Maddox, of Atlanta, and several hundred of the leading citizens of the empire city of the South. During at least two-thirds of our journey, we were escorted by a convoy of from one to a dozen automobiles which came to meet us from various towns along the route. The garages where we stored our car over night refused to take payment for gasoline and other supplies and when we came to pay our hotel bills in the morning we found that we had been anticipated by the local chambers of commerce.

It would be too much to say that the sentiment for good roads was created over night by the enterprise of the two newspapers mentioned above. Undoubtedly the sentiment for good roads already existed, but it needed some concrete enterprise, such as a proposition to build a great highway between New York and Atlanta, to crystallize the good roads sentiment and to bring together in co-operation the various automobile clubs along the route, the principal civic bodies in the various cities, and the farmers' organizations in the rural districts. If one-half of the proposed bond issues which we heard about materialize, there will be more money spent on the roads between New York and Atlanta in the next six months than has been spent in the last six years. In the office of the Atlanta *Journal* I looked over several hundred newspaper clippings relating to good roads. Apparently, there is hardly a newspaper published between New York and Atlanta, either in a large city or in a rural community, which has not undertaken to agitate the good roads question in its editorial columns. It is my judgment that within two years the tourist may go from New York to Atlanta without any more fear of encountering severe road conditions than if he were to start for a tour through the New England States.

The route which we covered on our recent tour is one of two or three possible routes between New York and Atlanta. It is by no means the shortest route, but at the present time it is probably the best. The fact that we made the 1,125-mile trip in eleven days, despite the necessary stops for compiling road directions, for taking photographs, and for the receptions along the line, will indicate to every autoist that the route is a thoroughly feasible one, even in the present state of road conditions.

The route which we followed was as follows: southward to Philadelphia and then westward to Gettysburg; then southward again through the Shenandoah Valley to Roanoke, Virginia, then eastward to Danville. From that point we followed approximately the main line of the Southern Railroad through the prosperous regions of the New South all the way to Atlanta.

Considering our route from New York to Atlanta more in detail, the road from New York to Trenton is so well known as to need no comment. Going south from Trenton, most tourists go by way of Bordentown and Camden, but we took a shorter route by crossing the Delaware River by the Trenton bridge into Pennsylvania, and thus avoided the ferry at Camden and the narrow east-and-west streets of Philadelphia.

For 25 miles west of Philadelphia the road is perfect, yet it would seem that the time has come to eliminate the toll gates from the main highway leading westward from the third largest city in the country. After leaving the toll road, we found the road through Coatesville and Kinzer rather rough, but it improves again near Lancaster when we made good time through Wrightsville and York to Abbottstown. From there to Gettysburg, a distance of 15 miles, the road is very rough.

On the Battlefield of Gettysburg the roads were built and are maintained by the National Government, and, needless to say, are in perfect condition, just as they are on Missionary Ridge and the other national reservations where the nation has undertaken road building.

On leaving Gettysburg, on the morning of the third day of our trip, we had rather rough going for ten or fifteen miles, and then we came to a good macadam road which led us through Waynesboro, Hagerstown and Shepardstown to Winchester, Virginia, where we came to the famous Shenandoah Valley pike, over which we traveled another 95 miles to Staunton. Over more than two-thirds of the distance from Gettysburg to Staunton we paid toll at the rate of from three to five cents a mile.

Our run from Staunton to Roanoke, a distance of 93 miles, was made under very severe conditions. The roads had just been ploughed and were drying up from a hard rain of two days before. The soil was of a consistency which allowed the wheels of the car to sink in nearly to their hubs, and it was just stiff enough to make very hard pulling. Added to this, the going was mainly up hill, with the result that it took much more power to negotiate these roads than was necessary on any other part of the journey.

From Roanoke to Danville we had what could be called fair dirt roads, and this stretch of 117 miles should offer no particular difficulties. The same may be said of the stretch between Danville and the State line between Virginia and North Carolina. It must be understood, however, that the roads in Virginia south of Staunton were not laid out with reference to the requirements of automobile traffic.

The North Carolina roads, almost without exception, are good. Those in Mecklenburg and Gaston counties, particularly, are all that the tourist could wish for as regards smoothness, gradients, drainage, gradual turns and proper banking at the turns.

As for the roads of South Carolina and Georgia, I would say from my observation on this tour and on previous tours through this section, that they are good in dry weather and bad in wet weather. What the tourist wants, however, and what I am convinced will be obtained through the good roads movement started by the New York *Herald* and the Atlanta *Journal*, are roads that will be good in any kind of weather.

As regards the time for the average tourist to make the trip from New York to Atlanta, here again much depends upon the weather. In good weather, on a "keep-going" schedule, eight days should be sufficient time. In rainy weather it is probable that at least two weeks would be necessary. If the tourist should plan to see thoroughly all the places of historic interest and of great natural beauty along the route and, particularly, if he should accept all the invitations which are showered upon him by the hospitable people of the South, an entire touring season would be none too much to allow for the journey.

ALL WANT TO BE ON NEW YORK-ATLANTA ROUT

In the wake of the proposal to build a national automobile highway between New York and Atlanta came the rivalries of the cities and towns on the several proposed routes.

Leonard Tufts, a Bostonian well known in the development of Pinehurst, N. C., supplied excellent reasons for the route across North Carolina which would include Pinehurst and Southern Pines. From material Mr. Tufts sent out is the following:

G. N. McMillan has been a guest at Pinehurst for several years, and through his enthusiasm and interest in the subject he with others induced the people of Southern Pines and myself to build a road between Pinehurst and Southern Pines. This was the first really good road in the southern section of Moore County. Since then four townships have voted to tax themselves for good roads, and one has recently got a bond issue for $15,000. Mr. McMillan has been pushing and talking good roads for the past three years and has believed from the first that a highway from the North to the South would be made practical within a few years with proper organization and push. At first this seemed absurd to me and to others, but I believe his prophecy will come true during the coming winter. Captain W. I. Everett, of Rockingham, N. C., has been a great power in interesting people in Richmond County in building roads. There are a great many people, as for example, Dr. Gilbert McLeod, of Carthage, who has given his time for the maintenance of the roads; John R. McQueen, of Lakeview, who is responsible for the bond issue of McNeil Township. The result of this work is that this fall there will be a fine road across Moore and Richmond counties going by way of Vass to Lakeview, Southern Pines, Pinehurst, West End, Jackson Springs, Elba Springs and Rockingham, toward Cheraw to the South Carolina line.

Crown Point, Where the Storm Centre of the Contests Will Be

CHICAGO, June 8—Thirty entries—12 in the Cobe cup and 18 in the Indiana trophy—have been received for the road-racing carnival of the Chicago Automobile Club, set for decision June 18 and 19 over the Crown Point-Lowell course, the list officially closing Saturday at the regular fees, although it is possible for others to get in up to Thursday of this week upon payment of an extra charge of $250 a car. In point of numbers this compares most favorably with Savannah, which has the record with 37 entries.

Thirteen different makes of cars are represented in the two races, six being in the Cobe cup. In addition the Locomobile, Stoddard-Dayton and Buick are in both contests. The entry fees total $10,700. Drivers nominated include such stars as Robertson, Lytle, Strang, Florida, Poole, Denison and Bourque, the complete entry list reading as follows:

COBE CUP

Car	Driver
Apperson	H. Lytle
Apperson	Not named
Buick	L. Strang
Buick	R. Burman
Buick	L. Chevrolet
Fiat	E. A. Hearne
Knox	A. Denison
Knox	W. Bourque
Locomobile	G. Robertson
Locomobile	J. Florida
Stoddard-Dayton	C. A. Engubeck
Stoddard-Dayton	B. Miller

INDIANA TROPHY

Buick	L. Strang
Buick	R. Burman
Buick	G. DeWitt
Chalmers-Detroit	A. Poole
Chalmers-Detroit	J. Matson
Chalmers-Detroit	W. Knipper
Corbin	Not named
Fal-Car	E. M. Harrison
Fal-Car	A. H. Peirce
Ford	Not named
Locomobile	G. Robertson
Locomobile	J. W. Florida
Marion	H. E. Stutz
Marion	A. Monsen
Moon	P. Wells
Renault	A. W. Greiner
Stoddard-Dayton	H. Tuttle
Stoddard-Dayton	Not named

With the entry proposition off their minds the promoters of the contests are now busily engaged in completing the arrangements at Crown Point. The course is rapidly nearing completion, and it is expected the contractors easily will finish by the stipulated time—to-morrow. The entire circuit has been treated with taroid, and while there has been no attempt at speed, it is more than apparent that the course is lightning fast. Indeed, there is hardly a driver who has seen it who has not predicted a smashing of records in both events. Considerable difficulty has been experienced by motorists gettting on the course just for the purpose of trying it. Generally the result has been that they have had their cars plastered with tar, while the ravages of their wheels have compelled the road-makers to do additional work.

The big grandstand, which is designed to hold 10,000 people, is as good as done, although the contractors still have several days more in which to put on the finishing touches. The sale of seats for this stand is up to expectations, although the demand so far has been more for boxes and parking spaces. Only 30 of the 164 boxes remain, while the club has been forced to secure additional parking space. But from the inquiries the grandstand seat sale will open up before the end of the week, so that everything should be sold two days before the races.

General Executive Trego intends moving his effects to Crown Point on Thursday and establishing his quarters there. On that day the official drawing for numbers will take place, while practice on the course will not begin until next Monday because of the objection of the Lake county farmers, who did not wish to have their roads tied up for 10 days as was at first contemplated. The training will take place between 2 and 4 o'clock in the afternoon because of the fact that the farmers have to use the roads in the morning to make milk deliveries.

Noted Drivers Prepare for Great Contest

Already there is a gathering of the clans. Robertson and Florida, with their mechanics, Campbell and Ethridge, are here, and the Locomobile camp at Crown Point will be established to-night. week, few suspecting that the Detroiters were there. George Bill is in charge of the camp and he has with him five men and four cars. The third Chalmers entry was not made until the final moment, at which time the company announced that its drivers will be Al Poole, William Knipper and Joe Matson. Poole, everybody knows, formerly was Tracy's mechanic, and last year he drove the Isotta in several road races. Knipper has just finished the Denver-City of Mexico stunt and is hurrying home for the new venture, while Matson gained fame as the driver of the Corbin last year.

The two Fal-Cars are making their début in competition and the Chicago concern manufacturing them has been pushed to the limit to get them out in time. This delayed the entry to the final moment, when Sales Manager Averill turned in the check.

The Chicago Automobile Club is determined to make both races stock propositions, and to insure this the members of the technical committee already have started their work visiting the various factories. F. E. Edwards went to Flint and Detroit Saturday, while Berne Nadall swung into Indiana and Ohio last night. Chairman Beecroft goes East to-night. At each factory duplicate cars are examined and measured and before any one is allowed to start there will be another examination to see if the two sets of figures agree.

TABLE SHOWING GENERAL SPECIFICATIONS OF CARS ENTERED FOR THE CONTEST FOR THE COBE TROPHY

CAR	Entrant	Driver	No. of Cyls.	Cylinder Bore	Cylinder Stroke	Wheelbase	Clutch	Trans.	Speeds	Reverse	Drive	Cooling	Oiling	Ignition
KNOX	Knox Auto Co.	Denison	4	5	4.75	106	Three-plate	Sel.	3	1	Shaft.	Gear pump	Gear pump.	Dual.

OCEAN TO OCEAN RACERS IN THE OPEN WEST

ST. LOUIS, June 7—Much like four spirited animals which have been held in leash and then suddenly turned loose, the quartette of autos which are racing from New York to Seattle left this city this evening, free to go as far and fast as they choose. Leaving New York on last Tuesday afternoon, they were kept well bunched by Pacemaker Gerrie until this city was reached, when the restrictions were removed, and at 8.15 o'clock this evening the two little Fords, which have been in the lead, swung out into the open country toward Kansas City, with the big Acme and the Shawmut not very long behind them.

NEW YORK ORPHANS' DAY POSTPONED

NEW YORK, June 9—Owing to rain the orphans' day celebration planned for to-day has been postponed until Friday. For the first time in five years, since the first outing given to the inmates of the city institutions, there has been enough cars offered, besides contributions of nearly $1,000 in cash for hiring machines. Between 150 and 200 automobiles were promised, and the donors have been requested to give the use of them on Friday. The capacity of these cars would be 2,000 children. The main portion of the day will be spent at Coney Island.

Tuesday the Long Island Automobile Club gave the orphans of Brooklyn their annual treat. Some 150 autos conveyed 900 children to Luna Park at Coney Island, which event was followed by a ride around the city. President Frank G. Webb, and Dr. W. P. Richardson, chairman of the committee, directed.

FORBES WINS BALLOON CHAMPIONSHIP

INDIANAPOLIS, IND., June 9—The balloon *New York*, with A. Holland Forbes as the pilot, is the winner of the national balloon race with a journey of 358 miles. The *University City*, Captain Berry as pilot, was second with 329 miles; the *St. Louis*, Lambert at pilot, third with 321 miles; the *Indiana*, Fisher as pilot, fourth with 264 miles, and the *Hoosier*, Captain P. S. Baldwin pilot, fifth with 234 miles. Captain Baldwin was the constructor of the winning *New York*. The handicap race was won by the *Indianapolis*, D. G. Link pilot, with 222 miles.

MANY ENTRIES FOR CATSKILL-BERKSHIRE RUN

NEW YORK, June 7—So far-famed is the touring ground of the Catskill Mountains and the Berkshire Hills, over which the New York Automobile Trade Association will hold its reliability contest next Saturday, Sunday and Monday, that there will probably be at least 35 cars in the party. They will leave Columbus Circle at 8 o'clock on Saturday morning, taking the Forty-second street ferry and reconvening on the Hudson County boulevard at Weehawken. The first night stop will be at Catskill, running via Suffern, Lake View hotel for lunch, Newburg and Kingston. The route on Sunday will be to Pittsfield, via Albany, and only the afternoon will be used in making the trip so that the participants may tour to Catskill Mountain resorts in the morning. On Monday they will return to New York via Stockbridge, Great Barrington and Poughkeepsie.

The cars which have been entered so far are: three Mitchells, three Franklins, three Stevens-Duryeas, two Stoddard-Daytons, two Oldsmobiles, two Marmons; one each of National, Lancia, White, Knox, Royal Blue cab, Packard, Autocar and Matheson.

MITCHELL AGNETS HAVE CONCLAVE

NEW YORK, June 7—To discuss the output of the Mitchell Motor Car Company for the next season, and to give the management a better idea of what the public wants, as seen through its local representatives, 25 of its agents held their annual convention in the Manhattan Hotel last week.

The following were in attendance: From the factory, William Mitchell Lewis, general manager; J. W. Bate, designer; James W. Gilson, sales manager; G. V. Rogers, secretary; George W. Osen, San Francisco; E. E. Gilmore, Jacksonville, Fla.; Fred Bennett, Portland, Ore.; J. Clarke Coit, Omaha, Neb.; E. H. Greer, Los Angeles, Cal.; C. F. Gilmore, Detroit; A. F. Chase, Minneapolis; W. W. Sears, Des Moines, Ia.; Nelson T. Hayes, Kansas City, Mo.; George Weber, St. Louis; Horatio L. Hall, Chicago; W. M. Jenkins, Boston; J. A. Cramer, Buffalo, N. Y.; John Van Benschoten, Poughkeepsie, N. Y.; J. M. Cram, Racine, Wis.; Walter M. Cram, Philadelphia; F. L. C. Martin, Plainfield, N. J.; Charles P. Skinner, Warren D. Brown, O. R. DeLamater, George A. Skinner, New York.

Packard Three-Ton Trucks as Sightseeing Buses

Several buses, each accommodating thirty-four persons have been fitted up from regular Packard three-ton truck chassis. Among the places where these will be tried are the Alaska-Yukon-Pacific Exposition in Seattle and private enterprises at Colorado Springs, Col.

Hoblitt to Start Long Trip in Alco—F. M. Hoblitt, known generally throughout the automobile trade as the first traveling man selling motor cars, is to start June 10 on a more novel trip than usual. A couple of years ago, Mr. Hoblitt and Arthur Jervis became known as the "vanadium twins" while exploiting a new six-cylinder car of the American Locomotive Company across the country. Mr. Hoblitt is the traveling representative of the Alco pleasure cars, cabs and trucks. and on his forthcoming trip he will use a 40-horsepower Alco car instead of traveling by train. He will take no chauffeur, but will drive the car himself and carry only one passenger. Mr. Hoblitt's route includes Albany, Buffalo, Cleveland, Toledo, Chicago, Milwaukee, Minneapolis, Denver, Kansas City, St. Louis, Louisville, Columbus, Pittsburg, Philadelphia and New York. This means that he will cover the full route of the Glidden tour as an incidental part of his trip, which completed, will be more than twice the mileage of the Glidden tour.

Whiskey vs. Gasoline—How whiskey, as a substitute for automobile fuel, saved a Japanese nobleman from missing a transcontinental train down in Texas, is the subject of a laughable story in the current issue of the Rambler Magazine, a publication issued in the interest of Rambler owners, by Thomas B. Jeffery & Company. A cartoon showing the progress of the automobile among the farmers of the Southwest is described in an interesting way by Mr. Jeffery, who discovered at the Kansas City automobile show that the Southwest farmer had become so prosperous that he frequently came to town to have his nails manicured. Mr. Jeffery also tells why the farmer is so prosperous, saying, "Wheat in Kansas at $1.30 costs 30 cents to raise, and corn at 75 cents costs 25 cents to raise." This is why the farmers are buying automobiles. Even the manicure lady is pictured in a comic cartoon.

Pacific Coast Wants Enclosed Cars—Within a year or two the Pacific coast will have as many enclosed automobiles as the East, is the prediction of the Pierce-Arrow western dealers who have been at the factory lately. One gave his reasons for this belief thus: "The people on the coast adopted the touring car quickly, and have realized that with the automobile a suburban home is possible, and as accessible as a town house. This has brought into use the enclosed car so that it is serviceable in all kinds of weather, and during the past year we have sold a number of 36-horsepower Pierce-Arrow landaulets and broughams. The use of the lower-powered cars of the enclosed type is bound to bring about a demand for high-powered cars with enclosed bodies. This has been shown conclusively by the inquiries made before I started for Buffalo concerning fall deliveries."

Lots of Business in Syracuse—Due to the rush of orders for light delivery trucks, the Chase Motor Truck Company, Syracuse, N. Y., has been obliged to operate its plant overtime. The factory comprises 62,000 square feet of floor space, to which has just been added two new buildings each 85 by 30 and two stories high. Moreover, even this is not sufficient, and arrangements are now being made for another building of equal size. The most recent addition to the Chase line is a business man's surrey, the construction of which is similar to other Chase cars.

Rambler Revives Road Sign Campaign—With a new issue of 5,000 metal signs for posting at doubtful points on roads, Thomas B. Jeffery & Company have revived a campaign which was started two years ago. At that time a large number of these guides were supplied to automobile clubs or to Rambler dealers throughout the middle West and in some parts of the East, and erected in needed places. The signs are 12 by 24 inches in size, ample to be seen readily, and with the production of the new ones a great many more roads throughout the country will be well marked.

New Departure Bearings on A-K Winner—The New Departure Manufacturing Company, of Bristol, Conn., is calling attention to the victory of the Allen-Kingston car in the Sport Hill climb at Bridgeport, in which car New Departure bearings are used throughout. There are four on the crank shaft, and in this contest demonstrated their workings, which combine thrust with radial load bearings. The A-K covered the distance in its class in 1:18 3-5, and the thrust stresses were severe at certain points along the course.

Continental Increases Factory Space—By the addition of a third floor to its main factory in Muskegon, Mich., the Continental Motor Company will greatly increase its facilities. For several months it has been having difficulty in keeping pace with its orders, although employing 500 men. The erection of the third story will permit the use of 200 more men and will enlarge the output materially. The company claims that it has turned down more orders for the coming year than it has accepted.

Hercules Electric Company Enlarges Plant—Sales of the new magnetos made by the Hercules Electric Company, Indianapolis, Ind., have been increasing so rapidly that greater facilities for their manufacture have become necessary. An additional building has already been constructed, with machine equipment that will increase the capacity of the concern by 50 per cent. Preparations are now being made for the erection of another plant in which the magnets will be made.

Cleveland Concern Gets New Lease of Life—A new company just incorporated has taken over the plant of the old French-American Motor Car Company, Cleveland, O. By a strange coincidence the new concern will be known as the White Motor Car Company, after the backer, W. B. White, who is, however, no relation to and has no connection with the White family in the White Company, makers of White steamers, located in the same city.

Morgan Leases Building for Worcester Factory—For the manufacturing of automobile trucks, the R. L. Morgan Company, Inc., has leased a three-story building on Cambridge street, Worcester, Mass. The structure is owned by the Crompton Associates, and formerly occupied by the Crompton-Thayer Loom Works. Between 50 and 60 men will be employed shortly, and the plant will have a capacity of 500 cars yearly.

Winton Chauffeurs' Contest Nears End—The Winton Motor Carriage Company, of Cleveland, is receiving records from all parts of the country of chauffeurs who are preparing their reports for the Winton chauffeurs' contest. The month of June is the last for the 1909 season, and already some of the outlines received have been further wonderful evidence of the satisfaction being secured from the Winton product.

Motor Car Equipment Company Leases Building—The entire building at 55 Warren street, New York, has been secured by the Motor Car Equipment Company, of 1727 Broadway, importers and manufacturers of automobile accessories. The additional space will be utilized for the large stock of materials and sundries used in filling the concern's trade saying of "Everything for the autoist but the auto."

Rapid, Too, Needs More Space—After having just completed and occupied the latest addition with a full line of automatic machinery, the Rapid Motor Vehicle Company, Pontiac, Mich., has already found the new quarters too small and has planned a concrete, steel and glass building which will be two stories high, with 76,800 square feet of floor space, the dimensions being 60 by 640.

New Company Proposed in Springfield, Ill.—Plans have been made in Springfield, Ill., for the organization of a new automobile corporation, to be called the Springfield Motor Car Company, with a capitalization of $250,000. It is proposed to erect a modern building in Harvard park, 250 by 500 feet in size, and have it ready for occupancy by fall.

Additional Factory for Salisbury Wheel Company—The Salisbury Wheel & Manufacturing Company, of Jamestown, N. Y., has leased the factory of the Straight Manufacturing Company, and will utilize it as an auxiliary plant. The concern has been working day and night, but has been unable to catch up to its orders. By the addition its capacity will be doubled.

Carpenter Steel Company Opens Hartford Branch—The Carpenter Steel Company, of Reading, Pa., has opened a branch office and warehouse at 189 Allyn street, Hartford, Conn. The business will be under the management of George S. Cairnes, who for many years has been identified with the tool steel trade of New England.

Countryman Automobile Company Retires—The Countryman Automobile Company, Minneapolis, Minn., has sold its business to the Heany Automobile Company of Aberdeen, S. D. The latter firm will retain its location in Aberdeen and in addition handle the Halliday cars from the Motor Mart for Minneapolis.

PERSONAL TRADE MENTION

Otis R. Cook, one of the best known men in the tire trade, and since September last manager of the tire department of the Federal Rubber Co., Cudahy, Wis., has just been appointed general manager, his jurisdiction having been extended to include the mechanical rubber department in addition to the tire department. Mr. Cook will make his headquarters as before at the company's Milwaukee office, corner Oneida and Milwaukee streets.

Frank L. Kingston, of Kokomo, Ind., who is the general manager of the recently incorporated Planhard Manufacturing Company, has been until recently associated with Byrne-Kingston & Company, of that city, of which concern his brother, George Kingston, is general manager. The latter is not identified in any way with the Planhard company.

Henry Haines Hower, well known as a writer on automobile topics, was married to Miss Loise Northrop, at Cleveland, on Tuesday of this week. Mr. Hower is the automobile editor of the Cleveland *Plain Dealer*, and Cleveland correspondent of THE AUTOMOBILE.

Robert P. McCurdy, of Pittsburgh, will have the agency in that city for the Pierce-Arrow automobiles. He has resigned from his position as manager of Banker Brothers, the agents for Chalmers-Detroit and Stevens-Duryea cars.

C. F. Baker has joined the forces of the American Motor Car Company, of Indianapolis, as sales manager. Mr. Baker has been identified for several years past with the Pope Company, at Toledo, O.

OBITUARY NOTICE

F. W. Hedgeland, president of the Hedgeland Manufacturing Company, of Canton, O., died on May 30. Mr. Hedgeland was the inventor of the equalizer which bears his name.

IN AND ABOUT THE AGENCIES

Maxwell, San Francisco, Cal.—The Maxwell-Briscoe Company is preparing to move to its new building at Fulton street and Van Ness avenue, which will be a distributing point for the Pacific coast and the western territory.

Babcock, Cleveland, O.—The Babcock Electric Garage & Sales Company has opened a new establishment on Euclid avenue, opposite Sixty-sixth street, to be devoted exclusively to electric automobiles, in addition to the Babcock.

N. Y. TRADE NAMES CUTTING

General John T. Cutting was elected president of the New York Automobile Trade Association in the recent annual meeting. The choice of the Oldsmobile representative was unanimous, and to serve with him the following were named: First vice-president, C. William Wurster, Stearns; second vice-president, C. P. Skinner, Mitchell; treasurer, Richard Newton, Stoddard-Dayton; secretary, Walter R. Lee, re-elected. The board of directors is made up of the following: C. Andrade, Jr., counsel; Frank Eveland, Stevens-Duryea; William Haradon, Columbia; G. W. Bennett, White; Harry Fosdick, Lancia; W. W. Burke, Mora; Peter Fogarty, Marmon, American Mors, Interstate, and A. J. Inderreiden, Warner Instruments.

General John T. Cutting

The financial report showed that the association is in a very flourishing condition, and a number of important movements are being carried on by it. Among these is the three-day endurance run to be held on June 12, 13 and 14.

NEW AGENCIES ESTABLISHED

Gaeth: Chicago—International Automobile Company, 1243 Michigan avenue.

Hudson: Boston — Whitten-Gilmore Company, for eastern Massachusetts.

Marion: Piqua, O.—H. B. Greenamyer.

RECENT INCORPORATIONS

Mutual Automobile Association, New York.—Capital $50,000. To manufacture automobile and other motor vehicles. Incorporators: F. Haasters, G. L. Clarke, O. B. Bachman.

20th Century Motor Car & Supply Company, Indianapolis.—Capital $60,000. To manufacture automobiles. Incorporators: M. L. Williams, H. E. Keyer, H. L. Wolverton.

Auto Appliance Company, New York.—Capital $25,000. To manufacture shock absorbers for automobiles. Incorporators: W. J. Singer, J. W. Lowell, J. L. Douglass.

Manlius Motor Company, Syracuse, N. Y.—Capital $20,000. To manufacture gas engines and deal in automobiles. Directors: G. A. Fowler, M. J. Topp, W. H. Topp.

Custer Manufacturing Company, Marion, Ind.—Capital $12,000. To manufacture automobiles. Directors: Angela G. Custer, Burr Custer, G. D. Custer, R. J. Custer.

Michigan Crank Shaft Company, Muskegon, Mich.—Capital $10,000. To manufacture crankshafts for automobiles.

Elton Auto Repair Company, Youngstown, O.—Capital $25,000. Incorporators: Fred Tod, Albert Elton, B. M. Campbell.

RECENT PUBLICATIONS

Fried-Ostermann Company, Rockford, Ill.—Price automobile gloves are well described in a beautiful little booklet issued by the Fried-Ostermann Company, of Rockford, Ill., the successor to the H. W. Price Company. The catalogue is printed in colors and with designs that are very attractive, aside from their value in an advertising sense. The cover is a pretty color plate of a man and a woman in an automobile, showing Price gloves on their hands, but not making them so exceedingly prominent to detract from the picture itself. This is true also of the frontispiece. The catalogue describes a great many kinds of gloves and gauntlets, in colors, telling of their quality, goods and price. The cuts are all so clear that a pair of the articles might be ordered without having really seen them, and yet their appearance would accurately be known.

Buckeye Jack Manufacturing Company, Louisville, O.—Automobile jacks in six sizes are manufactured by the Buckeye Jack Manufacturing Company of Louisville, O., with capacities of one ton, except one style with a lifting capacity of 1,800 pounds. This concern is well and favorably known as a maker of compound lever truck and automatic jacks, especially for use on railroads, and the automobile devices are made of the same quality of material as used in the machines which can lift 15 tons. These are all described in catalogues recently issued, giving detailed specifications, such as raise of bar, weight, price, size of base, and other particulars of interest both to the manufacturers who supply jacks with their complete automobiles or to the owner who is equipping a car.

THE ELECTRIC CARRIAGE

By the Waverley Poet

It does not shy at papers as they blow along the street,
It cuts no silly capers on the dashboard with its feet;
It does not paw the sod up all around the hitching post,
It does not scare at shadows as a man would at a ghost;
It does not gnaw the manger, it does not waste the hay,
Nor put you into danger when the band begins to play.

It makes no wild endeavor to switch away the flies,
It sheds no hair whatever to get in mouth and eyes;
It speeds along the highways and never looks around,
For things that it may scare at, and spill you on the ground;
It does not mind the circus—it's not at all afraid,
And does not overwork us when the elephants parade.

It does not rear and quiver when the train goes rushing by,
It does not stand and shiver when the little snowflakes fly;
It does not mind the thunder nor the lightning's blinding flash,
It does not keep you chirping and connecting with the lash.

When you chance to pass its stable you do not have to care,
Or cluck for all you're able to keep from stopping there;
There's no one to arrest you if you do not treat it right—
It will work all through the daytime and still be fresh at night.
It's a thing of proper manners which it shows in various ways,
So that all men and women are saying nowadays:
"It may once have been the thing to 'hitch your wagon to a star,'
But now to be quite in the swim you must hitch to a Waverley Car!"

Information for Auto Users

No-Klog Gasoline Filter—While it is a well-known fact that the fuel used in automobiles is very carefully guarded against dirt and water, it is also a fact that any car with a good filter will give better results than one without. To supply this need the Standard Gasoline Filter Company, Attleboro, Mass., is putting out the No-Klog filter, which has a number of excellent features to commend it. The filter serves a fourfold purpose, as it extracts dirt, separates out water, by purifying the fuel increases the power, and acts as an auxiliary reservoir. In its construction the best of brass is used, the design being such as to allow the ready removal of the strainers, the withdrawal of the entrapped water, has standard pipe connections for all commercial sizes, and fine threads, twenty to the inch, which aid in keeping the elusive gasoline from leaking away, as well as keeping out objectionable dirt and other foreign matter. The device is small, compact, not expensive, attaches in any position whatever, and is readily put on or taken off. The makers state that no autoist who has ever tried one and found out the benefits to be derived from it would thereafter be without one.

NO-KLOG GASOLINE FILTER

Displayed a Marked Fondness for the Bottle—In the recent spectacular parade of the New York Trade Carnival, the float representing the Thermos bottle was enthusiastically received, the applause all along the route, and the awarding of the second prize seeming to indicate the marked fondness for "the bottle" in general and the Thermos bottle in particular. The float was a gigantic representation of a Thermos bottle laid on its side, enthroned upon which was a beautiful young woman driving a flock of white doves with ribbons. The wheels were hidden by stationary shields so that no motion could be seen, and the effect of the flying dove providing the motive power for the vehicle was complete. The bottle is made by the American Thermos Bottle Company.

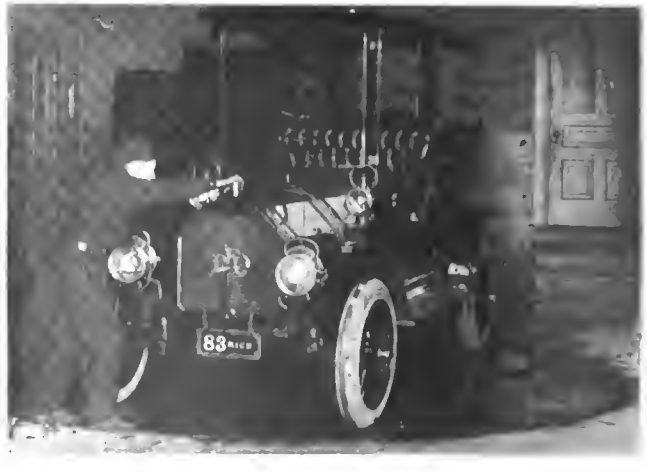
THERMOS BOTTLE FLOAT IN PARADE

Quick-Detachable Pump Connection—Speed is the cry to-day, and in the interests of obtaining this much-desired quality, even the little accessories are receiving their share of attention. A very new one, right up to the minute, so to speak, is the pump connection, a very minor accessory. Yet a new pump connection is now being marketed, which has the desired quality incorporated in its construction. This is the "Grab" connection, the name having been selected as indicative of the method of working. It differs from the usual connection in that the fastening is a clamp and not a screw or push connection. This allows of the rapid attachment or removal, and as it will fit any valve, with no chance of getting out of order, is doubtless in line for popular adoption. The makers' claim of simplicity and fool-proof construction is seen to be well founded. It is sold by the Motor Car Equipment Company, 1727 Broadway, New York City.

GRAB PUMP CONNECTION

A Ball-Bearing Turntable—Many automobile accidents are caused by cars backing out of garages and other places, through inability to turn in the limited space within. To overcome this, a turntable provides a means of turning a car in its own space, and every garage should have one. The Lansing Wheelbarrow Company, Lansing- Mich., is the manufacturer of an efficient device of this sort. This light, but strong, turntable, is built right into the floor of the garage and, being mounted upon ball bearings, turns very readily even with the heaviest machine upon it. The turntable not only avoids the chances of accidents due to the backing out process but removes the possibilities of damage to the machine itself on the curbstone or otherwise, and represents less heavy labor and therefore better work on the part of the employee.

In the illustration of the turntable in practical use in a garage, a car is shown in place with a man working upon it, the whole showing how readily one man may handle even a very heavy car when placed upon the turntable, the latter operation requiring possibly three or four men. In this way the saving due to the use of one of these devices is pictured in a striking manner.



CAR ON LANSING WHEELBARROW COMPANY'S TURNTABLE

Let the Auto Do the Work—In the inflation of tires by the old back-breaking way, with a hand, or, as it is sometimes called, a foot pump, much good energy was wasted which might have been put to an otherwise good use. The modern way of inflating tires takes care of this and now there are on the market a number of mechanical means of doing this work. One of the best of these is the E-Z Auto Pump Attachment, made by Wheaton & Cummings, Sunbury, O. This works on the eccentric principle, that is, the free end of the pump is fastened to the spokes of the wheel, which, of course, would place it off center or eccentric. The amount of this eccentricity determines the stroke of the pump. The other or delivery end may be fastened to the running board, or it may be placed on the ground or floor and held with the foot. The revolution of the wheel, which had previously been jacked off the floor so as to be free to rotate, operates the compression and delivery of air to the desired place. The whole outfit is very simple, consisting of a pump barrel with a hinged foot plate, and the clamps to fasten the driving end to the wheel. Being so simple or composed of so few parts, it is readily attached to or detached from the wheel.

E-Z TIRE PUMP READY FOR USE

VOL. XX NEW YORK—THURSDAY, JUNE 17, 1909—CHICAGO No. 24

THE AUTOMOBILE

A CONTEST TOUR WHICH EMBRACED FOUR STATES

By W. McK. White

IDEAL touring conditions—fascinating scenery, magnificent roads, nearly perfect weather—and an endurance contest in which a dozen of seventeen starters finished with perfect scores were experienced by those who participated in the "week-end" tour of the New York Automobile Trade Association. Leaving the busy city on Saturday morning for Catskill, thence to the Berkshire Hills on Sunday, and a run from Pittsfield to the metropolis on Monday, gave a route replete with scenic grandeur, and on such splendid highways as to mark this 350-mile trip as one of coming wide popularity. Ramapo Hills, Catskill Mountains and the far-famed Berkshires, interspersed with glimpses of the Hudson and other rivers, can furnish more beautiful vistas than will be found within a short radius of any other large city. The contesting nature of the tour introduced a spiciness which lent particular interest, and the rules were not so rigorous as to detract from the pleasures of leisurely traveling—a really delightful combination.

White, Franklin, National, Knox, Franklin again, Oldsmobile, Columbia, Mitchell three times, Interstate and Thomas taxicab were the makes which traveled the 351.2 miles on a time schedule with checking stations at frequent intervals, without being late or having to make adjustments on the roads. Stevens-Duryea, Stoddard - Dayton, and Mitchell were penalized, and Stoddard-Dayton and Standard withdrew, but continued as non-contestants. The one free-lance of the party was a Lancia. The automobiles which were penalized or withdrew were the victims of slight derangements, which would be overlooked in ordinary touring, or perhaps prevented, but which in a contest caused a disturbance. Only one serious mishap occurred, and that was to a touring car making its début in the metropolitan trade circles, the Standard, a production of the Standard Roller Bearing Company in Philadelphia. In rounding a corner in Kingston, N. Y., the car skidded and broke a wheel against a curb. A new one was sent all the way from the Quaker City and the car joined the contestants at Catskill on Sunday morning, and ran on schedule to the finish.

Fuel Is Always Necessary

The big six-cylinder Stevens-Duryea ran out of gasoline just as it was about to cross the line at Catskill, and after it stood at the checking station for twenty minutes with its motor running. It took some time to procure gasoline and 14 points were thereby rung up on the finish judge's register. A. H. Whiting's Stoddard-Dayton broke a gasoline feed pipe and after fixing this and securing a fresh supply of the valuable liquid, the car was so late that its entrant decided to withdraw and run as a non-contestant on the last day. The Stoddard-Dayton entered and driven by R. T. Newton had to break a seal for a carbureter adjustment, at a cost

of 6 points, and O. R. DeLamater on the second and third days stopped to renew his supply of gasoline and water outside of the controls. His penalty on the second day was 23 points, and on the last was 20 points, a total of 43. The rules allowed renewal of fuel only at checking stations.

As was forecasted by those who had been over the route, the tourists were greatly pleased and impressed by the wonderful scenery. The party formed at Columbus Circle on Saturday morning under a blue sky and a bright sun predicting fine weather, and with police escort, proceeded down Broadway to Forty-second street, thence to the Weehawken ferry. On the heights above the Hudson the cars drew up in line, and a few minutes after 9 o'clock the Stevens-Duryea, driven alternately by Frank Eveland, of New York, and his son, F. W. Eveland, of Philadelphia, was sent away, acting as a contesting pacemaker. The Columbia touring car, which carried checkers, was also a contestant, and as a rule checked out of the controls some time earlier than the body of the tour, and finished in the same relation.

Hardly more than a few miles out of Weehawken the beautiful views came into evidence. Suffern was the first checking station, 28.3 miles from the start, with a schedule of 1 hour 50 minutes, and the roads as fine as the best in the world. Hard and smooth highways, in many places oiled, were conducive to enhancing the pleasure of the run through the Ramapo hills, considered by some as more beautiful than the Berkshires. A second control furnished equally grand roads and views to Highland Mills, and then a detour was made to the Lake View Hotel for lunch. There occurred something here which reminded those of the tourists who have been in Gliddens and other long trips of the rush when a route has to be altered. R. H. Johnston had laid out the directions, but since his trip part of the State road into the hotel had been torn up, and three-eighths of a mile in the route book lengthened into three miles of roads that turned and twisted every hundred yards. Consequently, many drivers discovered that they had but a few minutes, and the way they came rushing into the control was far different from the quiet pace held throughout the remainder of the trip. None was late, for a wonder, but it was a close shave for many.

After a stop of an hour and a quarter the party proceeded toward the next checking station, at Highland, regretting that they did not have more of the beauties of the country around Suffern, Tuxedo Park and Arden, but looking forward to the Catskills. Newburgh was on the route, but no stop was made, although the reception accorded the travelers was as hearty there as at all places. From that city the road lay along the bank of the Hudson, and with the afternoon sun shining upon the eastern shores there were many places where the beauties of nature and of the mansions across the river caused the drivers to run very slowly. From Kingston the cars ran through Esopus, wound for seven miles to go one mile into Kingston, and stopped for the night at the Grant House on the outskirts of Catskill. The run of the day had been 125.2 miles in length, and the running time was seven and a quarter hours.

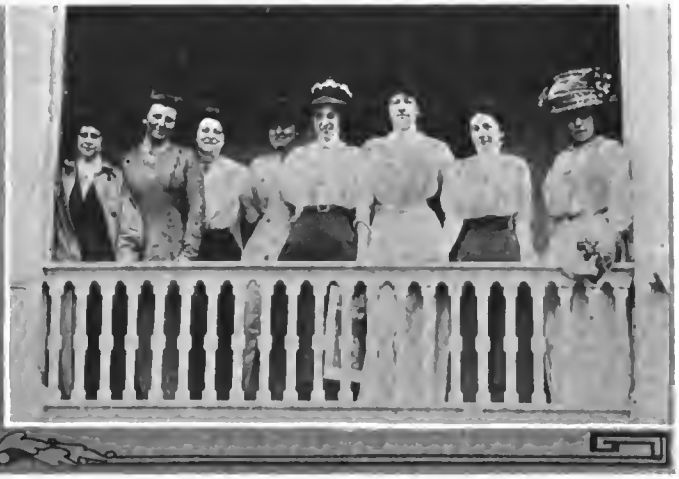
An innovation in a tour of the kind was introduced by giving over Sunday morning to the tourists, for runs back into the mountains or for a quiet rest. Each day as soon as the cars were checked into the night control and a count of the seals upon the bonnets was made, the drivers were free to use them as they liked. At Catskill several of the cars made short runs, and one fishing party was organized by Senator W. J. Morgan. The party was a success, although the fish were not. After dinner the comparatively short run to the Berkshires was commenced. The distance was 74.4 miles to the Hotel Wendell at Pittsfield, and the time schedule was four and three-quarter hours, with one intermediate stop at Albany. The first bad

Peekskill Was a Typical Stopping Place on the Tour

roads of the trip were found between Athens and Ravena, 17 miles, and they were very rough, but only caused the contestants to go slowly. Soon after leaving the State capital the Berkshire hills came into view and the splendid roads wound up and down through the verdure-clad valleys right to the city. A light rain commenced before reaching Albany so that at that city tops were raised and rain garments donned. It was well that the opportunity was taken there, for the farther the cars went the harder the rain seemed to come down, and by the time Pittsfield was sighted it was very heavy. A number of the contestants had taken their wives upon the run, and a dinner party was formed on Sunday evening in the Wendell.

Monday's route was the longest, 151.6 miles, and the interest was just as great as on the previous days, for the route led through places which are known all over the country for their beauty: Lenox, Stockbridge, Great Barrington, Sharon and the Hudson river shores from Poughkeepsie to Yonkers. The rain clouds had cleared away and the day was the clearest of the trio, a fact that was greatly appreciated in going through the hills of western Massachusetts and Connecticut. As was expressed, the country appeared in the morning as if it had been carefully combed and groomed, the flowers were in full bloom, and the dampness of the previous day had given full grandeur to the entire scene. A run of 46.6 miles to Sharon was the first of the programme, and so well did the tourists like

Committee Which Successfully Carried Out the Run



Fair Ones Who Gave Committee Needed Assistance

the views on the route that they took it very slowly, the highways being wonderfully smooth and hard, only a few stretches around road-building operations giving slight roughness. From the quaint town of Sharon, with its clock tower, wide and shady lawns and hospitable inn, to Poughkeepsie, was a little over 30 miles, and in the city on the Hudson a stop was taken for lunch. At Cold Spring the first views of the river were seen, and the roads from Poughkeepsie to Peekskill were none too good, in fact the poorest of the trip; but the views around the Storm King mountains were worth the roughness. The drivers, however, had to do some fast running at the finish of the control, for many of them had taken matters too leisurely at the beginning, not expecting to be held down near the finish, and the result was that when the worst of the roads were met with the time did not allow of taking them slowly. All reported on schedule time.

From Peekskill to Yonkers was a quiet parade along the banks of the river, with wide views often seen from the heights, while underneath the roads were as fine as could be desired. From Yonkers into this city was of necessity an easy run, and all were so far ahead of time that no speeding was apparent, and the bicycle police rode alongside asking their acquaintances in the trade as to the pleasures of the route. As the contestants arrived at the Automobile Club of America they were immediately checked out, their seals examined and the cars and drivers released without waiting for the time schedule.

This circuit has been known to many autoists, but perhaps to not as many as might conveniently make the trip, and it is due to become equally as popular as the more generally used tours into New England. The fact that there were nine women passengers shows that it is easy, and they all expressed themselves as greatly pleased, and not at all tired. They were: Mrs. Harry Fosdick, Mrs. R. T. Newton, Mrs. A. J. Interreiden, Mrs. W. C. Poertner, Mrs. C. H. Larson, Mrs. W. R. Lee, Mrs. W. A. Krohn, Mrs. Marcus Allen, Mrs. L. C. Van Bever.

The cars themselves made the run in splendid order; there was very little tire trouble, perhaps not more than three or four changes; almost no stops for adjustments as the score shows; few cases of overheating, and the fact that eighteen cars, including Harry Fosdick's free-lance Lancia, can go through a 351-mile run without stopping, and the motors had to be kept running at all times except at the noon control, speaks well for the reliability of them. The little Thomas taxicab kept plugging along consistently and steadily, a remarkable performance for such a small car with a large body, and the crowd was frequently interested in seeing how much charges were rung up on its taximeter. Jones Speedometer and Warner Autometer Companies had sent out cars ahead of the tourists, and they marked the route with arrows, and on several detours the Warner signs were used instead of the route book. The big Oldsmobile with its 42-inch wheels, the same car which has taken part in many other contests around Philadelphia and won the run of the Norristown club, was driven by Fred Folberth of the Olds factory, and attracted considerable attention. Hal K. Sheridan had a White close-coupled tourabout, and as is the practice of the White drivers in contests, kept well to the rear, out of the dust, and drove to see the country rather than to have long waits in hot controls. The White showed its speed, however, when it was necessary to go three miles in 10 minutes over crooked roads into the Lake View hotel on Saturday. Two Franklin cars, a four and a six, represented the air-coolers, and as usual had no trouble from that or any other score, both carrying heavy loads. The big Stevens-Duryea took the palm, however, for the number of passengers, as it had its seven seats occupied at all times. The National car was a low, rakish, yellow roadster and it

created a favorable comment all along, not only because of its lines and novel color scheme, but also because of its steady running and quiet motor. The Mitchell was best represented in number, for there were four of this make and the three of 30-horsepower size all made perfect scores. The two Stoddard-Dayton suffered rather severely for the nature of their troubles, and, aside from the momentary adjustments necessary, ran splendidly. At one time the crowd around the checking station through that Mr. Newton had stopped his motor, when in reality it was only throttled down and running very quietly. A rock struck the gasoline feed pipe on Mr. Whiting's car, causing it to break. The Knox car entered by the New York Fisk branch was one of the perfect score contenders, as was also the Interstate driven by Harry Knepper.

FIVE BATTLING IN QUAKER ENDURANCE RUN

WILLIAMSPORT, PA., June 14—With a beggarly array of five starters, the Quaker City Motor Club this morning launched its five-day endurance run to Pittsburg and return. Various reasons have been given for the paucity of entries—lack of cars, preparations for 1910, etc.—but the fact remains that this territory has had a surfeit of endurance and reliability runs for this season, and the Quakers made the mistake of scheduling their run too late in the season; or, failing to secure an earlier date, of not calling the run off altogether. It is going to cost them something like $1,200 to see the affair through, and, like true sports, they are going to do it.

To-day's story is soon told. Shuttleworth, with a 40-horsepower Haynes, the only class C entry, snapped a front axle at Lavelle, 75 miles short of the overnight stop, and under ordinary conditions would have retired. But Shuttleworth is after the cup, and wired to New York for a new axle.

The Palmer & Singer covered the last 25 miles of to-day's run with two broken front springs, but by means of a first-aid repair got into the control on time.

The Franklin and the Elmore—the latter driven by Frank Hardart, Jr., the only amateur driver in the run—finished clean for the day in their class, as did Walter Cram's Mitchell 20 in class D. The going was horrible through the mountains, as a result of the incessant rains of last week, and the reduction of the running time to 18 miles an hour was much appreciated by the drivers. Seventy-five of the 191.2 miles of to-day's run was over and through the successive ranges of the Blue mountains which form the backbone of the Keystone State between the Delaware and the Susquehanna.

Pilot "Doc" Overpeck, who is acting as referee in the absence of Chairman Ross of the contest committee (who was called out of town), was compelled to transfer his flag to the Palmer & Singer, a troublesome clutch delaying the official Chalmers-Detroit, and it was overtaken by the former at Sunbury.

JOHNSTOWN, PA., June 15—The 18-mile-an-hour schedule obtained again to-day, and with the large proportion of low-gear work due to the mountains and the heavy going in many places the reduction came in quite handy. Although four of the five cars finished clean, none of them had much time to spare.

The surprise of the day was the appearance in Williamsport at 6 a. m. of the Haynes, which suffered a broken axle 75 miles shy of that place. Driver Shuttleworth and his assistant, with the aid of a fence rail and a little ingenuity, managed to get their car to Ashland, where a new axle, wired for to New York, reached them at 11 o'clock at night. They were back on the course again at 1 o'clock this morning, and reached Williamport in time to get a bite of breakfast before checking out.

There were some delay in the arrival of new springs for the Palmer & Singer, which limped into Williamsport yesterday with both front springs gone, and the car did not check out from that place till 8.45 this morning. By taking all sorts of chances and pushing through with but one three-minute stop for fuel, the car arrived here 6 minutes ahead of its schedule, and the performance is the talk of all Johnstown, where the character of the going along the route is well known.

The only car to suffer a penalty to-day was the Haynes. Yesterday's experience made Driver Shuttleworth a trifle too careful, and he failed to allow sufficient time for the mountain work between Altoona and this place; he checked in 15 minutes late. He is determined to land the class C cup, and as the Haynes is the only car in that class, he says he will not mind the addition of a few extra points to the large total accumulated yesterday.

Following is a list of the participants:

CLASS A

No.	Car	H.P.	Cyl.	Driver	Time	Penalties Work	Total
5	Elmore	35	4	Hardart, Jr.	0	0	0
13	Franklin	42	6	Carris	0	0	0
1	Palmer & Singer.	60	6	Wallace, Jr.	0	Incom.	Incom.

CLASS C

4	Haynes	40		Shuttleworth	Broken front axle	Incom.

CLASS D

6	Mitchell	20	4	Cram	0	0	0

NEW YORK, June 14—Twenty-five automobiles—all of them of one make, Maxwells—started from this city this morning on an eight-day tour, the first of such length and with but one kind of auto ever arranged. It is the annual tour of the Maxwell-Briscoe Motor Club and it includes on its route some of the most picturesque scenery in five States, New York, Connecticut, Massachusetts, New Jersey, and Pennsylvania. The party left the city in time to visit the Maxwell factory at Tarrytown and lunch was served there by the factory officials. Nearly all of the cars are privately owned ones and only the official machines are supplied by the makers. From Tarrytown the course leads to Waterbury, Conn., where the first night stop will be made. To-morrow there will be a leisurely tour through the Berkshires, stopping at Stockbridge. The third stage will carry the Maxwellites over into Pennsylvania, via Port Jervis, thence to the Delaware Water Gap, Philadelphia, Atlantic City, and back to New York. Next Sunday will be spent at Atlantic City, returning via Lakewood. A handsome trophy has been offered and it is for this that there will be competition.

WOMEN'S TOUR FROM COAST TO COAST

Transcontinental automobile touring is receiving another good impetus through the trip of Mrs. Alice R. Ramsey and three other women, who are en route in a Maxwell touring car. Fully equipped for a long journey, with camping outfit, shovels, and even firearms, the notable quartette left New York on the morning of June 9, during a drizzling rain, which neither dampened their spirits nor the intention of trying to reach Albany on that day. With Mrs. Ramsey, who is president of the Women's Motoring Club, of New York, are Miss H. Jahns, Mrs. W. Atwood, and Mrs. N. R. Powell, all of Hackensack, N. J., and it is their intention to do all of their own work on the way, thus being the first women to make the trip from ocean to ocean unassisted by mere man. Mrs. Ramsey intends to do the driving, although her companions are capable of taking the wheel if necessary. The route selected is that most generally used between the coasts: Albany, Buffalo, Cleveland, Chicago, Omaha, Cheyenne, Ogden and Reno. No speed will be attempted, but the party expressed the hope of reaching the Pacific Coast by the middle of July, and perhaps a few days earlier.

Plans have been made to stop in cities and towns at night, but if that is not possible at any point, the camping outfit will be called into use, including its cooking utensiles, for a supply of food and water will be carried while crossing the plains. The firearms, Mrs. Ramsey explained, "are to scare away any over-curious wild animals," and the shovels and axes for emergency use. After reaching San Francisco the women expect to tour in the southern part of the State.

SHAWMUT LEADS IN OCEAN-TO-OCEAN RACE

RAWLINS, WYO., June 15—In the heart of the Rocky mountains the automobiles participating in the endurance contest from New York to Seattle are experiencing great difficulties. The roads have been very bad ever since the cars entered Kansas and the fortunes of the race have caused each car at times to be the leader, and at times the last. The Shawmut is leading at present, having left this place at noon, and the two Fords left together at 4.45 p. m. The Acme has not as yet reached Cheyenne. On last Thursday the contestants were at Ellis, Kan., where the Acme led, with the two Fords together, and then the Shawmut, all close together, but the Shawmut took second place by leaving ahead of the small cars. At Limon, Col., on Saturday the Shawmut was leading, with Ford No. 2, and Ford No. 1, in the order named. The Acme had to stop at Oakley, Kan., but followed the others after several hours delay. Cheyenne on Sunday reported that the Ford No. 2 was the first to arrive, followed in a few minutes by the Shawmut, with the Ford No. 1 in Denver, and on the same day the Itala was struck by a freight train on a bridge at Marshall, Mo., but was not badly damaged.

Yesterday the Shawmut took the lead by reaching Laramie first, and the two Fords joined forces at Cheyenne and proceeded. The Acme reached Denver. Last night the Shawmut was held up at the Union Pacific bridge over the Platte river at Fort Steele because it did not have a permit to cross, and it had to spend the night there. The Ford drivers, however, had secured the passes in Cheyenne and No. 2 crossed, thus taking the lead and stopping here for the night. No. 1 reached here at 10 o'clock this morning, just as the Shawmut received permission to cross the bridge. The Ford No. 2 started from Rawlins early to-day, but something broke about six miles out and it was brought back. When the Ford No. 1 arrived it had a badly crippled wheel, having broken it on the bridge. The Shawmut thus caught up and passed, and was reported at Wamsutter, 40 miles west, just as the Fords left here. The last reported of the Acme was that it was in a mud hole south of Cheyenne.

MERIDEN WILL HAVE A HILL CLIMB

MERIDEN, CONN., June 14—A hill climbing contest which will be open for amateurs only will be held by the Meriden Automobile Association on June 26. Considerable rivalry has arisen as to the abilities of the cars owned by some of the members and the entry list has been filling rapidly. The machines will be classed by piston displacement instead of price, and there will be seven events, as follows: Displacement of 160 cubic inches or under; 161 to 230 cubic inches; 231 to 300; 301 to 450; free-for-all; single-cylinder motorcycles; and two-cylinder motorcycles. Mayor Reilly and other city officials will preside.

CLIMBING A HILL CALLED "DEAD HORSE"

Thousands came early and climbed

Cameron, twice winner with Chalmers-Detroit.

WORCESTER, MASS., June 12—"Dead Horse" Hill is the name of an incline that is known throughout the country because of its unusual cognomen. Many a horse was "dead" by the time he reached its highest part, though there are other grades in the "Old Bay" State which call for more endurance and persistence. "Dead Horse" has had its surface improved in recent years, along with many other miles of good highway in Massachusetts, and consequently its climbing no longer presents any terrors even for the harnessed animal.

Steam had its innings to-day, for the craft piloted by L. F. N. Baldwin made the ascent in 54 seconds flat, which was an improvement of 1 3-5 seconds over his time of a year ago. Again, in the "record-of-the-hill" event, the steamer scored in .55 3-5, and Baldwin might have done even better had he so desired.

Baldwin to-night made the public statement that he would never drive again, due to the wishes of his wife, who has convinced him that the risk is too great for the honors to be gained.

The best time made by a gasoline car was in the "record-of-the-hill" event, when H. F. Grant, in the Alco, formerly the Berliet, made the ascent in 1.03 4-5.

The Benz car, with David Bruce Brown driving, came to grief the night before the climb in trying out the hill. Brown was making the hill at a 50-second clip when he met a lightweight Stanley coming in the opposite direction.

This morning William Bourke, in his racing Knox, went into the gutter on the same section of the hill where Brown and the Benz went to the bad, and the Knox was smashed beyond repair and Bourke had to be taken to a physician.

It is to the credit of the Worcester Automobile Club, particularly of John P. Coughlin, its president, that the climb was run off in less than two hours. The time of running the events was 1 hour and 47 minutes, and this was due to Fred J. Wagner, the starter, who insisted that a car be off every two minutes.

Prominent autoists from all over New England were present, the honorary referee being President L. R. Speare, of the American Automobile Association. The acting referee was Samuel B. Stevens, who was recently appointed a member of the A. A. A. board.

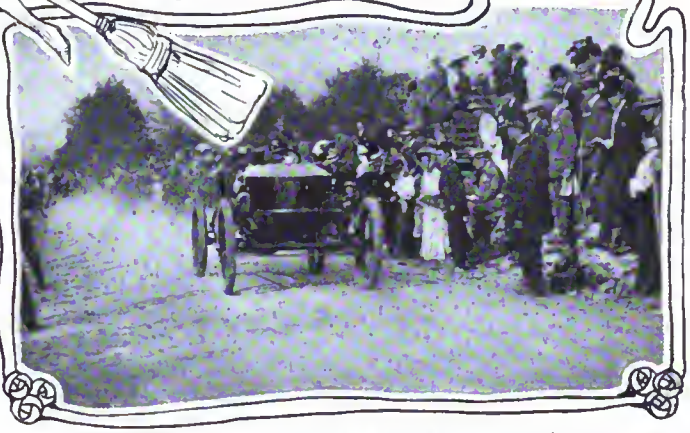
A contingent from Lowell included Mayor Brown, Secretary McKennna of the board of trade, Senator Hibbard, and Thomas Lee, all being guests of President J. O. Heinze, of the Lowell Automobile Club. The following is the summary:

Where the Timers were "Cooped"

Burnham scored with Simplex.

LOCATED IN THE "OLD BAY STATE"

And the 'Cops" marched up hill.



Baldwin who "steamed" to victory.

FREE-FOR-ALL, GASOLINE CARS WITH DISPLACEMENT OF 451 TO 600 CUBIC INCHES

Pos.	Car	H.P.	Driver	Time
1	Alco	54.1	Harry F. Grant	1:03 4-5
2	Allen Kingston	48.4	H. Hughes	1:07 4-5
3	Allen Kingston	48	C. A. Glenworth	1:14

FREE-FOR-ALL, GASOLINE CARS WITH PISTON DISPLACEMENT NOT TO EXCEED 350 CUBIC INCHES

1	Columbia	32.4	J. J. Coffery	1:08 4-5
2	Buick	32.4	J. B. Ryall	1:22 1-5

FREE-FOR-ALL, CARS OF ALL TYPES AND MOTIVE POWERS

1	Stanley		L. F. N. Baldwin	0:54

A Look at Eight-Cylinder Engine and Propeller on Bleriot's Twelfth Monoplane, Just Produced

BLERIOT'S TWELFTH MONOPLANE

PARIS, June 10—Louis Bleroit, the French monoplane enthusiast, has just produced his No. 12, an improved type of monoplane flying machine driven by a 50-horsepower, eight-cylinder E. N. V. engine, the features of which were set forth in a recent number of this paper. The new flyer has its engine full forward and attached to the lower members of the frame, the drive being by chain to a two-bladed wooden propeller revolving at about one-third the engine speed. The pilot's seat is under the center of the wings, and to the rear of the engine, in which position he is only a few inches from the ground when a start is made, and has room for a passenger by his side. A pleasing feature of the aeroplane is the very neat arrangement of plain radiating tubes in the framework of the machine connecting the wings to the tail. In this position the tubes offer no resistance whatever to the advance of the aeroplane and yet profit by the current of air set up when flying. The tail of the aeroplane has been considerably improved on the previous models in order to give increased stability. It is composed of three vertical rudders, operating together and allowing of lateral movement, and a couple of horizontal pivoting planes regulating the height of the machine in the air.

The first important journey of the new aeroplane was intended to be a repetition of Bleriot's first cross-country trip from Toury to Artenay, undertaken last October. This could not be covered in its entirety, for after traveling nine miles across country the gasoline supply became exhausted and it was necessary to seek external aid for the return portion of the trip. The attempted round trip was made on the occasion of the inauguration of the monument in honor of last year's exploit.

FRANCE HAS BUILT RUSSIA'S AIR CRAFT

PARIS, June 10—France is about to deliver to Russia her first aerial cruiser, the *Russie*, constructed in the Lebaudy shops at Moisson, near Paris, on practically the same lines as the successful *Republique* for the French army. Trial trips have taken place this week around Paris in the presence of a group of Russian officers sent here to inspect the airship. The overall length of the *Russie* is 170 feet, and her cubic capacity 12,000 feet. Her envelope is made of rubbered cloth supplied by the Continental Company. Her power plant consists of one four-cylinder Panhard-Levassor engine of 80 horsepower, driving two pairs of propellers, and capable of giving to the aerial vessel a speed of 40 miles an hour in still air. The *Russie* will shortly leave for her home station, and will be housed in a special dismountable shed built for her by the American engineer, Melvin Vaniman.

HERRING GETS EXTENSION OF TIME

WASHINGTON, D. C., June 14—The War Department, it is understood, has not only granted A. M. Herring an extension of the time for the completion of the tests of his aeroplane, but has waived the date of delivery. The only requirement now is that the aeronaut complete his trials by July 1.

CURTISS AEROPLANE AT MORRIS PARK

NEW YORK, June 14—Interest in aeronautical circles is centered in the assemblying and testing of the new Curtiss light biplane which has arrived at the Morris Park grounds. The entire machine weighs but 550 pounds with the operator, and will be tried before the public exhibition on June 19 or 26.

St. Louis Will Get a Wright Flyer—A special committee has been appointed by the Aero Club of St. Louis to confer with the Wright Brothers relative to giving an exhibition in connection with aerial events scheduled for October. If neither of the brothers can attend the club will purchase a machine and have it operated by one of the Wright students.

Boston "Tech." Will Give Aeronautic Course—Prof. R. C. MacLaurin, the new president of the Massachusetts Institute of Technology, is planning a course in aeronautics for the opening of the institute next year. It will include practical work in designing, building, and operating various types of machines.

From Brownsville, Texas, comes a story of the successful trial trip of the first aeroplane constructed in the Lone Star State: "Prentice A. Newman, in an aeroplane designed along new lines, made a successful flight of about half a mile, towed by a 45-horsepower Pierce-Arrow automobile. The aeroplane had not been equipped with its own propelling mechanism but its inventor desired a trial, and a three-quarter-inch rope, about 182 feet long, was attached. The day was clear with a head wind of from 12 to 15 miles an hour velocity. At eight miles an hour the aeroplane cleared the ground; at 10 to 12 it rose fairly in the air, carrying the inventor, of course, and at this low rate the towing became very easy; at a speed of 25 miles an hour the towing line was at an angle of approximately 45 degrees, giving the machine an altitude of from 90 to 130. The aeroplane then balanced perfectly in all positions of the wind, and when the car slowed up the aeroplane coasted on its own momentum for two or three hundred feet. Mr. Newman then swung it to one side by the steering gear, to avoid some trees, and it landed easily."

CLEVELAND CLUB'S CLIMB UP PORTER HILL

CLEVELAND, June 14—Unfortunate is the proper word to apply to the Cleveland Automobile Club's choice of a day on which to hold the annual hill-climbing contest. As first scheduled, the races were to come off on June 5, but the weather man being contrary at that time, the first postponement to June 9 was made. On that day things did not look much brighter, but several days of continuous downpour had so scared the committee that they decided to hold it anyhow. The rains had put the scene of the day's activities in the worst possible condition, so that it was necessary to put scrapers on the job for more than a few hours before the surface of Porter Hill was fit to use.

Owing to the postponements and the bad day the entrants were reduced in numbers, so that it was necessary to eliminate several of the carded events. Those remaining were well contested, and the enthusiasts from the city, as well as the farmers from nearby, enjoyed a good day's sport.

Next to Knox, which cleaned up no less than four events and made the fastest time of the day, Mrs. Otis and the little Hupmobile shared the honors. The former sent her big Stearns roadster up the half mile grade from a standing start in the fast time of 51.2 seconds. This was not a contest, but an exhibition, and the time made was the fifth best of the day.

The Hupmobile created a sensation by winning two events, the only ones in which it was entered. The striking feature of the car was its size, being so small as to be dubbed "The baby of the meet." The original program made no provision for the motorcyclists, but on the spur of the moment a contest for them was organized and run off. This was very successful and the time made by the winner, A. W. Strople, on an Indian, was beaten only by the flying Knox. Strople made the steep ascent in 42.5 seconds.

All of the contestants seemed to be familiar with the hill, showing that much preliminary work had been done in anticipation. The officials ran the events off in good shape, notwithstanding the weather conditions. The final event, number eleven, was a piston displacement handicap, in which, some insist, the final results still seem to be in doubt.

The White gasoline car, winner in the $2,000 to $3,000 touring class, was the product of the newly formed White Motor Car Company, and is not to be confounded with the newer venture of The White Company, the well-known builders of steam-driven automobiles, which has recently added a small gasoline model to its line. The results follow:

GASOLINE STOCK CARS, $2,001 TO $3,000, TOURING CARS

Car	H.P.	Bore	Stroke	Driver	Time
White (Gasoline)	45	5	5	Camra	1:11 1-10
Chalmers	45	4 1-5	5	Davis	1:36 5-10

GASOLINE STOCK CARS, $2,001 TO $3,000, RUNABOUTS

Knox	40	5	4 3-4	Belcher	:48 9-10
Pullman	40	5	4 3-4	Hardesty	1:08 7-10

GASOLINE STOCK TOURING CARS, $1,251 TO $2,000

Oakland	40	4 1-2	5	Dennison	:59
Pullman	40	5	4 3-4	Hardesty	1:21 1-10

GASOLINE STOCK RUNABOUTS, $1,251 TO $2,000

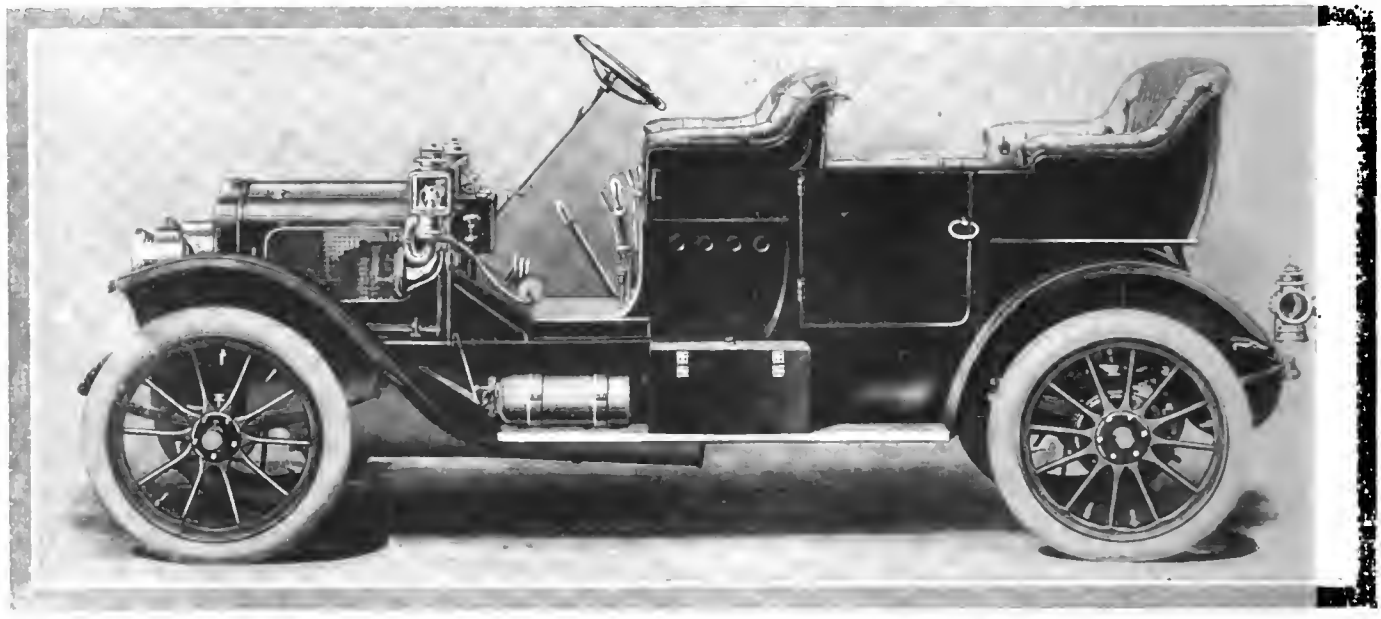
LOWELL GETS NATIONAL STOCK CAR RACES

LOWELL, June 14—Detailed arrangements for the national large and small stock car races that are to be held over the Merrimac valley course in this city during Labor Day week, will now be perfected, the final agreement with the Contest Board of the A.A.A. having been concluded last week. It appears that there was a misunderstanding concerning the attitude of the contest board toward the races and the Lowell club.

It had been stated that in addition to the sanction fee the board had demanded an absolute guarantee of a large sum of money, as a condition of the national events being held in Lowell. Concerning this matter President John O. Heinze this week met Chairman Hower and found that the report of the A.A.A.'s attitude was incorrect. What the A.A.A. asked was that it be given a preferred claim on a part of the net profits to cover the expenses to which it will be put on account of the race. Net profits are understood to mean any sum remaining after all the bills, including money advanced by citizens, are paid, and which would go into the treasury of the Lowell club. This arrangement is satisfactory to the club.

It has been decided to recover the same ten-mile circuit that was used last fall, the club officials being confident that all the cars that are entered can be started on this circuit, and that a much more interesting event will result than if the circuit is extended to fifteen miles or more as is possible. The city of Lowell and the club are prepared to spend about $12,000 to put the course in shape and with this expenditure the circuit ought to be the best in the country, for about half of it is State highway already in excellent shape. In place of the hairpin turn at the Tyngsboro end of the circuit, a new macadamized road, scientifically banked, will be constructed, so that the cars can whirl around from the boulevard into the back-stretch without skidding and at full speed. All parts of the back stretch and of the lower cross road will be put in first class condition.

The grand stand is to be constructed on the boulevard where the spectators will have a fine view of the racing cars, and it will be built to seat 10,000 people. Its back will be to the Merrimac river and across the river at that point a pontoon bridge with a twelve foot walk will be built. On the opposite side are the tracks of the Boston & Maine railroad and of the trolley line. This plan will make access to the course much easier than was the case last year. The entry blanks will be prepared by the contest board of the A.A.A. and will be issued very soon. Trophies will be offered in both races, but the names of their donors have not yet been announced.



Model "O O" Twenty-Horsepower White Steamer Presents Unusually Attractive Lines

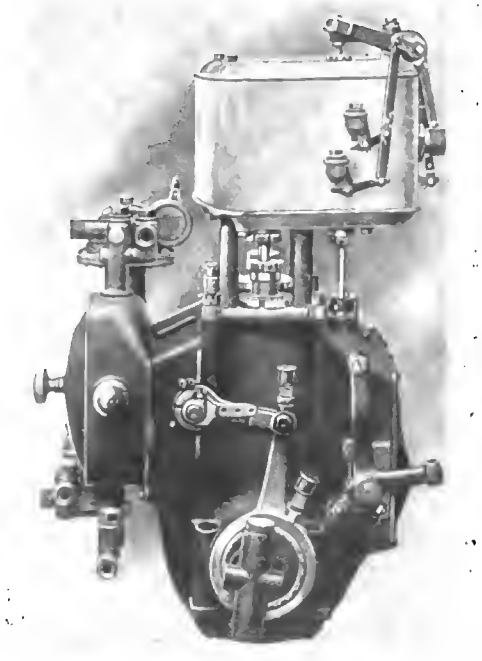
WHITE CARS FOR 1910 INCLUDE A GASOLINE

THE 1910 models to be made by the White Company comprise a 20-horsepower steam car selling at $2,000; a 40-horsepower steam car selling at $4,000, and a 20-horsepower gasoline car which will be made in two types, differing in details of running gear and body construction, but with identical power plants. These two types will sell at $2,000 and $2,500 respectively. All of the above prices are f. o. b. Cleveland and are for cars with touring, toy tonneau or runabout bodies.

The most important new feature in the 1910 White Steamers will be, as already announced, the modifications whereby either kerosene or gasoline may be used as fuel. Plans have been made for building a greater number of steam cars than have been turned out in any previous year, and shipments from the factory will commence before July 1. The design of the gasoline car and the materials used in its construction are in accordance with the most advanced and modern foreign practice.

The 20-Horsepower White Steam Car—Considering, first of all, the 20-horsepower steam car; this will be known as the Model "O-O," and will be the successor of the Model "O" of the present season. The most noticeable change in the external appearance of the new model is a lengthening of the wheelbase to 110 inches. The frame has been lengthened and the power plant moved back so that the front axle is immediately under the condenser. The shape of the mud guards has been somewhat changed, as will be seen in Fig. 1. The engine is compound, vertical, and of the same compact construction as in the 1909 model, with a high-pressure cylinder of 2½-inch bore, a low-pressure cylinder of 4¼-inch bore and a stroke of 3 inches. The crankshaft is a short, one-piece forging of tool steel with but two main bearings. Both the high-pressure valve and the low-pressure valve are piston valves and are driven direct from the connecting rods by what is known as the Joy valve mechanism. The two main bearings and the two connecting rod bearings are fitted with ball bearings of unusually large size.

A change has been made in the method of driving the two pumps which supply water to the generator. Instead of being driven from the valve gearing, as in the 1909 engine, they are driven from an eccentric. This eccentric is located outside of the crankcase at the rear of the engine and is forged integrally with that part of the universal joint which is attached to the crankshaft, as clearly shown in the accompanying picture. As in the 1909 engine, the pump which returns water from the condenser to the tank and the air pump which supplies pressure for the fuel tank and for inflating tires are driven directly from the valve mechanism.

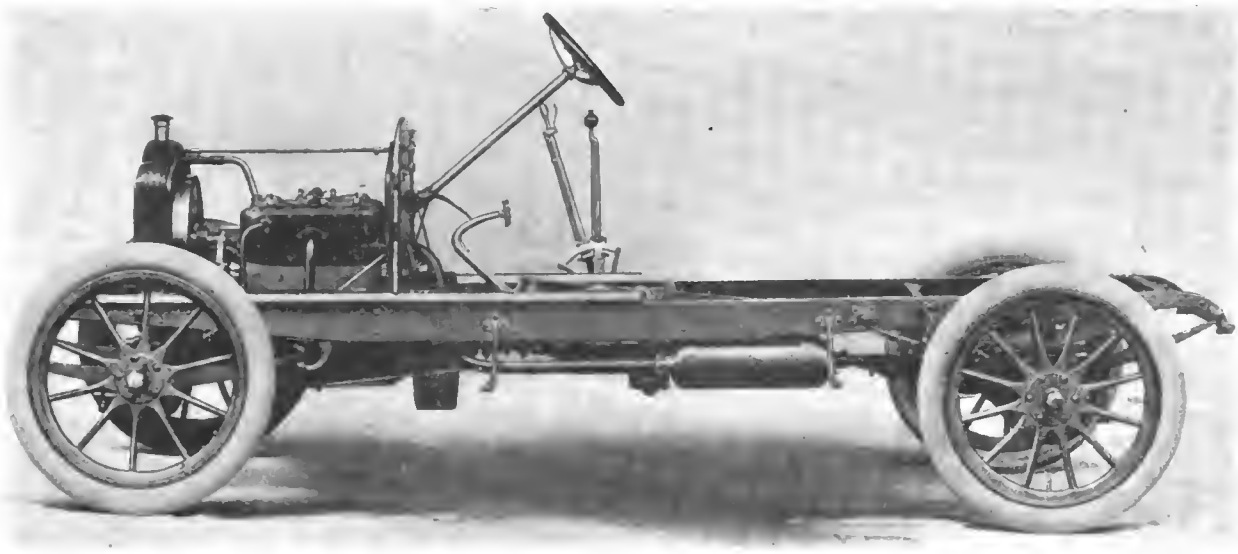


Rear View of 1910 White Engine

Showing the eccentric for driving the water pumps. The 40-horsepower engine and 20-horsepower engine are identical, except as regards dimensions.

The frame of the Model "O-O" is of pressed steel; the tires, both front and rear, are 32 x 3 1-2; the front axle is of I-beam section and all the bearings in the car are annular ball bearings.

The 40-Horsepower White Steam Car—The 1910 40-horsepower White Steamer will be known as the Model "M-M," to indicate its close relationship to the Model "M" of the past season. The most marked change in the external appearance of the new car is that the steering post is tilted considerably more than in the previous model and the shape of the mudguards has been changed. The wheelbase remains unaltered at 122 inches. The frame is of steel, replacing the armored-wood construction formerly used. The "M-M" engine has all the characteristics of the Model "O-O" engine, described briefly above, including the feature of driving the water pumps by means of an eccentric located outside of the crankcase. The dimensions of the Model "M-M" engine are: High-pressure cylinder, 3-



The New White Gasoline Chassis Shows Classy Design and Up-to-Date Constructive Features

inch bore; low-pressure cylinder, 5-inch bore, and stroke, 4 1-2 inches, the same as in previous models.

The Model "M-M" is equipped with 36 x 4 tires on the front wheels and 36 x 5 tires on the rear wheels.

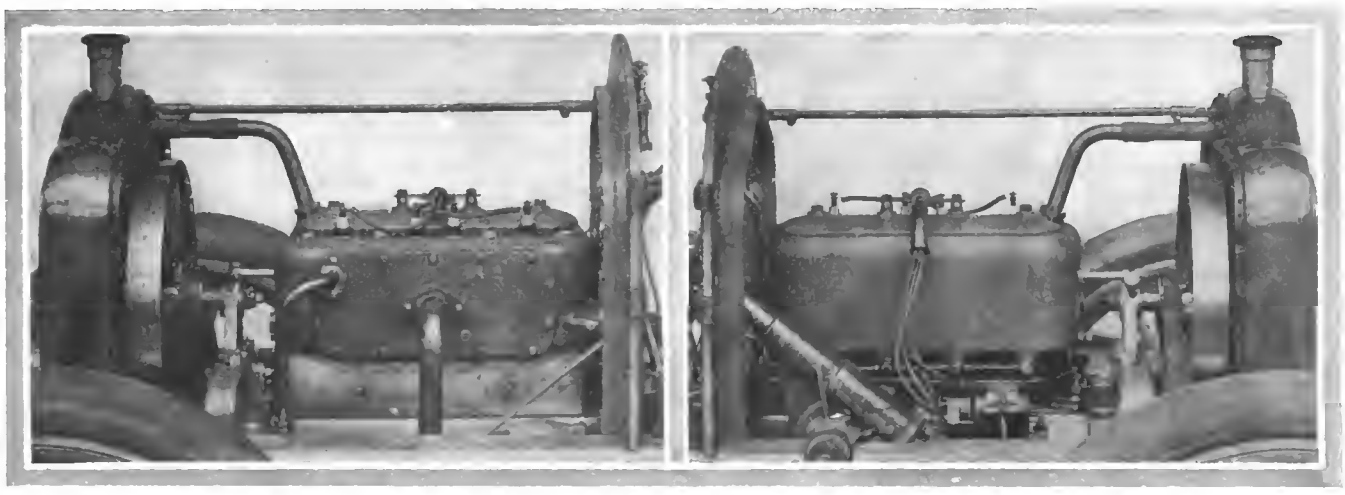
Features of Both Steam Models—In order to use kerosene as fuel no change has been made in the burner proper. The only modifications are in the vaporizer and in the shutter controlling the amount of air admitted to the burner. As in the case of many other great mechanical advances the desired end—in this case to use kerosene as fuel—is obtained by means which are surprisingly simple. As for the degree of success obtained by the designers of the White in adapting the car for the use of kerosene, it is only necessary to say that when the car is in operation it is practically impossible for any one to tell whether kerosene or gasoline is being used as fuel. When starting the car "cold" it takes about five minutes longer to heat the vaporizer sufficiently so that the main fuel supply may be turned on, but thereafter the action and operation of the car are the same as when gasoline is used as fuel. Only a few minutes are required to make the necessary adjustments to the vaporizer and to the shutter so that the fuel may be changed from kerosene to gasoline or vice versa.

The generator in both the Model "M-M" and Model "O-O" is of the usual White construction, consisting simply of nine coils of steel tubing so joined together that in operation water is supplied to the upper coil and steam issues from the lower coil. No change has been made in the regulating system, as this part of the car may be said to have been developed to a state of perfection; that is, the temperature and pressure of the steam remain practically constant without in any way engaging or requiring the attention of the driver, no matter what the running conditions may be.

The White Gasoline Car—With the addition of a gasoline car to the White products the extensive selling organization of the company is in a position to meet the demands for all classes of cars. In adding a gasoline car to its line at this time the White Company, with its factory facilities, long experience in automobile building and trained organization, unencumbered by any preconceived notions for or against any particular construction, is in a position to furnish the best in gasoline-car design, workmanship and material.

The White gasoline car is fitted with a four-cylinder, four-cycle engine of extremely simple and neat design. The car has a four-speed selective type transmission and a shaft drive. The four cylinders are cast in one piece. The cylinder dimensions are 3 3-4-inch bore and 5 1-8-inch stroke. The stroke is longer in proportion to the bore than in any other American car, the White construction being in accordance with the 1909-1910 practice of the leading foreign designers. The advantages claimed for the long stroke are much greater efficiency and higher fuel economy.

A feature of the car is the unusually small amount of piping and fittings under the bonnet. The valves are all on one side and are actuated by a single half-time shaft. The valve springs are not exposed to view, but may be inspected or replaced by removing a side plate.



The inlet side of motor shows simple piping — And the magnete side, too, looks clean cut

Left and Right Hand Views of the White Gasoline Block Type Long Stroke Motor

There is neither an inlet manifold, an exhaust manifold or a water manifold in sight. Fig. 4 shows the left-hand side of the engine on which side are located the valves and the spark plugs. At the front of the engine on this side is a centrifugal pump, from which a pipe leads to the water jacket. In the center is the intake pipe leading from the carbureter. From the rear of the engine the exhaust pipe leads to the muffler. The oil reservoir forms an integral part of the aluminum crankcase, being located at the rear on the left side.

As shown in Fig. 5, there is no piping except the oil leads on the right side of the engine. The only device on this side is the gear-driven Bosch magneto, to which the timer is attached. The only wiring on the car consists of the four short wires leading from the timer to the spark plugs, as shown in Fig. 5, and also the two wires leading to the switch on the dash. The crankshaft has but two main bearings which are annular ball bearings of generous dimensions. The connecting-rod bearings are of Parsons' white metal. The oil pump is driven from the half-time shaft and supplies oil to the connecting-rod bearings and to the crankcase by way of an adjustable sight-feed on the dash. The gears driving the half-time shaft, the water pump and the magneto are of fiber and metal and are completely inclosed. The radiator is of the "honey-comb" type and its shape follows approximately the lines of the condenser of the White Steamer.

The engine is attached to the cross-members of the frame by three-point suspension. The clutch is of the leather-faced cone type. The gear-case is hung by three-point suspension on the cross-members of the frame. As already mentioned, the transmission is of the selective type with four forward speeds and one reverse. The direct drive is on the third speed. The drive from the gear case to the rear axle is by means of a shaft fitted with two universal joints. The frame is of pressed steel, narrowed at the forward end. The wheel-base is 110 inches. The front axle is of I-beam section and all bearings on the wheels and in the rear axle are annular ball bearings.

INTENDS TO HAVE PERFECT COMMUTATORS

To repeat an old expression, there's many a slip betwixt the cup and the lip. This does not apply to automobile parts, but a perverted form of it might be made to do duty as a means of expressing the fact that the finished machine may lack something intended to be put on or in some way attended to. So, any device which has for its object the proving of correctness of a minor part of the machine is worthy of attention.

Device for Testing the Accuracy of Rambler Commutators

In the work of producing a vast number of machines as in the factory of Thomas B. Jeffery & Company, a little machine just perfected will save the future owner many a long search for the source of trouble. This is a commutator testing device, and is intended to prove up, previous to use, the condition of the timer. A gear with a contact arm and roller, corresponding to these parts on the commutator, is attached in the center of an indicator, upon which an arrow shows whether the timer is set to fire early, late, or correctly. By this means it is asserted absolute accuracy of timing is obtained.

71 ALARMS IN 136 DAYS; $24.81

GRAND RAPIDS, MICH., June 14—The value of the automobile fire engine was one of the principal subjects of discussion at the Michigan State Firemen's Convention, which has just been held in this city. Chief Charles Fishbeck of Alma read a paper favoring self-propelling machines, and in the discussion the advantage of the auto over the ordinary horse-drawn engine in climbing hills, on clay roads and unpaved streets was pointed out, and the saving of the expense of an extra hose cart for carrying hose. Chief Delfs, of Lansing, who has recently been furnished with an auto engine, reported that his engine had responded to 71 alarms in 136 days, a total of 16 hours at a total cost of $24.81.

A HANDY METRIC CONVERSION TABLE

The table here given is one circulated among engineers by the C. W. Hunt Company, of West New Brighton, N. Y., and in view of the manner in which it is compiled, it should be of good advantage to automobile engineers and others who are required to treat with metric measurements in conjunction with the English system. It is given below:

Millimetres × .03937 = inches.
Millimetres ÷ 25.4 = inches.
Centimetres × .3937 = inches.
Centimetres ÷ 2.54 = inches.
Metres × 39.37 = inches. (Act Congress.)
Metres × 3.281 = feet.
Metres × 1.094 = yards.
Kilometres × .621 = miles.
Kilometres ÷ 1.6093 = miles.
Kilometres × 3280.8693 = feet.
Square Millimetres × .00155 = square inches.
Square Millimetres ÷ 645.1 = square inches.
Square Centimetres × .155 = square inches.
Square Centimetres ÷ 6.451 = square inches.
Square Metres × 10.764 = square feet.
Square Kilometres × 247.1 = acres.
Hectare × 2.471 = acres.
Cubic Centimetres ÷ 16.383 = cubic inches.
Cubic Centimetres ÷ 3.69 = fl. drams (U.S.P.)
Cubic Centimetres ÷ 29.57 = fluid ounces (U.S.P.)
Cubic Metres × 35.315 = cubic feet.
Cubic Metres × 1.308 = cubic yards.
Cubic Metres × 264.2 = gallons (231. cubic inches).
Litres × 61.022 = cubic inches. (Act Congress.)
Litres × 33.84 = fluid ounces. (U. S. Phar.)
Litres × .2642 = gallons (231. cubic inches.)
Litres ÷ 3.78 = gallons (231. cubic inches).
Litres ÷ 28.316 = cubic feet.
Hectolitres × 3.531 = cubic feet.
Hectolitres × 2.84 = bushels (2150.42 cubic inches).
Hectolitres × .131 = cubic yards.
Hectolitres ÷ 26.42 = gallons (231. cubic inches).
Grammes × 15.432 = grains. (Act Congress).
Grammes ÷ 981. = dynes.
Grammes (water) ÷ 29.57 = fluid ounces.
Grammes ÷ 28.35 = ounces avoirdupois.
Grammes per cubic centimetre ÷ 27.7 = lbs. per cu. in.
Joule × .7373 = foot pounds.
Kilo-grammes × 2.2046 = pounds.
Kilo-grammes × 35.3 = ounces avoirdupois.
Kilo-grammes ÷ 907.2 = tons (2,000 pounds).
Kilo-grammes per sq. cent. × 14.223 = lbs. per sq. in.
Kilo-gram-metres × 7.233 = foot pounds.
Kilo-gramme per Metre × .672 pounds = lbs. per foot.
Kilo-gramme per Cubic Metre × .062 = lbs. per cu. ft.
Tonneau × 1.1023 = tons (2,000 pounds).
Kilo-Watts × 1.34 = Horsepower.
Watts ÷ 746. = Horsepower.
Watts × .7373 = foot pounds per second.
Calorie × 3.968 = B. T. U.
Cheval vapeur ÷ .9863 = Horsepower.
(Centigrade × 1.8) + 32 = degree Fahrenheit.
Franc × .193 = Dollars.
Gravity Paris = 980.94 centimetres per second.

CANADIAN PACIFIC RAILWAY ADOPTS AUTOS

MONTREAL, CAN., June 14—One of the latest innovations in modern railway work, the automobile hand car, has been adopted by the Canadian Pacific Railway. A number of these have been purchased and put into active service, one on each division, to be used for inspection work. The little cars, for they are so small and light that a few men can lift them onto or off of the track in time of necessity, will be useful for close inspecting work which the ordinary locomotive and car can not do.

Exhaust Side of Automobile Motors

By Thos. J. Fay

Part II

NOISE is the bane of the automobile, particularly the character of noise that emanates from the exhaust of a motor, and it is the function of a muffler to stifle the same. The efficiency of such a device cannot well be regarded as an abstract quantity on the ground that all motors do not perform in like manner as respects noise made. This is proven when a given muffler, which may be satisfactory on a given motor, fails to do good work on another motor of the same size.

It is even true that a given motor will act differently under changing conditions, and in a general way it may be said:

(A) Noise will swell in volume as the compression is increased.

(B) The combustion pressure will cause noise, increasing with the same.

(C) A belated spark will induce noise, due to the combustion continuing into the muffler.

(D) Noise will be present, increasing as the terminal pressure.

(E) Increasing speed will have the effect of increasing noise also.

(F) Noise increases as the volume or weight of the exhaust gas increases.

(G) Ill-devised parts, in which vibrations are at a rapid rate, will have a marked effect on the volume and character of the noise emitted.

To better understand the reasons why noise is made it will be profitable to go into the details of the phenomenon, rather with the expectation of being the more able to thwart the process and eliminate the noise.

Sound Is Not Produced In a Vacuum—Sound implies the vibration of air or some other medium; obviously, a vacuum, in which there is nothing to vibrate, will not support sound. Since sound implies vibrations, some of which may be classed as harmony and the balance as discordant (noise), the problem of the exhaust may be approached along lines taking into account the natural laws, in so far as they are applicable.

When a sound is perceived it is certain that some body, in one of its states of aggregation, is being vibrated; moreover, when a body is vibrated the air surrounding the same vibrates in unison, and the effect of the vibrating body on the surrounding air must be taken into account in any attempt to stifle the sound. The drum-skin of the ear, together with the bone members, vibrates in response to surrounding vibrations, and in this way we are rendered conscious of the vibrations which we call noise if they are out of harmony, and musical notes if they impress us favorably. Were all men deaf, it would be a matter of no moment at all as to the character of the vibrations made by the exhaust from motors, and no attention would be paid to this phase of the problem, excepting as the vibrations would affect the life of the parts or the amount of power available.

Acoustics, which is the branch of Natural Philosophy dealing with the vibrations that cause sound, must be regarded as the cause of the manifestations, while sound is a sensation peculiar to the ear; since deafness is not universal it becomes necessary to treat with the acoustics of the automobile in order to afford agreeable, if any sound, as it is emitted from the bowels of a car, and as experience dictates, the exhaust is a prolific source of the class of sound that is placed in the catalogue of noise.

The best results will follow if all vibrations are eliminated, and next to this, it is desirable to so control the vibrations, that the sound emitted will be feeble at best, and of a character such as can be borne with equanimity. The absolutely sure way to abort sound is to place the car in a hermetically sealed chamber and exhaust the air from the same; even then the car, at any part, must not contact with the chamber; this is not a practical way to proceed, but it does afford a fulcrum, as it were, on which to rest the lever of reasoning, rather with the expectation that the lever will multiply advantage and lift the reasoner to a higher and more satisfactory plane.

Since it is the ear that is affected by sound, and in view of the ease with which the same ear becomes unconscious of sounds that in the beginning are perfectly audible, it is easy enough to reason out how builders of cars persuade themselves into the belief that their products are as noiseless as the very depths of Nature in the still of the night, whereas others may be much impressed by the very noise emitted. In the delineation of noise (sound) then, there are phases of the problem that cannot well

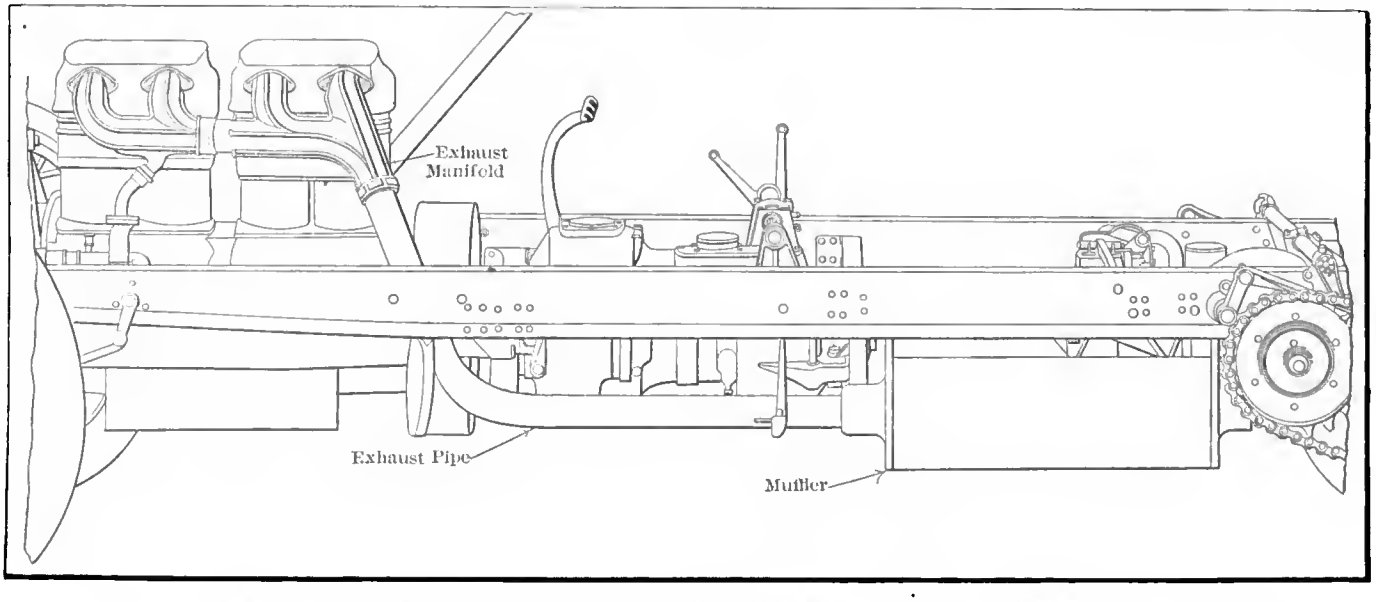


Fig. 61—Showing position of muffler, how the exhaust pipe passes along to the manifold, and easy bends at all points

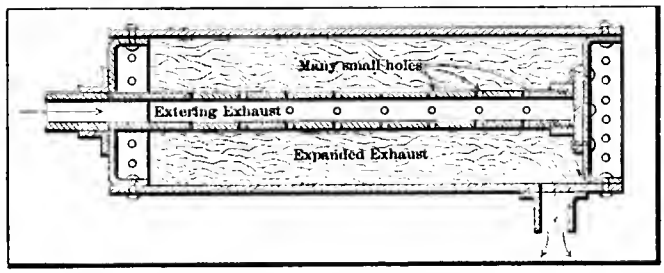

Fig. 62—Depicting a simple form of muffler, used on many cars, and delivering good satisfaction

be disposed of on the ground that what one person calls noise another would fail to notice.

Noiseless performance, then, is not always what it is presumed to be and in the discussion here it will be to the purpose to designate the same as "performance in the absence of any noise at all," such as would be audible from a prospect in the vicinity of the performing car to one who is not under the influence of the chloroforming influence due to long familiarity.

Sound travels at a constant velocity, no matter what may be the pitch, intensity and timber, which are the three prime qualities by which it is interpeted. By pitch, sound is located on a scale; thus we speak of sounds higher, or lower on the scale, and the higher the pitch the greater is the number of vibrations that produce it. The ordinary ear is sensitive to sounds that are produced by 40 vibrations per second, which low rate of vibration induces a sensation that resembles the beats of two base organ pipes if they are considerably out of tune. In the higher range of vibrations the average ear is unconscious of sound produced by 12,000 to 20,000 vibrations per second, and many are so "sound blind" that they are incapable of noticing the result of less than the minimum number (12,000) stated.

In America, Great Britain, and Germany, a vibration is taken to be a movement to, and fro, of the vibrating body. In France, a vibration is regarded as a motion to, or fro. This difference must be taken into account when the matter is under consideration.

Pitch rises with the number of vibrations, and may be determined in divers ways, as when a disc (of cardboard), perforated (in a suitable way), is rotated, and a glass tube, in juxtaposition, is blown through, and the disc is rotated at a uniform rate, simultaneously. The puffs of air resulting will emit a sound of increasing pitch, as the tube is moved out on the disc, under the influence of the rows of holes placed with an increasing radial relation, equi-distant from each other. Pitch then is under the influence of the physical shape of the member vibrated and the rate of vibration is the matter to be given consideration.

Intensity, as the word implies, relates to the energy of the air vibration which strikes the ear; hence the "amplitude" (extent of transverse vibration of the sounding body) may be measured, and in so doing it is possible to predict intensity, as it is affected by distance, in view of the law, which may be stated as follows:

The intensity of sound (like that of light) varies inversely as the square of the distance.

This question of intensity is of the greatest importance from the point of view of the muffler, which is the thing to be kept uppermost in the mind's eye during the course of this discussion. It was said that, in a vacuum, sounds cannot be propogated, for

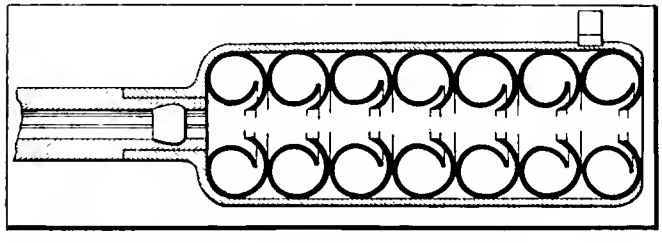

Fig. 63—Maxim's silencer, used on guns, but suitable for use in muffling work, in connection with automobiles

the reason that there is no matter to set into vibration; let us reason backwards, and to illustrate a point, go down into a caisson, in which the air pressure is as much as two atmospheres; under such conditions, even a whisper becomes a noise, and conversation at the ordinary (normal) intensity becomes painfully loud. Increasing the pressure of the atmosphere then has the effect of increasing the intensity of sound due to vibration, and in a muffler the pressure is increased over that of the atmosphere (by a considerable amount; to at least two atmospheres), so that the intensity of sound is the normal expectation. Then, account must be taken of pressure variations, and the differences in intensity that must follow in view of the increase in intensity for increasing pressure, which assures that the intensity will change with the pressure changes. In this way the intensity of sound becomes compound, as it were, and a classification becomes very difficult, excepting that it is a noise that will result, rather than a musical note; of that we have exact knowledge and not a few examples.

"A simple sound is one in which the ear can distinguish only one sound of one pitch." A tuning-fork, for illustration, emits a simple sound; composite sounds are the product of several simple sounds intermingled, as exemplified when a piano wire is struck, causing it to vibrate. In the instance of the piano wire, it is the practice to so locate the venters and nodes that

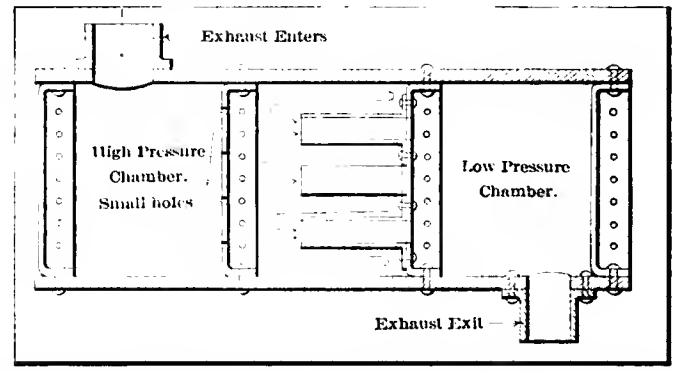

Fig. 64—Simplex type of muffler, showing three chambers, so contrived that the pressure is reduced almost to zero before the exhaust makes its exit to the atmosphere

sounds are as overtones in the harmonic relation; as when treble C (middle) is to 1:2:3:4:5:6:7:8 C, etc. The intermingling of the overtones, in such a case, will have for the lowest pitch, the treble C superimposing the higher harmonics.

"All simple sounds have the same timber." This property, referring to sound, is analogous to color in light; in sound, it is possible to change the timber by the simple expedient of mingling a different set of simple sounds, in a manner not unlike the changes that can be wrought in color, by altering the proportions of the pigments used. A chorus of components, however, may be in harmony, or it may not. In the case of the muffler, the chorus of sounds emitted is, as a rule, discordant.

The difference between harmony and discord is not so readily explained, although, as a musical proposition, we owe much to the work of Helmholz, and for the rest, perhaps in a practical way, to Prof. Mayer. As Helmholz pointed out, if light is taken as an illustration, and the number of flashes per second are at a low rate, the sensation is disagreeable; upon increasing the number per second the sensation changes, and when a certain rate is attained the eye then fails to perceive the spaces between flashes (the dark periods), and the disagreeable sensation is lost. In the same way, as it was pointed out, beats of sound show the same effect. When Prof. Mayer undertook to demonstrate the point to be made, he used disks perforated with various sizes of holes, which admitted and shut off the sound alternately, with the result that flashes of sound followed.

In this way Prof. Mayer was able to determine that the duration of sensation of sound depended upon the pitch of the same, and he also found that the higher the pitch the less the in-

terval of time. It has been determined that when resultant beats of sound from two sets of vibrations are intermingled the number of beats per second corresponding must be at a certain high rate or the sound will be of the character classed as noise. When a plurality of separate vibrating members are in sound relation, as in a muffler, it is difficult to see how, by deliberate design, the resultant can be sufficiently controlled to assure a musical sound; nor is it to be supposed that a muffler should be an imitation of a steam caliope.

What Practice Would Seem to Dictate—From what has been said involving the laws of sound, it would seem as if the one best way to fashion a muffler should take into account the intensity, pitch and timber of such sounds as are produced at the atmospheric pressure. So much for the functions of the muffler, which does not afford the right to design the same in such a way that the materials used will act as sounding-boards, bells, pipes, etc. Fig. 61 is offered as illustrating a system so contrived that the bends are easy, the materials so disposed that sounds emanating from them will be but feeble at best, and the parts are so supported to the chassis that they are not prone to go adrift, hence chattering will be avoided.

A simple exhaust silencer (muffler) is shown in Fig. 62, consisting of a cylinder and a pipe so contrived that the pipe, which is drilled full of small holes, will admit the exhaust at high pressure, and as it is required to pass through a large number of small holes, it is split up and then expanded. The gas passes to the atmosphere in an even flow, at a pressure slightly above that of the atmosphere. This type of muffler is fairly efficient when well designed, but as a more advanced type it is very likely that the Maxim silencer will do better work. This silencer is depicted in Fig. 63, which is a cross-section, and, as will be seen at a glance, the gas as it enters the silencer is swirled around the spiral-like cells and is minutely subdivided and fully expanded in the process, so that it emits from the silencer (when it is used on a gun, at any rate) with little or no noise or sound of any kind.

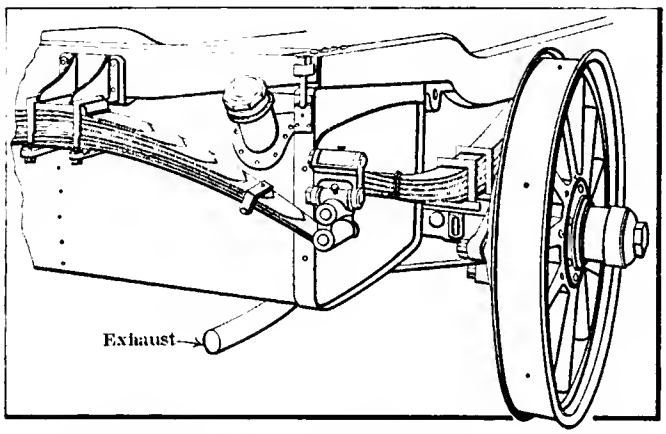

Fig. 65—Exhaust pipe passes under gasoline tank in rear, demanding that it be well secured to prevent whip-sawing

One of the most satisfactory types of muffler that the author has been able to experiment with is that as shown in Fig. 64, showing a cross-section of the "Simplex," from cars of the same name. In this type of muffler the exhaust enters a high-pressure chamber, and then passes through a separating wall filled with holes, 3-16 inch in diameter, of a combined area equal to that of a piston of the motor. The high-pressure chamber is designed with a cubical space equal to the displacement of one of the cylinders of the motor. The middle chamber of the muffler represents double the volume of one of the cylinders of the motor, and the tubes in the second dividing wall, of which there are five, have a combined area equal to that of an exhaust valve of the motor. The arrows show how the gases rush from the high-pressure chamber into the middle chamber, dash against the second wall, and, after bounding back, make their exit into the low-pressure chamber by way of the five relatively small tubes. The low-pressure chamber has a volume equal to that of the other two chambers combined, and that it should be more is probably true. The exhaust from the low-pressure chamber is in a little less than the period of four cycles, so that the space is available for the next inrush of gas after the completion of each four cycles. The illustration shows the cylinder with walls considerably thicker than practice dictates, although it is true that it is by way of noise reduction if the walls are thick.

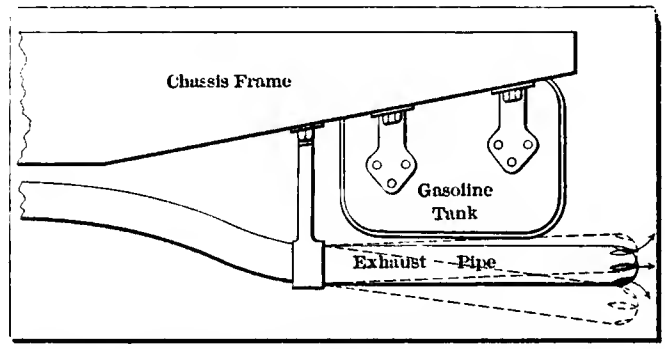

Fig. 66—Side view of constructions shown in preceding figure, and what happens if pipe is not well secured

Certain Design Features to be Considered—Besides the design of the muffler there is the question of the placing of the same. Fig. 61 shows the muffler in the fore-and-aft plans, in front of the rear axle; this is a very good location, and is the only one left when the gasoline tank is in the lateral plane to the back of the hind axle. Fig. 65 shows the gasoline tank to the rear, and the exhaust pipe passing under the same. Fig. 66 tells the balance of the story, provided the pipe is insecurely fastened, as it is in some cases; the end of the pipe whipsaws against the bottom of the gasoline tank, and it is but a matter of time when a hole will be the natural result in such a case.

Sometimes the muffler is placed to the rear of the chassis frame, in place of the gasoline tank, in the manner as depicted in Fig. 67, and a muffler cutout is located in the exhaust pipe just before it enters the muffler. That the muffler cutout should be well to the rear is assured, in view of the smell that is so prone to emanate from the exhaust, and locating the cutout at this point assures that the smell will be wafted away, with the hope that it will be of small inconvenience to the hindmost; the smell should be abandoned at the first way-station.

Sometimes the muffler is placed at the back in such a way that the exhaust pipe hangs from it and sags down, as shown in Fig. 68, so that there is an interference with the hind axle; this is a very serious matter, and it is only to be mended by suitably securing the exhaust pipe; incidentally, the muffler should be so fastened that it will stay in place and not rattle. The exhaust outlet may serve as a dust raiser, particularly if it is placed as shown in Fig. 69, with the end close to the road-bed and pointing at it. A better plan is offered in Fig. 67, and that the exit for the exhaust should be at the rear of the car is one of the points to be taken for granted.

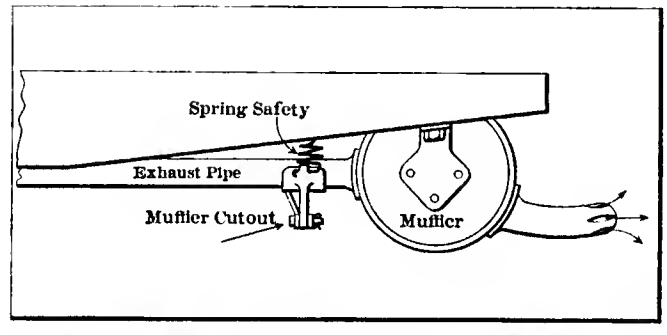

Fig. 67—Side view, showing muffler to rear of chassis, and muffler cut-out located so far back that exhaust will not float up into the car

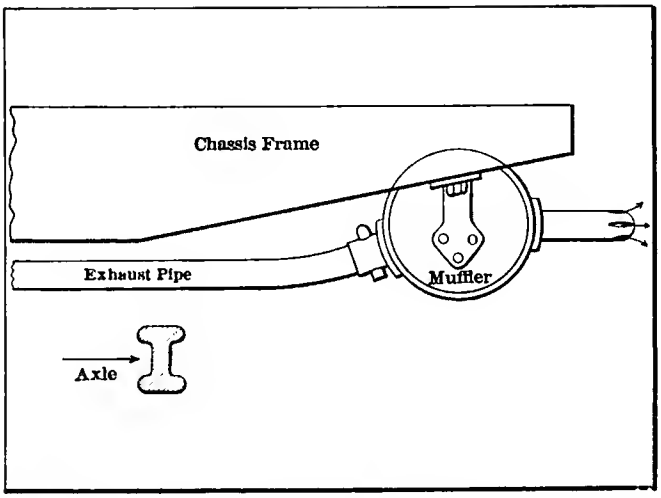

Fig. 68—Muffler located in rear and so weighed down by pipe that axle interference is imminent

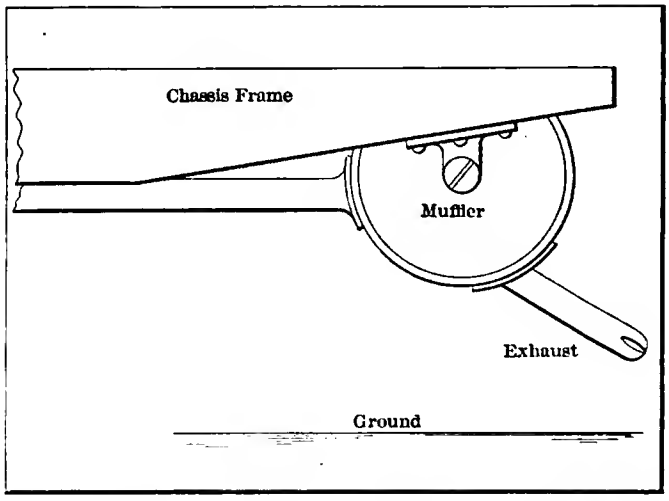

Fig. 69—Muffler in rear, and end of exhaust pipe pointed at the roadway, so near as to raise dust

In certain classes of work it is the custom to avoid the use of a muffler, on account of the back pressure that is likely to attend the use of any device provided for the purpose of aborting noise due to the exhaust. Fig. 70 shows a racing design in which no muffler is provided, and the exhaust is allowed to escape through direct openings on the side, not shown in the figure. In this connection it is well to point out that the design as shown in Fig. 64 is almost devoid of back pressure, and there are many examples of mufflers that do not offend to a serious extent in this direction. Before departing from the subject, especially as it relates to Fig. 70, it may not be out of place to emphasize the location of the gasoline tank, and the manner in which it is nested inside of the spare tires. In racing work, in particular, it is extremely difficult to keep the tank in place, and it is also a vain search betimes to find room for the spare tires; in this case the dual problem is neatly attended to. In conclusion, it will be enough to say that a little back pressure is better than much noise, and a muffler cutout will afford temporary relief, if it is found that the muffler does reduce the ability of the motor below the requirement on a hill.

Drop-Forged Steel Hangers Are Used—The time was when hangers of case gray iron were used to support mufflers and even the gasoline tank; experience has adequately proved that cast iron is of little or no value in this service, and the forgings of steel have to be of good quality if the work is to be regarded as of a permanent character. Nor can it be claimed that bronze castings are good enough to use, although it does seem as if steel forgings would have preference on the ground that they cost less, which is besides the question of their greater life in this class of work, not to mention the greater uniformity of material, absence of "wasters," and assurance of prompt delivery in quantity.

The work the hangers have to do does not look arduous when a car is standing on the floor of a garage, but on the road when cars are doing turns at some speed the side strains are well worth taking into account, and if they are not it is a fair inference that a repair bill will render itself manifest at an early date. The idea that castings are cheaper and that more material can be used is not a good one to follow up, for the increased weight placed on a chassis will make itself the basis of additional cost of springs, etc. The appearance is against such construction and that autoists would prefer to have cars in which castings are not used to support important parts is one of the matters that can be taken for granted.

If drop forgings are used they should have an adequate bearing against the sheet-metal ends of the muffler very much in the manner as shown in Fig. 68 rather than as depicted in Fig. 69 with good and secure riveting, so that the muffler will stay in place. The forgings should be of acid open-hearth steel, the composition of which may be as follows:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
0.20	0.10	0.04	0.04	0.40

If there is any difference the carbon might well be a little lower, say, 16 points, rather than to have it higher. The manganese might also be held a little lower than the value given.

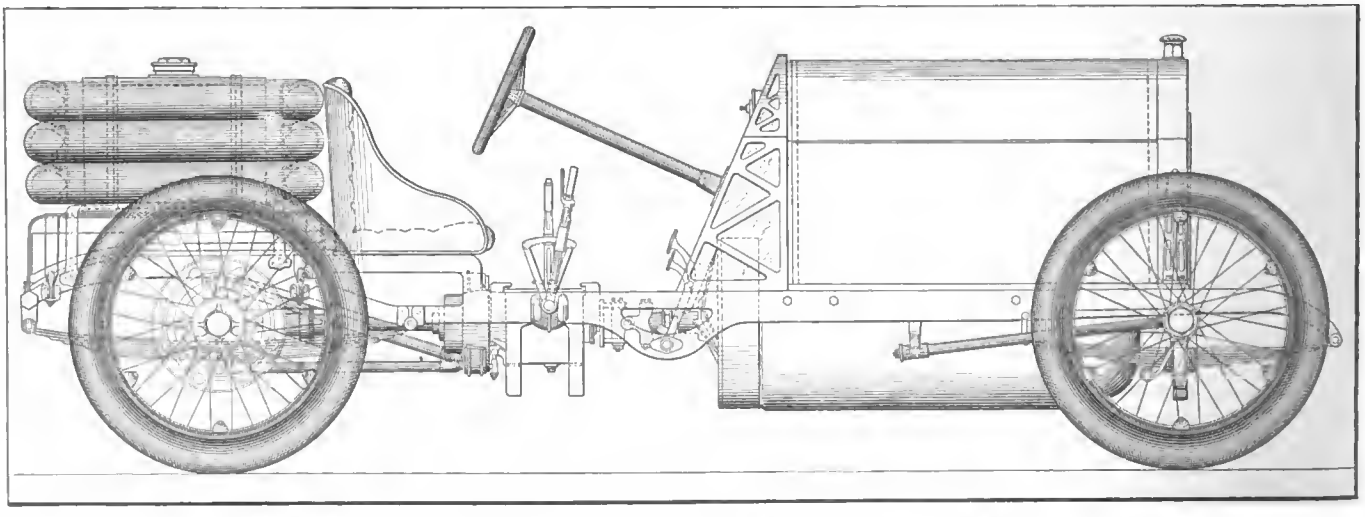

Fig. 70—Racing car design in which, to avoid back-pressure, no muffler is used; the same design shows a novel gasoline tank, and means for carrying spare tires

How New Drivers Can Reduce Tire Wear

By James S. Madison

AT this season of the year, many men and women are the proud possessors of their first automobiles. The car looks beautiful, the brass glitters, the varnish has a mirror-like surface, and the tires, in their attractive symmetry, seem indestructible and give no suggestion of the rapidity with which they will wear out, and no hint as to their capacity for trouble. Let the novice be assured that the time he will spend on keeping brass bright and the paint clean is out of all proportion to their value. He should realize in the beginning that it is far more important—in fact, most important—that he should give his tires his first, last and most intelligent attention. If he is a man of limited time and means, it would be more sensible and economical to neglect his brass until it resembles brass only remotely, than to neglect his tires.

The owner who does the latter, who fails to obtain all the information possible about the care of his tires, is inviting trouble, and will sooner or later pay a large price for his carelessness and ignorance. This information is not difficult to acquire; it is accessible to every one who will write to the tire manufacturer, asking for it. All the important manufacturers publish instruction booklets which they are glad to send to the user in the hope of enlisting his co-operation securing the best results.

The new owner should realize at the outset that the most expensive and the least permanent part of his entire equipment is the tires. He should make a simple calculation something like this: assuming that the tires will last for 3,500 miles and the cost of the new tires is $150, what is the tire-cost per mile? The answer is 4.3 cents. But this isn't all of it. With the most intelligent care, there will be punctures, gashes, sand blisters, with perhaps an occasional blow-out, rim cut, leaking valve, etc. These must be repaired; each repair will cost 35 cents or more at the garage, which will run his tire expense up to 6 or 8 cents per mile or even beyond that.

Of course, there are many tires that will give a mileage far in excess of this, but if the owner gets a greater amount of service, he should regard it as exceptional and be correspondingly thankful. He will be wise if he makes his calculation on the basis of the figure given. On the other hand, there are many tires that do not last as great a distance as this, due to improper care and driving on the new owner's part, rather than to defects in material or workmanship.

While it is true that the manufacturer will make an adjustment and supply new tires, in most instances at the consumer's price less the fixed and stated allowance for the mileage obtained from the old tires, yet this is usually a matter of great inconvenience, often resulting in the car being out of commission from several days to a week or more, depending upon the distance the owner lives from the factory.

There are a number of causes which induce the rapid deterioration of pneumatic tires. Of these, the two most important are: overloading and under-inflation.

How to Avoid Overloading—The novice asks "How am I to know whether my tires are overloaded?" There is only one way. Run the car on an accurate platform scale, and weigh it. Do not trust other people's statements as to the weight. They are sometimes false. The writer is familiar with a car that was described in the catalogue as weighing "approximately 1,650 pounds." The scales showed 2,000 pounds. The owner, in ignorance of the effect on his tires, added to his car a speedometer, an odometer, a clock, a heavy top with front, side and storm curtains, a complete line of tools, a heavy jack, a pump, extra parts, extra tubes, a tire repair kit, etc., so that with two passengers of average weight his tires were supporting 2,400 pounds! The size of the tire with which the car was equipped was designed to carry 1,800 pounds. The result was inevitable. His tires began to be troublesome when he had ridden 1,500 miles. By constant attention and spending much time in repairing, he worried along with them until the total mileage was 2,400, when the entire set was done for, and was sold as junk. Had he weighed the car at first, he would probably have been more cautious in making additions to it, and would have been saved continued annoyance and expense.

The following table, compiled from tire manufacturers' data, is intended as a guide to the novice. It gives the maximum weight each tires is intended to carry without being overloaded. These figures do *not* include the weight of the passengers:

Size of Tire	Weight per Wheel
2½ inch	225 lbs.
3 "	350 "
28 x 3½ "	400 "
30 x 3½ "	450 "
32 x 3½ "	550 "
34 x 3½ "	600 "
36 x 3½ "	600 "
30 x 4 "	550 "
31 x 4 "	600 "
32 x 4 "	650 "
34 x 4 "	700 "
36 x 4 "	750 "
32 x 4½ "	700 "
34 x 4½ "	800 "
36 x 4½ "	900 "
5 "	1,000 "

These figures are given only as suggestions; the owner should not rely upon them wholly, but should get the data direct from the manufacturer. Should he find that his tires are overloaded and that he is unable to reduce the weight of his car sufficiently by removing superfluous articles, he must make up his mind to get the greatest mileage from the tires, and then replace them by a larger size. This may be accomplished easily without going to larger wheels.

Many of the tire manufacturers are now offering for sale the so-called "odd sizes." They are made so that a 30x4" tire will fit perfectly a 30x3 1-2" wheel, or if a larger size is desired, a 31x4" tire may be placed on a 30x3 1-2" wheel. Other "odd sizes" may be obtained.

Under-Inflation Is Equally Dangerous—It is difficult, if not impossible, for the beginner to know just what is the proper amount of inflation for the tires, until he has gained a certain amount of experience that is necessary. One may easily make the mistake of not giving the tires sufficient inflation. By far the greater portion of tire injuries is due to this cause. On the other hand, it is easy to go beyond the proper point and give them excessive inflation. The result of the latter error is generally not long in coming, producing, in many cases, an explosion of the inner tube and casing simultaneously, which means complete destruction of both.

All books of instruction advise that the tires be kept pumped up until they will stand up round under a full load, but the difficulty often comes in knowing just when to stop pumping. One motorist, in inflating, keeps pumping until the tires, when struck with a hammer, give out a certain characteristic sound. Another one kicks them until they show a certain resistance. These are crude and dangerous methods.

The evils of under-inflation are much more numerous than those of over-inflation, although, as a rule, they do not show themselves so soon after an injury has been done. When the tire is soft from insufficient air pressure, the rubber is much more liable to be cut or gashed by every stone or other sharp-edged obstacle it meets. Even if there be no actual cuts or punctures, the fabric will be injured by being subjected to the great pressure momentarily brought upon a certain portion of it by striking an obstacle. Although no obstacles may be struck, the fabric will be injured, nevertheless, by the constant bending to

which it is subjected. This tends to break the fabric and separate the rubber from it. It is inevitable that such injuries, while not apparent at the time they are received, will result later in a blow-out. The beads of the tires will be cut, if the tire is soft, and punctures will be more frequent.

The Beginner's Safest Way—One safe method for the beginner to adopt is to have the agent or some experienced friend look at his tires every day until he himself can tell by the appearance and feel that he has the right inflation. The best way is the use of a pressure gauge.

Since different makes of tires of the same size require different pressures, the figures below are intended only as suggestive:

Tires	Pressure
2½ inch	45-50 pounds
3 "	50-60 "
3½ "	60-70 "
4 "	70-80 "
4½ "	80-90 "
5 "	90-100 "
5½ "	100-110 "
6 "	110-120 "

To learn the pressure in the tire at any time it is only necessary to unscrew the dust cap and the inner cap of the valve stem of the tire and attach the register, when the pressure is at once indicated by a pointer moving over a gradual dial. One of the popular forms of gauges can be attached to the pump and valve stem at the same time; the air that is pumped in passes through the gauge which shows the pressure at the end of each pump stroke. Another form can be attached to the valve stem only. If the reading shows under-inflation, the gauge must be unscrewed before the pump can be attached. It may be necessary to repeat this manipulation several times before the tire is properly inflated.

Whatever the type of gauge employed, it should never be used until it has been compared with the reading of a standard gauge. A similar comparison should be made at frequent intervals. In this way only can one be certain that if he wishes 70 pounds pressure he does not get 80 or more, due to incorrect registering. It is not uncommon to find that the small gauges read from 10 pounds under to 15 pounds over the correct amount.

A Sad Experience with an Incorrect Gauge—Recently, a friend of the writer pumped up his old tires to 70 pounds, as recommended, determining the pressure with a new gauge. During the night, when the car was standing idle in the garage, one of the rear tires exploded, ruining the casing. On comparing the gauge next day with a standard, he discovered that it read 15 pounds too low. This bit of information cost him $25.

New tires should be examined every day for a week or more to see that the proper pressure is maintained, because the casing stretches slightly for about that length of time before it finally reaches the normal size under actual running conditions.

After the novice has provided means to guard against over- and under-inflation, he must always bear in mind that there are a number of other causes that may injure his tires. He will find it an advantage after every trip to run his hand over the entire surface of each tire for the detection of any possible nails, tacks, and wire ends, which may have been picked up and imbedded in the rubber. This precaution will save him many punctures.

He should at frequent intervals examine the entire surface of each casing for small cuts or gashes; if they penetrate the rubber through to the canvas (fabric) they should be vulcanized at once. Every particle of dust, sand or water that forces its way into an opening of this kind will damage the tire and shorten its life. If by accident grease or oil should get on the tires, it should be removed with a rag or waste moistened with a little gasoline. The owner should be sure, especially when the car is being washed, that none of the water gets into the inside of the casings. Moisture weakens the canvas which will finally rot, with the inevitable result—a blow-out. It will also cause the rims and side rings (in detachable tires) to rust.

Method of Procedure in Hot Weather—During the hot days of summer, the car should never be left standing in the direct sunlight. Whether the car is to stand for a short or a long period, a shady spot should be selected. In addition to the destructive action of sunlight on the rubber, the heat causes the air to expand, producing a greater internal pressure, and increasing the tendency to rupture.

On a hot day, the tires should not be pumped up as hard as they are during cooler weather. The rear tires are subjected to greater strains than the front ones, and begin to show the wear first. When this happens, it is advisable to interchange them with the front ones, and thus equalize the wear. Should a tire become deflated while in motion, the effects on the car are of such a character as to be clearly distinguished. If it is one of the front tires, the driver will at once experience difficulty in steering; if it is one of the rear's, the car acts as if it were being held back, or going over a soft or "greasy" piece of road. The sooner the car is stopped under these conditions, the better.

The car should never be run on a deflated tire even for a short distance, for, in a great majority of cases, the shoe will be ruined. Less damage will be done by removing the tire and running cautiously on the rim of the wheel. This, however, should be resorted to only in great emergencies. It is a better plan to wrap a piece of rope around the rim and felloe until the former is well covered.

Much damage to the tires is often unconsciously occasioned by the method of starting and stopping the car. Every time the car is started too suddenly, every time the gear change is made with a jerk, and every time the brake is applied too rapidly, the life of the tire is shortened a definite amount. Many drivers wishing to make a stop do not decrease the speed until within a short distance of the stopping-place, when they throw out the clutch and jam on the brake, making a very pretty stop in a few feet. This is a mild variety of grand stand play, but the driver who does it is taking life out of his tires every time.

Easy on the Corners Means Easy on the Tires—The period at which the very greatest strain is put on any tire is when it is rounding a corner at high speed, which is another excellent way to cut the life of a tire in half. The prudent driver will always turn a corner cautiously and slowly.

Tires frequently become very much heated during a long run. In many cases the heating is due not only to the natural friction between the rubber and the inequalities of the road bed, but also between the inner tube and casing. This may be largely eliminated by rubbing a good quality of finely pulverized talc on the canvas of the casing and over the inner tube before it is inflated. Should the tires become very warm, it is advisable to stop and allow them to cool.

Avoid running in street car tracks—they were intended for wheels made of iron, not rubber. Every owner should purchase as part of his regular equipment a vulcanizer, as he will thus be able to make his own repairs and save the expense, delay and annoyance of taking his car to the garage every time he finds a cut or puncture. The method of procedure is so simple that anyone may learn it in a few minutes. In the course of a year, the owner will save the cost of the vulcanizer several times over.

When on the road for a short trip, one should carry an extra shoe and two extra tubes; or if he does not wish to go to the expense of the shoe, one or two blow-out sleeves will usually see him through. In addition, he should always carry a jack, pump, some tire-tape, rubber cement, rubber patches, talcum, extra valves for the valve stem, and washers.

A Smoking Tip—Automobilists planning tours into France will do well to note a new rule laid down by the Director of the French Customs Office, applicable to those who smoke. After May 1 tourists will be allowed to take with them only half the amount of tobacco formerly permitted for personal consumption. Ten cigars, twenty cigarettes, an ounce and a half of tobacco, is the limit, and the tourist must choose one of the three, and not all three. Moreover, the Director refuses to recognize the right of a woman to smoke, and they will be unable to aid their male companions by carrying extra supplies.

LETTERS INTERESTING AND INSTRUCTIVE

GAS ENGINE IGNITION

Editor THE AUTOMOBILE:

[1,914]—Will you kindly tell me in "Letters Interesting and Instructive" if the current from a small dynamo could be used for ignition on a large gas engine, and if so, how should it be arranged? H. Y. Z.
Joplin, Mo.

You give so little information about the dynamo that the question is a hard one to answer. The ordinary current generator gives too low a voltage and at too high an amperage. If your voltage and amperage were correct, the addition of a spark coil or Rhumkorff coil, as it used to be called, and a timing device, would give a spark that would run the engine in a satisfactory manner. The ordinary magneto producing a true low tension current, which is intensified by means of a spark coil, gives about 35 volts at less than one ampere. If this be taken at exactly one to allow of some figures on the subject, the coil output will be, disregarding losses, say 20,000 volts at .15 ampere. This is upon two assumptions, namely, that the dynamo is a direct current machine, and that the field is separately excited, at least for starting. The latter statement is plain, if you consider that for starting purposes with a self-excited machine, a spark sufficient to ignite a charge is practically impossible, because of the very slow speed (comparatively) at which the operator can turn the engine over, with the consequent slow speed at which the current would begin to build up.

Next, as to the exact time of the spark produced by the outfit, if the engine does not already include such an apparatus, you will have to construct one yourself. To be exact, the current supply must be interrupted just before the point in the stroke at which the spark is desired in the cylinder. This might be done by purchasing an ordinary timer on the market, and rigging it up on the machine so that the speed is correct for the engine in question. This will differ with the number of cylinders, whether one, two, or more, and also, upon the cycle of action, that is, whether two or four cycle.

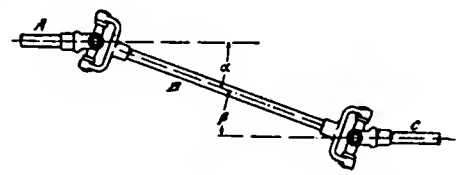
UNIVERSAL JOINT TROUBLE

Editor THE AUTOMOBILE:

[1,915]—Does a universal joint give uniform rotation at the rear axle? My car has double universal joints, and recently when the rear axle was removed and replaced, the slip joint was given a quarter turn in relation to the forward joint. Now with it in use, I fancy that I detect a surging effect in climbing hills on the second gear. Was not this matter discussed in one of the recent numbers of "The Automobile," and if so, in which one? B. S. H.
New York City.

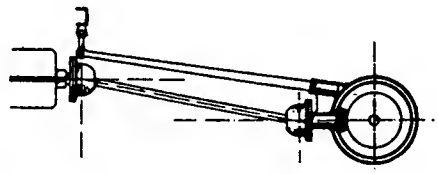
The surging which you mention would not be caused by the quarter turn which the rear joint was given, as this ought not to affect the relative rotation at all. If there was a noticeable surging effect, that is, if you are sure that you detected one, it must be due to wear in some of the universal joint pins, this resulting in a lag and then a consequent surging forward to take up the lag.

A paper on the Limitations of the Universal Joint was read by H. Vanderbeek at the September, 1908, meeting of the Society of Automobile Engineers, and reprinted in the October 8, 1908, issue of THE AUTOMOBILE, beginning on page 501. The point is made herein that the proper



Correct Arrangement of Joints

placing of two universal joints at the two extremities of a sloping shaft mutually correct the inequalities of each of the joints used singly. This proper placing amounts only to making the angle of the two shafts at the upper end exactly equal to the angle between the two shafts at the lower end, which is shown in the figure reproduced herewith. In this figure, the two angles which must be made equal are marked α and β respectively. As ordinarily applied to an automobile, this takes the form shown in the second figure, which, on close inspection, is seen to be exactly like



Same Form as Applied to a Car

the first one. The point not brought out above, but assumed, is that the three shafts are in the same vertical plane. If this is not true, none of the above holds good.

You will also find something of interest on this same subject contained in the paper Transmission of Power from Engine to Road Wheels, by L. A. Legros, in the May 13 issue of THE AUTOMOBILE. In this paper, on page 782, under the heading of Propeller Shafts and Bevel Gears, the author discusses the subject of universal joints, or, as he calls them, Hooke's joints, very thoroughly. The writer brings out the excellent point that the combination of two joints, one at each end of the propeller shaft, necessitates the use of torque rods, which is not the case with one joint.

POWER WITH TWO SPARKS

Editor THE AUTOMOBILE:

[1,916]—Will you please advise me on the following point? I have a four-cylinder car with double ignition. Now, would I gain anything by wiring the two plugs in the cylinders together, that is, would a spark at two points in the combustion chamber give more power than at present, or would it tend to make trouble in some other way?
New York City. H. S. B.

If you mean, would two sparks occurring simultaneously, increase the power, there is no question about it, the power would be increased. If you are able to so time the two sparking devices that the sparks occur at exactly the same instant, the power will be increased by an amount equal to about 15 per cent.

The reason for this is that the speed of propagation of the flame is much greater with two sparks advancing from two different sources toward a common center than would be the case with a single source from which the flame advanced to the center, and then beyond to the other side of the combustion chamber, and finally back to the center again. This, of course, is dealing in infinitesimals, but the effect is very marked. In last week's issue of THE AUTOMOBILE an article was given in which this subject was discussed very thoroughly, the result being, in that case, namely, on a four-cylinder Clement-Talbot engine of 85 mm. bore by 120 mm. stroke running at 1,100 revolutions per minute, the indicated horsepower was 18.4 using but one spark plug, and 20.8 using two plugs, a gain of 13 per cent. At a higher speed of 1,600 revolutions, the increase due to the use of the extra plug was practically the same in percentage, although in actual amount added it was more, the figures being 26.0 with one and 29.3 with two plugs.

The increase in power required to furnish two sparks is negligible, so that the only source of trouble is the exact timing necessary in order to get the beneficial effect. This being a mere matter of mechanical detail and requiring but patience to correct, may be dismissed with a word. If the increase in power with two spark plugs does not materalize, look to the timing and keep on looking until the latter is perfected, when the desired result will be forthcoming.

MAKE AND BREAK ACTS FUNNY

Editor THE AUTOMOBILE:

[1,917]—Will you please explain the following trouble which I have had lately with my make and break igniters. I took them all out, and after cleaning, put them back as per instructions with a 3-16 space between the hammers and the plugs. When the engine was started, it would run, but missed badly on a retarded spark. The throttle had no effect upon the missing, whether advanced or retarded. One-half or more advance of the spark and the engine would run fine. The most puzzling thing about it was the

fact that with three cylinders cut out, the engine which had previously refused to fire, would fire and run in the best of shape on the one cylinder remaining, even with the spark retarded. G. S. H.
Buffalo, N. Y.

The two statements are rather conflicting, that the engine missed badly on a retarded spark with all four cylinders, and ran fine with spark retarded on but one cylinder, so lay that aside.

Your source of trouble evidently lies in the igniters themselves, as nothing is said about the source of current beyond the statement that under certain conditions the engine runs fine, which presupposes a good source of current. Now, it would appear that the igniters were badly worn so that the distance advocated by the manufacturers and correct when the car was new, no longer held good. Therefore, you should set the points closer to the hammer than the directions call for, but your last statement would seem to indicate that all of them had not worn alike, one being still in good condition.

The proper method of procedure in a case of this sort, in which you have a good current supply, and apparently no other trouble than bad timing, as your statement indicates, is to put one cylinder on the firing point in the stroke, and then adjust your spaces until that cylinder fires. Having fixed one cylinder, adjust the other spaces to the same distance as was correct for the first case. If the igniters have worn equally, as is usually the case, this will allow all cylinders to fire correctly. If not, the wear has varied and each cylinder will have a separate adjustment.

Another source of trouble in a low-tension ignition system using make and break is the spring tension, and although this did not bother you this time, it is well to remember in future cases.

CRANKSHAFT SIZES AGAIN

Editor THE AUTOMOBILE:

[1,918]—Being a designer of automobiles and greatly interested in the letter (1881) in the May 13 issue of "The Automobile," I will ask you to repeat the formula given there and explain what the letters used therein represent. S. L. HEILMAN.
Boyertown, Pa.

The formula given in the issue mentioned was given under protest, as we deprecate the use of empirical formulæ, particularly in such places as the crankshaft. However, the two requested are here repeated.

For a five-bearing shaft:

$$\text{the crank pin diameter} = \sqrt[4]{\frac{P^2}{43.4\ S}}$$

and for a three-bearing shaft:

$$\text{the crank pin diameter} = \sqrt[4]{\frac{P^2}{37.5\ S}}$$

in which:

P = the maximum total pressure, which will always be the explosion pressure.

S = the tensile strength of the material used, in pounds per square inch.

CAUSE OF A BAD KNOCK

Editor THE AUTOMOBILE:

[1,919]—Will you please help me to solve a very puzzling case of knocking? My engine is a four-cylinder water-cooled machine of 15-horsepower. When put away last fall it was working well. After six months' idleness, it now develops a bad knock up hill which can only be eliminated by retarding the spark, but when that is done, the engine dies. The effect is the same on level ground if the throttle is opened more than one-third. Would the level of the gasoline in the carbureter have this effect, as I may have disarranged it while cleaning the machine. I have tried more air, less air, more gasoline, and less gasoline, but all without avail.
Somerville, Mass. SPARK GAP.

The effect of change of jet elevation, that is, change in the height of the spray nozzle, was fully discussed in letter No. 1,876 of the May 13 issue of THE AUTOMOBILE. The point there brought out seems to apply to your case, and thus indicate a cure for your trouble, so it is quoted here: "By raising the spray nozzle, you lower the level of the gasoline relatively. Therefore, the liquid will be less sensitive to the suction, which would reduce the amount of gasoline used. At low speeds, there would be a tendeney *to starve the engine, which would also be noticeable on hills.*"

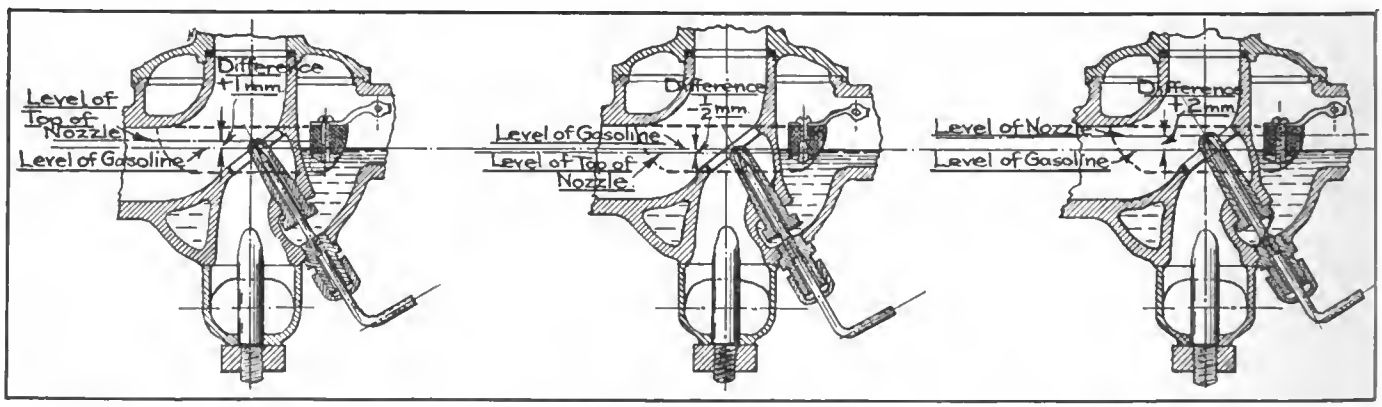
The italies bring out the point, and we think show you what the trouble is, namely, that you have inadvertently lowered the spray nozzle so that the engine does not get enough fuel at slow speeds and on hills. By raising this a small amount, the engine will be able to suck up more fuel and you will find that the trouble ceases with the change. In making this, be careful not to lower the nozzle too much at once, as the effect then is just as bad, the carbureter flooding at the slightest provocation. The better way would be to lower the nozzle a very slight amount, say one-quarter of a millimeter, or perhaps one sixty-fourth inch would not be too much. Try this level out very thoroughly, and when you are satisfied that it is not right, alter the level once more. The experience that you will get during the process will be worth all the time taken up in the series of successive adjustments, instead of trying to arrive at the result in a single or possibly two adjustments.

MANUFACTURER'S OPPORTUNITY

Editor THE AUTOMOBILE:

[1,920]—Kindly give me the addresses of all the manufacturing concerns engaged in the manufacture and sale of gasoline motor cars to operate on railroads, tramways, and industrial steel tracks for every purpose whatever. G. POWERS.
Queretaro, Estado de Queretaro, Mexico.

It will be necessary to make two lists in answer to this request, as many makers of cars for tramways and industrial tracks do not make railroad cars.



Correct nozzle position — Low location causes flooding — High position starves engine

Section of Typical Carbureter Showing Variations in Nozzle Level

Manufacturers of gasoline railroad cars:

Union Pacific Railroad Company, Omaha, Neb.
McKeen Motor Car Company, Omaha, Neb.
Sheffield Car Company, Three Rivers, Mich.
Buda Foundry & Machine Company, Chicago, Ill.
Milwaukee Gasoline Locomotive Company, Milwaukee, Wis.
Termatt & Monahan Company, Oshkosh, Wis.
Stover Carriage Company, Rockford, Ill.
Strang Gas Electric Car Company, Hoboken, N. J.

Makers of other gasoline-driven cars:

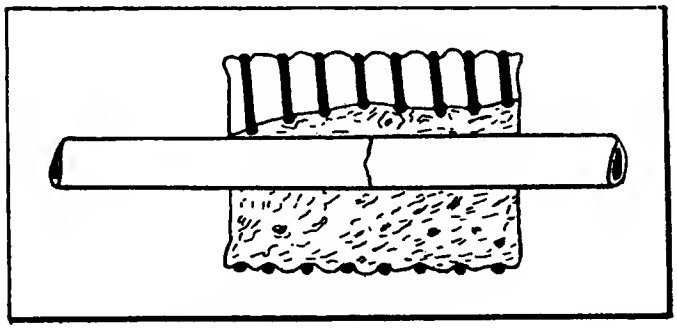
Sheffield Car Company, Three Rivers, Mich.
Empire Manufacturing Company, Quincy, Ill.
Jeffrey Manufacturing Company, Columbus, O.
Buda Foundry & Machine Company, Chicago, Ill.
Avery Company, Peoria, Ill.
Youngstown Car Manufacturing Company, Youngstown, O.
Arthur Koppel Company, Pittsburg, Pa.

There may be many other firms in this line which we have missed, but for their benefit the inquirer's address is given in full, and they are at liberty to write to this party direct. Similarly, if any firms have been included by mistake, this was done with the best of intentions, the inquiry as a whole being somewhat out of our line.

WHAT TO DO WHEN THE FUEL PIPE BREAKS

By D. R. HOBART.

BREAKS in the fuel pipe are responsible for a large proportion of fires that occur on automobiles, by reason of the escaping gasoline being ignited by contact with a hot exhaust pipe or by means of an electric spark due to a short circuit of the ignition current. If the autoist is not provided with a soldering kit and a garage or plumber is not within reach, ordinarily he must submit to the ignominy of being towed. On the other hand, there are a number of ways of temporarily repairing the broken pipe



Fuel Pipe Effectively Repaired with Cork

which involve common objects in connection with the spares ordinarily carried, and by employing one of these the delay inevitable to the breaking of the pipe will be shortened and the car can proceed to where a permanent repair may be made.

While the stopping of the leakage in a broken pipe is important, the main object of the repair is to continue the supply of fuel to the carbureter. The broken ends must be held together in order to accomplish this, and short of brazing the pipe, there are three methods which can be used to hold it temporarily. These are: the splint, in which the ends are held by splints in the same manner as in surgery; the jacket, in which a wooden or other jacket is employed; and the "wrapping" method, where the ends are retained in place by tire tape or metal. In effecting any of the following repairs, the fuel should be shut off, and if any heating is to be done, the pipe should be removed.

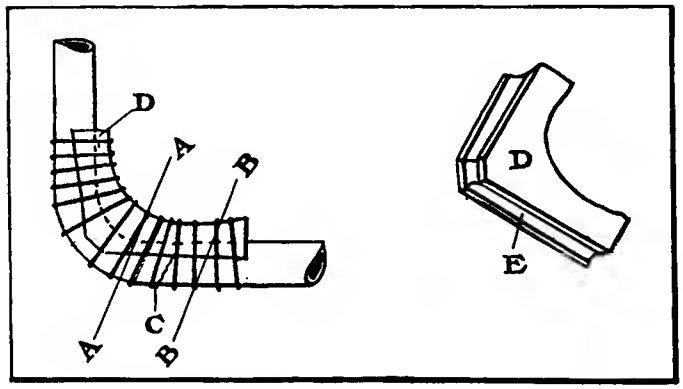
Repairing by the Splint Method—Where the break in the pipe occurs in a straight portion of its length, the broken ends may be retained in their proper relation to each other by means of splints cut from a lead pencil or some other convenient source, the operation being conducted as follows: The broken ends are well soaped and placed together and the splints put on, steel or copper wire being wrapped around the splints as tightly as possible with the pliers. A wrapping of tire tape should be put over the whole as a further precaution. This repair will be effective for cars using either gravity or low-pressure fuel feed, but in the latter case, care will have to be taken in driving.

While a splint repair will hold for a considerable length of time, it is not so permanent as one made by the "jacket" method, in which the broken ends of the pipe are held in place by a wooden or rubber jacket, either shrunk on or fastened by means of wire or cord. A repair by this method, which employs inexpensive and readily obtainable materials—an ordinary cork and some copper wire—will be practically permanent, and is effected as follows: Having obtained a cork of sufficiently large size, a hole the size of the pipe is cut in it. The broken ends of the pipe are well soaped and the cork pushed over them so that the ends are supported as in the sketch. Wire is next wound tightly around the cork, and the latter is then thoroughly impregnated with water. As a result, the cork swells and grips the pipe tightly. In preparing the cork, the cutting will be rendered easier if the knife or chisel is kept moistened with water from time to time. Outside of excessive heat, the cork will stand any kind of treatment to which the pipe may be subjected.

Shrinking On a Tube Over the Break—Another means of repairing the broken pipe is to shrink a piece of tubing over it. On the majority of automobiles, the fuel pipe is standard one-quarter inch pipe size, but plumbers and hardware dealers have copper tubing which is designated by the outside diameter instead of the nominal inside diameter, as is the case with standard sizes. The standard one-quarter inch pipe measures .405 inch on its outside diameter, while the one-half inch outside diameter pipe measures .402 inch on its internal diameter. By properly heating the latter pipe, it can be expanded until it is sufficiently large to be placed over the former, and when cool will contract and firmly grip it, the two pipes forming practically one piece. The procedure in shrinking on the pipe is as follows: the broken pipe is first cleaned and kept free from dirt by wrapping in a cloth. The half-inch pipe should be annealed by heating to a red color and then suddenly cooling in water. In this respect copper is different from iron and steel, as these latter are annealed by heating and allowing them to cool slowly. When the tube has been annealed it is heated to about 700 degrees, when it will expand sufficiently to be slipped on over the pipe. The wrappings are now removed from the pipe and the tube slipped over it and allowed to cool slowly, when it will grip the pipe. The autoist can replace the pipe and go on his way confident that the break will not occur again at that point.

When the Break Occurs Near a Bend—When the break occurs near a bend in the pipe, the repair is best made by a splint or block grooved to fit the pipe and fastened in place by wire. In the sketch, the break is shown at C and the grooved block D is shown in position attached to the pipe. The groove E is easily cut with a knife and should approximate the shape of the bend. If the pipe does not fit exactly, bits of tire tape should be put around it to assist in holding. After the wire has been applied, a final wrapping of tire tape should be put on around the portion AA-BB. The back of the block should be concaved, so that the wire will not work off the ends. A similar arrangement can be made when the break occurs in the bend.

Temporary Repairs to Breaks in Unions—Ordinarily a break in a union occurs close to the male connection, with the result that the released pipe springs away from the joint and cannot be retained in its proper position again with reference to the connection without soldering. For a temporary repair, the



Repairing Break Near Bend with Wood Splint

male connection should be removed from the union and the pipe wrapped with twine or tire tape close to the break. The broken end should then be thrust into the female connection as far as it will go and the union nut screwed up tight, expanding the tape or twine which will grip the pipe and prevent it from coming away for a short time. Copper wire can be used when neither tape nor twine are available, but the latter are to be preferred as giving better grip than the wire.

Two Repairs by the Wrapping Method—Occasionally the broken ends of the pipe will stay in their proper relation to one another when a wrapping of tire tape is applied, without the use of splints, etc. When tape is put on it should be wound as tightly as possible and reversed at intervals like a surgical bandage, so that the pull of both ends of the pipe will come on all portions of the tape. A more permanent repair by the wrapping method consists in tinning the pipe for some distance in both directions from the break and wrapping a ribbon of copper or brass spirally over the tinned portions, reversing the ribbon at intervals as when using tire tape. This necessitates the employment of a soldering iron or some substitute therefor.

An Easily Constructed Roadside Forge—When soldering is to be done and a blow torch is not at hand, the autoist can construct a "forge" from the dirt on the road, making a circular mound, say about eight inches high and a foot in diameter, saturating this with gasoline and setting it on fire. The soldering iron can be heated in this dirt "forge" just as well as in an ordinary shop forge, and the fire will continue to burn for a surprisingly long time. In making up a fire such as the above, care should be taken to locate it at the side of the road in a sheltered position so that a gust of wind will not scatter the flaming dirt over the car and cause a conflagration. As soon as the operation is finished, the flames should be smothered with dirt and the "forge" broken up and scattered over the road.

Wrench Handle Can be Used as Soldering Iron—An excellent substitute for a soldering iron is the steel handle of a wrench or the blade of a screw-driver, the handle or blade being cleaned and tinned in the same manner as the regular iron. By keeping a wrench with the handle ready tinned, the soldering iron can be dispensed with, and its place in the tool-roll given over to another tool or to tire tape, twine, etc. As regards solder, ordinary electric fuse wire will serve the purpose equally well, and can often be obtained from electricians and hardware dealers, who carry only the large bar solder. Solder in any form is, of course, equally efficient, but the strip form is to be preferred.

CONCERNING THE OFFSETTING GAS ENGINE CYLINDERS

By COKER F. CLARKSON, A. L. A. M.

THE invention and development of the gasoline automobile has brought about the evolution of an engine which differs from the gas engine of the stationary type in as marked degree as the latter differs from the steam engine. Though a dozen years ago the stationary gas engine designer would have ridiculed the idea of successfully producing a gas engine weighing less than ten pounds per horsepower developed, this, and more, has now been accomplished. It is futile to expect that automobile engineers will ever be thoroughly in accord on a subject involving so many opportunities for detail differences as automobile motor design; though, of course, years of experience have resulted in a type of construction followed so closely in such a larger number of instances as to warrant being termed standard practice in this respect. Whether taken singly or collectively the cars produced by the members of the Association of Licensed Automobile Manufacturers reveal more accord than difference in design.

The ordinary way of placing automobile engine cylinders with relation to the crankshaft (whence, of course, the power is taken off) is medially over the axis of the crankshaft. But for years, several years in some instances, some cars have had cylinders offset with relation to their crankshaft, that is, in a position wherein the center line of the cylinders is not opposite but to one side of the axis of the crankshaft. This difference in practice raises a very interesting and much discussed subject. It has been said that inasmuch as a gasoline motor crankshaft revolves in only one direction, it is mere common sense to place the cylinders in such a position that the pistons will transmit the power impulses to the crankshaft most effectively, that is, offset so that the maximum force of explosion is delivered on the piston when the crank is past the top vertical center line and therefore in the best position to receive it, and the pressure on the cylinder wall during fifteen to thirty degrees of the firing stroke is, owing to the reduction of side-thrust, diminished. While this statement may be true, it is apt to be misleading, and in any event is not the only consideration. There are very positive advocates both for and against offset cylinders. Among the advantages claimed for offsetting are: Shorter connecting-rods, reduced wear, lighter construction, reduced friction between the pistons and cylinders on the power stroke, more direct turning effect on the crankshaft, less likelihood of a knocking motor, less shock on the engine bearings, less overall motor height necessary, greater motor flexibility and appreciable increase in power.

On the other hand it is said by those who prefer the construction wherein the cylinders are placed medially opposite the crankshaft that the claimed advantages of reduced side-thrust on the power stroke and more direct turning effect on the crankshaft have not much more than a theoretical value; that in T-head motors, with their two camshafts, offset cylinders involve complication desirable to avoid; and per contra statement above, that knocks are more common and wear is greater than in the usual type of engine. Further it is said that the offset becomes less advantageous at high engine speeds. Perhaps the most commonly advanced argument against offset cylinders is that the engine is thrown out of balance when they are used.

The controversy comes down to these two general positions, namely, on the one hand that in properly proportioned design it is unnecessary to offset cylinders in order to take care of the alleged counterbalancing advantage of doing so, less side-thrust on cylinder walls on the power stroke, etc.; and on the other hand that if an engine with offset cylinders is made as it should be, certain distinct advantages which have been suggested above are gained and clearly counterbalance any consequent disadvantages there may be.

A RATING FORMULA WHICH CONSIDERS STROKE

IN conjunction with the constant stirring up of the subject of empirical formulas for rating automobile and similar engines, one advanced by the well-known English manufacturers, Rolls-Royce, Limited, seems to possess some merit. This includes the use of the stroke, a point, the omission of which in the now standard formula has puzzled many.

The English makers propose that engines be rated at the power deduced by the use of the formula:

$$\text{Horsepower} = .25\ (d - 1\text{-}2)^2 N \sqrt{s}$$

in which d denoted the diameter of the cylinder in inches, s, the length of the stroke, and N, the number of cylinders employed. As most of the engines in use in this country are of the four-cylinder variety, the figure for N is nearly always four. Then multiplying by .25, which is equivalent to dividing by four, and then later multiplying by four again, is needless work. So for four-cylinder purposes, the formula reduces to:

$$\text{Horsepower} = (d - 1\text{-}2)^2 \sqrt{s}$$

Using this, the power rating from 4 by 4, 4 by 4 1-2 and 4 by 5 engines, all of which would otherwise be rated at 25.6, would be respectively 24.5, 27.2 and 30.

A Stop at Mt. Washington Hotel, Bretton Woods, N. H.

IMPROVING WHITE MOUNTAIN ROADS

BRETTON WOODS, N. H., June 14—Good news for automobile tourists is coming through the Crawford Notch and over other roads leading to this place, for gangs of men are now at work repairing them for the season. John Anderson, of the Mount Washington and Mount Pleasant hotels, says:

"The State of New Hampshire has taken a great interest in the highways leading to Bretton Woods, especially through Crawford Notch, where an enormous rock fill is being made to ease the grade at the foot of the last steep climb approaching the 'Gateway.' The walls at the top of the pass, at the crown of the hill, are being blasted out to widen the gap, and the rock thus obtained is being used in making the fill. The road will be nearly 20 feet wide, double its former size, and yet so carefully is the blasting being done that not one out of a dozen of those coming up will notice any change in the rugged grandeur of the pass. The sheer wall at the very gate of the Notch will not be touched. 'Tug-of-war Hill,' which formerly was a terror to autoists, was made easy by order of the State last year, and the work this year will remove the last serious difficulty in the passage of the Notch.

"From the Wiley House to Bemis the road is being widened and the curves straightened, under the supervision of H. S. Mudgett, of the Intervale House, and considerable progress has been made. It is planned to make the road 15 feet wide at the narrowest places and 18 feet wherever it is possible. So much stone has been moved back in widening that the appearance now is of a stone wall on each side of the highway. All of the roads in this section wintered extremely well and are in good condition now. Three automobile parties have been at the Bretton Arms already, and we expect the Albany Automobile Club to be here on June 23 on its annual tour. In riding through the Notch a few days ago we saw a deer standing in the road only a short distance ahead of us."

FROM A TOWN IN NOVA SCOTIA

ANNAPOLIS, N. S., CANADA, June 7—Automobile drivers in this town have agreed to keep their cars off the public highways on Saturdays and Sundays between the hours of 9 A. M. and 5 P. M. This peculiar condition has been brought about through proposed legal action on the part of the municipal council to prohibit the use of automobiles in Yarmouth County on these days between 8 A. M. and midnight, thus giving the autos the right to be used only during the early hours of the morning. Something sidetracked the measure, and to prevent the necessity of an extra session to take up the outstanding measures, the autoists themselves made the agreement. Notices will be posted in the hotels of the county.

AMERICANS TOURING EUROPE IN PLENTY

PARIS, June 3—The rush of American automobile tourists to Europe this year commenced much earlier than usual, and to judge from present indications will be a record one. The tendency of the last two years for automobilists to bring over their own cars is more pronounced than ever, and there will doubtless be few leading American firms that will not be represented by touring parties this summer. The Packard still holds the lead as the American car most generally employed for foreign touring. H. D. Wilson, the European representative of the company, declares that at the end of May he had been in touch with 57 different parties touring Europe in Packard cars, this being a remarkable number when it is considered that the touring season is not supposed to begin until the middle of June. The number, of course, does not include all Packard cars running through Europe, for many of the tourists having no need of either spares or touring information do not report at headquarters. Among those having reported during the past month are two directors of the company—Russell Alger, who has just purchased a Wright aeroplane, and Phillip McMillan; Truman H. Newbury, ex-secretary to the navy; Charles M. Schwab, Thomas Nelson Page, the author; A. S. Carhart, of Tuxedo, and Edgerton Winthrop.

The Pierce agent, N. F. Goodsill, also reports an increased number of visitors to the company's touring bureau in the Avenue de la Grande Armée, Paris. A third American firm to establish an American depot for spare parts and touring information is the Peerless Motor Car Company, whose Paris depot is located at the new American garage in the Rue du Mont Thabor, in the center of the hotel district, in charge of Manager Bousquet. Among the other firms not possessing European touring offices, but whose cars have been reported in the city garages during the past few weeks are White, Locomobile, Thomas and Rambler.

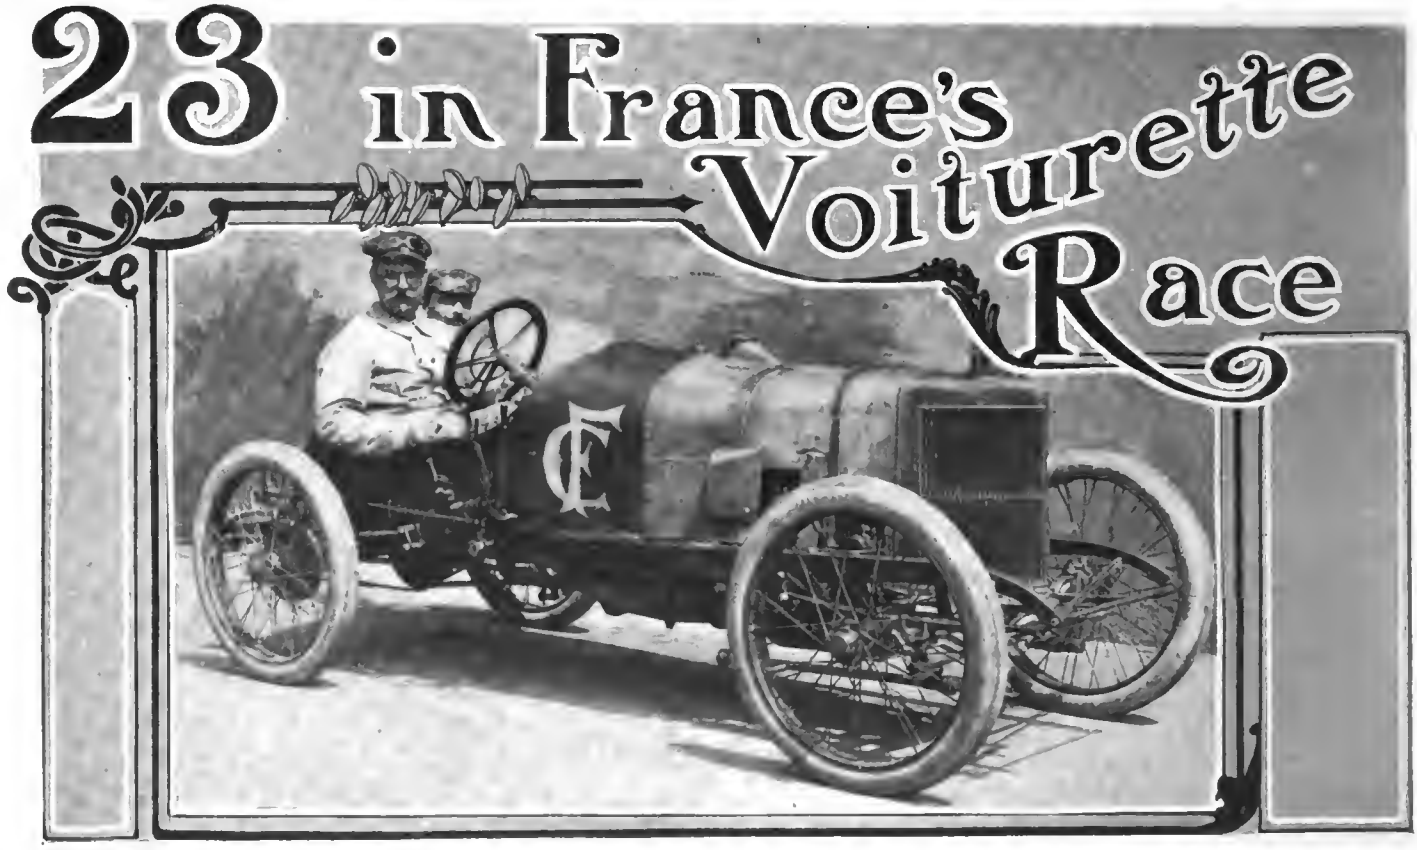
ST. JOHN AUTOISTS ASK CARE IN TOURING

ST. JOHN, N. B., CAN., June 7—Legislation against automobiles has been threatened for some time in New Brunswick, and the New Brunswick Automobile Association has taken steps to prevent the necessity and to quiet any demand for it. The club has issued a circular to be distributed at all ports of entry, so that visiting autoists will have their attention called to the law regarding speed, and especially to the use of caution in passing teams. Trouble has occurred too frequently in the latter case, and is the principal cause for complaint. Furthermore, some advertising will be done in the press, asking that all offenders be reported to the association, and this body will make prompt inquries, and if necessary prosecute. It is considered that the delays in stopping for teams will not greatly affect tourists, for there are many roads in this province where a car can be driven for 15 or 20 minutes at a time without meeting horses.

At the recent annual meeting of the automobile association it was decided to offer prizes to the three road commissioners effecting the greatest improvements in their respective sections.

The Commodious Garage of the Mt. Washington Hotel

23 in France's Voiturette Race



Manufacturer Crespelle, a Newcomer in the Racing Game, at Wheel of One of His Voiturette Racers

PARIS, June 10—Twenty-three small cars will start in the voiturette race at Boulogne-sur-Mer on Sunday June 20, the only pure speed contest to be held in France this year. For a long time it looked as if the solitary race was doomed to failure, for the entries stood at six for several weeks, and it was only during the three days preceding the final closing that the number was run up to 23. France, England, Belgium and Spain are the countries represented, the first-named having the majority of entries, the others being content with one team each.

Unlike the previous voiturette races in France, one-lunger racers will not be in the majority this year. Lion-Peugeot, whose recent successes at Barcelona and in Sicily have made them the favorites for the Boulogne race, will present two single-cylinder cars and one twin-cylinder. The one-lungers are special productions with a bore of 3.9 inches and a stroke of 10 inches; as on all the special racing cars, they will have enormous valve area, but instead of a single inlet and exhaust, which is apt to give trouble by reason of warping, there will be three of each, operated by an original type of rocker arm. The two-cylinder car has a bore of 3.1 inches and a stroke of 7.8 inches. Although this car has won the two previous races of the year, it is slightly inferior in speed to the one-lungers from the same factory, its victory in Sicily having been due to its companion running out of gasoline, and at Barcelona to the breaking of the road wheels of both its team mates. All three cars develop about 35 horsepower, and can easily maintain a speed of 60 miles an hour on the straight away.

Thomas, the ex-motorcyclist, will handle a Le Gui voiturette with a single-cylinder De Dion motor of 3.9 by 10 inches bore and stroke. Maurice Fournier, younger brother of the better known Henry Fournier, will take the wheel of a Werner fitted with an engine similar to that of the Le Gui. Three Crespelle cars, newcomers to the racing game, will have practically the same power plant. The French firm Alcyon will this year put its faith in four-cylinder cars, having the minimum bore of 2 1-2 inches and the maximum stroke of 5 1-2 inches. The chief driver is Barriaux, an old voiturette hand, with a couple of team mates yet to be chosen. Renault-Schneider, a St. Etienne firm, is an entirely newcomer to the automobile world, and intends to make its debut on the race track with commercial models of 2.7 and 4 inches bore, which have little chance of winning first prize.

England is represented for the first time in a French voiturette race with three Calthorpe four-cylinder cars of 2 1-2 inches bore by 5 1-10 inches stroke. The engine has its cylinders in a single casting, Hele-Shaw clutch, sliding gear transmission, and final drive by cardan shaft. One of the interesting features is the use of Rudge Whitworth dismountable wheels, very largely employed on the other side of the Channel, but not previously demonstrated on the Continent. Spain sends a full team of four-cylinder cars with engine dimensions 2 1-2 by 5 1-2 bore and stroke. The drivers are Zuccarelli, for a long time Lancia's mechanic; Derny, an ex-Clement champion, who figured in Paris-Madrid and Paris-Vienna, and Pilliverdie, a newcomer to the game. Belgium has forwarded the engagement of three cars known as the Rif. The firm is recently established, and nothing has yet been made known regarding the car.

The race will be run on a very varied course having grades up to 13 per cent., and measuring 23 3-10 miles round. Ten rounds will be covered without controls.

BRITISH GRAND PRIX VOITURETTES

COVENTRY, ENGLAND, June 8—The three Calthorpe cars which are to be Great Britain's sole representatives in the Grand Prix des Voiturettes have been completed, and road tests have shown that these litttle vehicles are well able to make a good showing. The engine has four cylinders cast en bloc, the bore being 66 millimeters, with a stroke of 130 millimeters, and no less than 22 B.H.P. was recorded during the bench tests. The Hele-Shaw disc clutch, three-speed gearbox and aluminum rear axle casing follow the lines of the standard Calthrope voiturette. Rudge-Whitworth detachable wire wheels are fitted and these have proved of special value in enabling the effective gearing of the car to be modified to best advantage by fitting a smaller size. The body is of sheet aluminum and the total weight has been kept below 800 pounds. Until but a few days ago the race

seemed likely to be confined to the Lion-Pugeot and these Calthorpe cars, but it has just been announced that definite entries have been made for teams of Alcyon and Hispano-Suiza cars, both having four-cylinder engines. The contest between the English and Spanish entries will be followed with much interest, as the power plants are practically indentical.

AMATEUR RACE AT BROOKLANDS.

LONDON, June 1—The racing of Saturday and yesterday proved to be most interesting and the big fields and close finishes more than compensated for the absence of the high-speed record attempts that had been promised. The 15-horsepower Lancia commenced its successes with the first race, the Regent Cup for cars of under 20-horsepower, R. A. C. rating. For the whole of the nine and one-half miles the Lancia and its rival, the Vauxhall, kept side by side, and the latter was finally beaten by but a couple of yards. The speed average was 62 miles an hour. The Vauxhall regained top place in the next event, the Whitsun Handicap for members of the Brooklands Club. The Lancia was not running, and the Vauxhall had an easy win, an exciting tussle for second taking place between a 20-horsepower Mercedes and a 12-horsepower Sizaire, to the benefit of the latter. Several private matches were followed by a race for Jackson 6-horsepower cars, nine of which faced the starter. The winner averaged 39 miles an hour for the three miles, and the others all finished in a bunch. The invariable closeness of the finishes makes these standard car races very popular.

The May Senior Handicap brought out a curious medley of cars, ranging from a 16-horsepower Argyll to a Mercedes of 120 horsepower and an Itala of equal power—both Grand Prix cars. The first two laps provided ample excitement, albeit the Itala and the 90-horsepower Napier were both out of the race. When the leaders were entering the finishing straight the big Mercedes kept on round the outer course and so lost the race. The Lancia got in first at a speed of 68 miles an hour, while for second place the Iris barely defeated the Vauxhall. The first of the motorcycle races had 27 starters, and the winner, Cook, on a 7-horsepower N. L. G., averaged 68 miles an hour for the six miles. In the other event for these machines a 5-horsepower Indian gave a good race for first place, but was just beaten by a length. An obstacle race for cars, ending with a run up the test hill, completed the day's programme.

On Monday the Vauxhall led off with a win in the May Junior Handicap, the Lancia just 10 yards behind. Next came the Four-Inch race, when the only racing De Dion ever turned out from the Puteaux factory ran in first at 71 miles per hour, the Hutton, which won the Isle of Man race, being second, followed by a Humber and a Darracq. But the event of the day was the Whitsun Senior Handicap, for which 16 cars turned out. Excitement was aroused at the start and culminated at the finish when the Vauxhall won, not a length ahead of a "Knight" Daimler and a 40-horsepower Napier. The 120 Mercedes did well, averaging nearly 105 miles an hour for the 11 miles, but its handicap was too heavy to be made up.

A novelty was provided in the team race, open to pairs of cars with a total rating of under 60 horsepower. One car of each team ran a circuit, and as soon as the driver had handed a voucher to his team mate, the latter covered a circuit to the finishing post. The winners proved to be a 20-horsepower Nagant and a 40-horsepower Napier.

Finally came the Winners' Handicap, in which all the winners of both days competed, motorcycles and cars together. The smaller machines greatly added to the excitement and a 5-horsepower Indian was just beaten for first place by a 12-horsepower Sizaire car. The next meet will be held on Wednesday, June 30.

AUTOMATIC SPEED ALARMS COMPULSORY

LONDON, June 8—The advent of the legions of motor buses and cabs—there are now over 3,000 of the latter vehicles in London—has greatly increased the dangers of traffic on account of the excessive speeds continually maintained by the drivers. To check this evil the Commissioner of the Metropolitan Police has taken the decisive step of requiring that all public-service motor vehicles be fitted with an automatic device which will give audible warning whenever the speed limit is exceeded. The exact form of the device is left to the judgment of the operating companies, but it must be sealed up out of control of the driver and the warning must be loud and continuous so long as the statutory speed is being exceeded. Unless the combined opposition of the companies causes the withdrawal of this regulation it will come into force on July 1 next.

ENGLAND'S MOTORCYCLE RELIABILITY RUN

LONDON, June 3—The reliability of the modern automobile is fast becoming proverbial, but occasionally the fact is brought home in a special manner. For the sixth annual 24 hours run from London to Edinburgh, which was held last Friday by the Motor Cycling Club, 112 motorcycles and 28 cars were entered. Of the 124 starters no fewer than 113 completed the journey of 400 miles within the 24 hours, while 106 finished in the minimum time of 22 1-2 hours. Thirty-two of the more venturesome, including the only lady competitor, Miss Muriel Hind, started on the return journey after a day's rest. All but one of these finished inside schedule time, so that the task of choosing the winner presents some difficulty to the club officials.

When New York's Orphans Arrived via Automobile at Dreamland, Coney Island—The Fairyland of Young America

NEW YORK'S orphans, nearly 2,400 of them, were on Friday treated to one of those outings which are year-marks in their lives, a real automobile parade, a long ride, and the freedom of the wonders of Dreamland, Coney Island. This fifth annual celebration of the orphans' day, now under the management of a corporation, was the most successful of the quintette of excursions given to the inmates of the charitable institutions of the city, and there were about 150 automobiles in which to entertain them. Rain had caused a postponement of the event from last Wednesday to Friday, but there was no diminution in the interest, either on the part of the small folk or of the donors of the cars, and long before 9 o'clock in the morning the autos were reporting to the headquarters of the committee for orders. The various institutions were then visited and the loads of happy children brought to the streets near Columbus Circle, where they were marshaled into divisions, and the parade began. After a run through the city streets, the cavalcade wound around the approach to, and then over the new Queensboro Bridge, and on to Coney Island.

Grand Marshal Owen Leading Procession Down Broadway

The Omnibus Division Was Extremely Popular with Boys

Dreamland was thrown open to the two-score hundred orphans and full advantage was taken of the hospitality. Those who were getting their first trip were fully informed by those who have been on hand in previous years, of the delights before them, and they who had taken the trouble to get up the affair were fuliy repaid by the evident pleasure of their guests. The big dining hall served 2,400 meals, and thereby once more experienced the capacity of the small boy and girl. Three items illustrate that: there were 4,000 oranges supplied, 20 cans of milk were not sufficient, and 3,700 large rolls—really small loaves of bread—were distributed. A substantial meal was served and great amusement was afforded the watchers at the antics of the youngsters. One table was not supplied with tumblers, but there was a decanter of water, and the boys decided that glasses were really not necessary; they stuffed their pockets whenever a chance permitted—that is when another youth was not watching; they vied with each other to see how many bricks of ice cream they could procure, and some little codgers were so anxious to satisfy a healthy appetite that they tried to eat with knifes and forks at the same time, thus using both hands.

After lunch the shows were visited, the animals, the shoot-the shoots, the scenic railway, the Philippinos, and all the other attractions held their attention, and 4 o'clock came all too soon for them. At that hour the autos were again lined up, the confusion settled, and the parade proceeded again to the big city. The police officials were especially efficient, keeping the roads and crossings clear during the passage of the autos, and in many cases facilitating their movement.

The corporation in charge of the orphans' day celebration, known as the Orphans' Day Committee, has as officers: President, Col. K. C. Pardee; vice-president and general manager, W. J. Morgan; treasurer, Richard Newton; secretary, Alex. Schwalbach; grand marshal, Percy Owen. The auxiliary committee, which raised a large amount of money and secured many private cars, is composed of: Mrs. Norwood T. Smith, chairman; Mrs. Thomas Nash, Miss Nash, Mrs. W. A. Alston, Miss A. McIntyre, Mrs. H. Badgley, Miss Howell, Miss Knox and Mrs. E. H. Barrows.

The following cars were represented: Packard, 4: Pierce-Arrow, 4; Stoddard-Dayton, 2; Stearns; Knox, 2; White, 7: De Dion, 2; Plymouth trucks, 3; Frayer-Miller truck; Kissel Kar, 3; Thomas; Manhattan Sight-Seeing cars, 3; Yellow Taxi-

cabs, Wycoff, Church & Partridge, 6; New York Taxicab opera buses, 6; Pullman, 2; Brush; Palmer & Singer; Studebaker, 2; Mercedes, 3; Royal Tourist; Autocar; Berliet; Pope-Hartford; Mora; Cadillac; Maxwell, 7; Rambler, 3; Winton; Alco, 3; Ranier, 3; Matheson; Hotchkiss; Oldsmobile, 6; Selden; Regal; Overland; Lozier; Reo, 2; Atlas; Renault, Stevens-Duryea; National, 2; Franklin, 4; Bianchi; Locomobile; Mitchell; Fifth Avenue Coach Company, 6 busses; Twentieth Century Touring Company, 6 buses; Taxi-Service Company, 5 taxicabs, 3 touring cars; there were other cars which reported at the last minute and were not listed.

QUAKERS TAKE ORPHANS TO WILLOW GROVE

PHILADELPHIA, June 14—Threatening weather came within an ace of spoiling the annual orphans' day run of the Quaker City Motor Club, which had been postponed on account of rain from Wednesday last to the following Friday. At the starting hour, 9 o'clock, there was every indication of rain and another postponement; but Chairman E. H. Lewis decided to take a chance, and won out, as before noon old Sol was doing business in his best midsummer fashion. The lowering clouds, however, reduced the number of cars from the 100 promised to 92. These accommodated upward of 600 little ones, representing 21 institutions, who were given the time of their lives.

Upon arrival at Willow Grove, the children were met by a reception committee of club members and ladies connected with the Quaker City Ladies' Motor Club, who distributed tickets admitting the "kids" to the delights of the park—mountain trip, roller coaster, airship flight, trip to Venice, moving pictures, etc. At one o'clock the little guests were summoned to grove No. 1, where they made partially successful efforts to put away the lunch provided for an even thousand and supplemented by a thousand boxes of candy donated by Mrs. E. D. Kruse.

At three o'clock, Chairman Lewis and his committee began to round up the little ones, who were engaged in "repeating" on the attractions, with the overplus of tickets which had been distributed. Despite the lure of the Midway, the "kiddies" were corraled by four o'clock and all reached their respective institutions an hour later without a single mishap.

The committee had endeavored to induce the turnpike company owning the road to Willow Grove, to suspend toll collections on all cars carrying orphans, but upon their refusal the *Evening Times* stepped forward with an offer to foot the toll bill, which was gratefully accepted. All told, the day's outing was a happy one, long to be remembered by entertainers and guests.

Fleet of Yellow Taxicabs Laden with Youngsters

President Webb and Dr. Richardson, L. I. Club Committee

ORPHANS INTEREST WEALTHY BROOKLYNITES

When the Long Island Automobile Club officials in charge of the Orphans' Day celebration interested the wealthy folks of Brooklyn, they did a wise store of business. The result was that instead of a lack of cars and money to further the plans, President Frank G. Webb and Chairman of Outings Dr. William P. Richardson, were put to more trouble in getting the "kids" to forsake Coney Island with its new and wonderful delights, when it came time to go home. The outing was voted a great success by all of the children, so the committee should be well satisfied with the results of their labors. The picture above shows the two officials before the car in which they led the parade.

BLIND CHILDREN HAVE OUTING IN BOSTON

BOSTON, June 12—The annual outing for blind children given by the Boston Automobile Dealers' Association took place Wednesday and 125 little ones deprived of their sight and pupils at the Perkins Institution for the Blind, in South Boston, and of the Kindergarten for the Blind, in Jamaica Plain, were taken to the Lakeside Home on the shore of Lake Massapoag in Sharon in cars supplied by the local dealers. The Lakeside Home is a charitable institution for children, of which Rev. M. R. Deming is superintendent, and there the children were entertained during the day.

The cars assembled in Copley Square between 9:30 and 9 o'clock, and after picking up the blind children and their teachers and leaders, were driven the ten miles or more through the parkways and boulevards and over excellent country roads to Sharon. After a day spent in out-of-door amusements, the children were returned to their abiding places. Those who supplied cars were: W. H. Jenkins Company, Mitchell; Buick Motor Company, Dodge Motor Vehicle Company, Pope-Hartford Franklin Automobile Company, Winton Motor Carriage Company, J. M. Linscott Company, National; J. W. Bowman Company, Stevens-Duryea; Premier depot, L. B. Butler, Whitten-Gilmore Company, Thomas; Ford Motor Company, F. E. Wing, Marmon; Park Square Auto Station, Stoddard-Dayton; J. H. MacAlman, Stearns; Thomas B. Jeffery & Company, Rambler; Henry H. Pierce, Alvan T. Fuller, Packard truck; the White Company, J. W. Maguire, Pierce; V. A. Charles, Inter-State; K. M. Blake, Locomobile; George H. Lowe, Pennsylvania; Leonard A. Day, W. J. Cooper, William F. Mayo, Frank C. Snyder and Kenneth A. Skinner.

KANSAS CITY'S ORPHANS' DAY PARADE

KANSAS CITY, Mo., June 14—The Automobile Club of Kansas City held its third annual Orphans' Day on June 9. At three o'clock in the afternoon 60 cars laden with 300 orphan children started from Armour boulevard and Broadway for a 30-mile ride out to Swope Park. Following a new departure this year the committee decided to form the parade entirely of cars owned by club members, and was very successful in obtaining the use of enough cars to comfortably seat every one. At the start each one was given a souvenir flag and all of the cars carried pennants. Waving their flags and constantly shouting at every one passing by, the children certainly made the most of their holiday.

This custom of giving the orphan children an outing has become a fixed annual affair here, and will undoubtedly remain so because of its popularity. In addition to its charitable nature, which is in itself sufficient reason, the club derives a certain benefit from it in good will of the community and increase in membership applications.

RAIN INTERFERED AT BALTIMORE

BALTIMORE, June 14—The continual rain of the past week made it necessary for the members of the Automobile Club of Maryland to postpone the orphans' day outing from last Wednesday. In consequence of this enforced action on the part of the club members more than 800 little ones who had looked forward to a pleasant trip through the prettiest sections of the city and suburbs were disappointed. The owners of cars in this city entered into the spirit of the occasion so that nearly two hundred cars were offered for the entertainment of the children at Electric Park. These are still at the disposal of the club when a clear day comes along for the outing.

COLUMBUS ORPHANS WILL BE HAPPY

COLUMBUS, O., June 14—Arrangements have not been completed for the annual orphan's day to be given by the Columbus Ohio Automobile Club, June 19. It will require at least 200 cars to carry the children. Requests have also been made for "goodies" such as candies, peanuts and ice cream.

CONDITIONS IN FRENCH AUTO INDUSTRY

Overproduction, much price cutting, high taxation, liability of arrest, and reduced taxicab charges, are greatly harming the automobile business in France, according to A. E. Schwartz of Paris, foreign representative of the American Motor Car Manufacturers' Association, who is now in this country on a business trip. Mr. Schwartz was impressed with the immensity of the American industry when he arrived a few days ago, and in comparing it with the conditions in France, said:

"There is an enormous difference, for every one here seems busy, whereas in Paris the dealers have to sell sporting goods, bicycles, and other things to pay expenses. There has been a large overproduction of automobiles, and if a European manufacturer were told of the status of the American industry he would be incredulous, and call it a 'bluff.' In France the private purchaser can get the same discount from a maker as the dealer, and therefore the buyers do not deal with agents but go direct to the factory. Another difficulty is with the taxation which requires the payment of five francs (one dollar) for each seat, and five francs for each horsepower, so that if one buys a 30-horsepower car with four seats, the tax is 170 francs; and this must be paid to the State and then to the city, making the charge 340 francs ($68).

"Coupled with this is the practice of arresting automobilists on the least provocation, such as for smoking when the exhaust is no thicker than that emitted by a pipe or cigar smoker. Then the police try their best to fine for something else at the same time, the result generally being a charge of about 50 francs. These things have hurt the industry. Another matter which has contributed is the reduction of taxicab rates, so that now a cab can be rented for 50 cents an hour, for four people, and many have sold their machines. which they used only in the city, and thereby rid themselves of the bother caused by the police, garages, chauffeurs, and the expense, preferring to use the taxicabs.

"A very interesting fact is the great number of people that have taken up the aeroplane and aerial navigation in general. There is many a man who is and was famously known at the steering wheel of an automobile, who has his little idea up his sleeve for a new device for aeroplanes, and I know of one big accessory store that claims to do more business in supplies for aeroplanes than for automobiles, in the last few years."

N. H. VAN SICKLEN, SR., JOINS BLUE BOOK

The rapidly increasing demand for touring information in all sections of the country has necessitated a larger organization to carry on the work of "The Official Automobile Blue Book," and a new corporation, with largely increased facilities, has been formed under the incorporated name of The Automobile Blue Book Publishing Company.

N. H. Van Sicklen, Sr., former owner of *Motor Age*, and recently Chicago branch manager for the Knox Automobile Company, and one of the most widely known men in the automobile industry, is president of the new corporation, and he, with the former owners of the "Blue Book," will constitute the board of directors. Mr. Van Sicklen will immediately inaugurate a strong campaign for the extension of the "Blue Book's" scope and influence, so as to practically cover the entire United States, Canada, and Mexico. Headquarters will be in New York and Chicago.

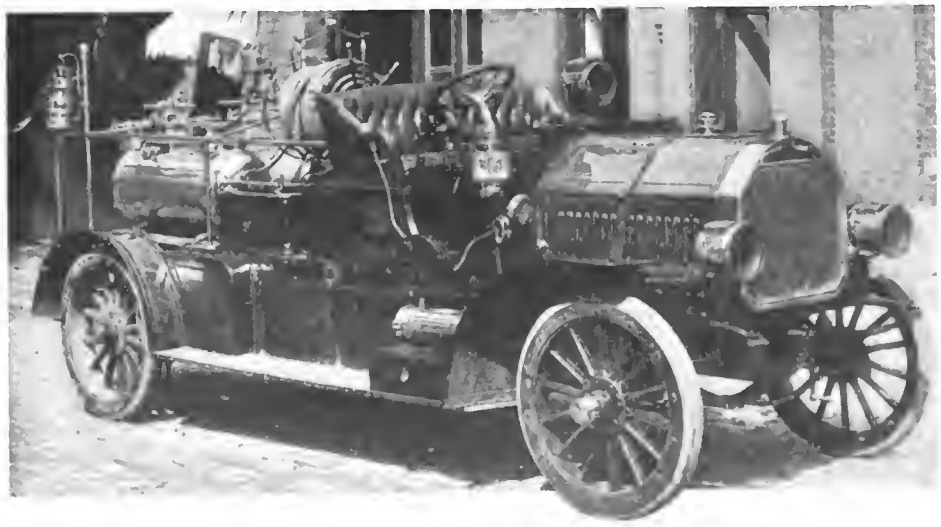
"The Official Automobile Blue Book" is now recognized as the standard route book for this country, and under Mr. Van Sicklen's management the new corporation will extend its work to cover every requirement of the automobile tourist.

EX-CHAIRMAN J. D. THOMPSON GOES ABROAD

Jefferson DeMont Thompson, ex-chairman of the A. A. A. racing board and Vanderbilt Cup commission, recently sailed for the other side for a summer vacation in Europe, where he will tour in France, Germany, and Austria.

MODERN FIRE DEPARTMENTS NOW USE AUTOMOBILES

EVEN if the Senate of this great country does not approve of the automobile, it is a fact that its use is not only increasing daily with leaps and bounds, but is fast extending into other fields of endeavor. The strange part of this is that it always makes good, no matter what the use may be.



Auto-Car Chemical Truck for Fire Department, Ocean Grove, N. J.

Thus most of the progressive fire companies have tried the self-propelled car, the trial resulting in its adoption. The latest to fall into line is the H. E. Stokes Fire Company No. 3, of Ocean Grove, N. J. This company has just purchased and put into use a truck of the high-speed type, as manufactured by the Auto-Car Manufacturing Company, of Buffalo, N. Y. The Auto-Car company has been in the commercial car business for many years and its product shows this in the little details. This particular car is powered with a 40-50-horsepower engine, so geared as to allow a speed of 50 miles per hour on the high gear. It is equipped with two 35-gallon tanks, 150 feet of hose and has ample room for 12 to 16 men. The truck was adopted by the hose company after a very severe test, which took the form of a trial run over country roads with a heavy load. The distance was 45 miles, which was covered with a load of 14 firemen, in the excellent time of 53 minutes, or at the rate of 51 miles an hour, thus proving the maker's claim of a speed of 50 miles in the best possible manner. The main object in making the run was to show the great advantage of motor chemical trucks in case help is called for by near-by towns. This truck is one of the first products of the Auto-Car company's new factory, located on Elmwood avenue, Buffalo, which is a very modern commercial car factory, with improved facilities. The annual output of the company is now about one thousand cars per year, chief among which are numerous machines of the type illustrated and described, the demand for these fire wagons having increased to a wonderful extent in the past few years.

RAMBLER CHASSIS FOR WESTERN FIRE DEPARTMENTS

NOT to be outdone by any of their Eastern rivals, the city authorities of Pomona, Cal., have recently put into commission a chemical fire engine, and so great has been its success in the short time it has seen practical use, that the city of San Diego, not very far from Pomona, is about to construct and put into service a similar outfit. The Pomona car is built upon a Model 45 Rambler chassis, of 45 horsepower. The wheelbase is that of the standard touring car of this model, namely, 124 inches, as the Thomas B. Jeffery Company has never attempted to build commercial cars, although the chassis are finding much favor for this strenuous work. The chemical apparatus, consisting of three large tanks, numerous small tanks for hand use, hose and hose-carrying mechanism were fitted to the chassis in California, upon its arrival there. One of the tanks is located alongside of the driver, in the unoccupied front space, while the others are placed in the back. The hose reel, with a capacity of 150 feet of hose, is placed across the car right back of the driver's seat. The running boards and the remaining space at the back allow standing room for about ten or a dozen firemen. On the trial trip of the completed car, a fire was reached within two minutes of the sounding of the alarm, thus showing plainly the large improvement in the speed of the service over the previous horse-drawn wagons.

Rambler Chassis with Home-built Body in Service of Pomona, Cal., Fire Department

DUBLIN, June 2—When the contesting cars in the Irish Reliability Trials reached Dublin, at the finish of the week's work, for it was real work, there were but twenty of the fifty-two starters left with perfect scores. Among these, distributed over eight classes, with but three exceptions the winning cars in the hill climbing contests were noticeably absent. Of the three classes one of them had but a single car, so there was no competition. There remained, then, but two cars, which won all three of the hill climbing contests and scored perfect for the six days of running over the miserable Irish roads, thus bringing out the lesson of the tour, namely, that hill climbers are seldom reliability winners, and vice versa, reliability winners do not usually take the prize for hill climbing.

These two exceptions were the 12-horsepower Riley in class C, for cars from £150 to £250 ($750-$1,250), and the 16-horsepower Humber in class D for cars costing under £350 ($1,750). Notable among this list of absentees from the perfect score survivors were the 25 Talbot and the 24 Vauxhall in class F. The former had clutch trouble from the start, but made the fastest time up Grecnan's Hill and Farmer's Bridge Hill, while the latter outdid the other fifty cars on Magilligan Strand. Of the remaining seventeen perfect score cars but two did anything worthy of mention in the speed tests and hill climbing.

Beginning on the first day and continuing throughout the trial, there were cars in trouble at all times. The miserable Irish roads tested the frames and running gear to the limit, and those contestants who had not made adequate provision for the worst test that the car would ever experience, were soon to be found strung along the roadside, working on some sprung or broken parts. The springs, propeller shaft, fuel systems, and lubrication troubles caused the greatest number of victims.

Thus, the 15-horsepower Mass had spring trouble continuously, proving that the springing of this car was not adapted to this kind of country. On the first day a broken spring held the car and crew for 19 minutes, which penalty was increased by 55 minutes more on Saturday, when another spring failed. Later the crew of this car received and placed on it another full set of springs.

This and the large amount of shaft trouble showed more than words the roads. On the third day out, just beyond Westport, the 15-18 Bedford broke its propeller shaft and withdrew from the contest. Next day, within four miles of each other, the two Chenard-Walckers broke their propeller shafts crossing culverts, with which this day's trip was replete. This was very unfortunate, for at the time of the accident both cars were running very regularly and both had perfect scores.

Taking the tour as it went, from day to day, there were an average of five cars per day put out of the non-stop division, up to the last day, when the only cars to have trouble were the 12-horsepower Star and the 14-16 Motobloc. The former had a leaking gasoline cock, which allowed the fuel to waste away, necessitating a renewal from an unsealed can, this day's run being made a fuel consumption test with measured quantities of gasoline. The Motobloc had the same kind of a loss, breaking its gasoline pipe, which accident cost 19 points penalty.

Arriving at Dublin each car's tank was emptied and the amount of spirit remaining carefully measured, this amount being entered upon the official records. As this gasoline consumption has not yet been announced, and will not be for some time, it is impossible to state finally which car or cars have won the contest, if there be any winner, or which stands highest in the classes.

The following list, however, subject to official verification, gives the list of perfect scores made. It now appears as if the Dunlop Cup for the best performance of a team of cars will have been gained by the Humber cars, with the American-made Cadillacs or the Stars in second place.

Class A (price not exceeding £150 or $750), 15-horsepower Bedford.

Class B (price £150 to £200 or $750 to $1,000), 8-horsepower Riley and 10-horsepower Riley.

Class C (price £150 to £250 or $750 to $1,250), 10-horsepower Humber, 12-horsepower Riley and 12-horsepower Star.

Class C 1 (£200 to £260, two-seated bodies), 12-horsepower Marlborough.

Class D (under £350), 15-horsepower Marlborough, 16-horsepower Humber, 30-horsepower Cadillac, 30-horsepower Cadillac, 15-horsepower Rover, 15-horsepower Straker-Squire and 16-horsepower Humber.

Class E (£350 to £450), 15-horsepower Deasy, 20-horsepower Vauxhall and 20-horsepower Vauxhall.

Class F (£450 to £550), 18-horsepower British Gladiator, 20-horsepower Sunbeam.

Class G (£550 to £700), 40-horsepower Gladiator.

In many senses the Trial was the most severe held so far, and as will be seen from what has been said, although the casualties have not been done in detail, it has been somewhat remarkable for the number of entries (and starters) among the higher grade cars. Not all of these came through the trial well, as many had very noticeable hard luck. Then, too, the lesser known cars came out in force, and many of them did surprisingly well, as witness the smaller Marlboroughs, the little Rileys, and the Little Britons. It is to be regretted that the final and official results of the fuel consumption tests of the last day are not known, so that the contest as a whole would be settled and consequent deductions drawn from the results.

One of the biggest surprises of the week, which has occasioned comment ever since as well, was the excellent performance of the 40-50 Gladiator, the highest powered and heaviest car in the list. The weight was well over two tons and the car stood right up in the van every day despite this. The double distinction of weight and power, coupled with the fact that it was alone in the highest priced class drew attention to the car at the outset, which was sustained later by its daily performances.

DIRIGIBLE AIRSHIPS OF FRANCE

PARIS, June 10—Orders have been given for the French dirigible balloon *Lebaudy* to be put to a series of gruelling tests. The airship, which was built in 1904, is to be put on active service and tested to its utmost limit, moving about with the troops and camping in the open air each night, its crew camping out with it.

M. Gustave Clement, the owner of the Bayard-Clement airship, has had a dirigible balloon shed built on a corner of the Issy-les-Moulineaux aeroplane ground in the neighborhood of Paris. This will give him a spot in which to house his airship after a journey from his country residence to Paris.

RACING AUTOISTS TAKE TO AERONAUTICS

PARIS, June 10—The automobile race movement, as it was known in Europe three or four years ago, having now become a thing of the past, crack race drivers are turning their attention to the aeroplane and seeking to qualify for positions as aerial racers. Although Henry Farman, the chief of the French aeroplane pilots, has not taken part in any important automobile race, he figured nevertheless somewhat prominently in the early automobile movement. His brother, Maurice, drove in big automobile races as late as last year, and is now experimenting with aeroplanes. Henry Fournier, a veteran of the automobile movement, and who has taken part in more international pure speed events than probably any other man, is already devoting his attention to the selling of aeroplanes, and has contracted for a large portion of the Voisin output this year. Further, he has had a machine built for his own use and, driven by a four-cylinder Itala motor, intends soon to make his first flights.

Baron de Caters, a distinguished figure during the race period from 1899 to 1905, when gentlemen race drivers were more prominent than professional chauffeurs, is a qualified aeroplane pilot, having made a number of very successful flights on a Voisin machine. Rougier, for many years a Dietrich race driver, and now interested in the sale of this car, has purchased an aeroplane and intends to take part in all open contests with it. His teammate, Arthur Duray, who, though a Belgian, first saw light in New York City, is also interested in the construction of an aeroplane, and may be expected to be heard of in the air very shortly. Victor Demogeot, the genial busy Frenchman, who has some fine records to his credit on Ormond-Daytona beach, is about to graduate from the automobile to the aeroplane, and will doubtless very shortly be announced as the pilot and demonstrator for a French company having a license to build Wright flyers. There are a score of others, who have been more or less prominent in the automobile racing movement, who are merely waiting the opportunity to take the wheel of an aerial racer.

Captain Hugh L. Willoughby, well-known in yachting circles, states that he is building an aeroplane in Florida.

THE AUTOMOBILE

WHY NOT AMERICAN WIRE WHEELS?

The unusual and continued success of the wire wheel on the other side, particularly in England, where they are much in vogue, draws attention to the fact that practically none is used in this country, the only maker having "stuck" to them in the past having now changed so as to offer wood as an option.

What is the reason for this apparent apathy on the part of the American public, always so attentive to foreign successes, toward the wire wheels? It is urged in their favor that they possess extreme light weight and much strength; in fact, weight for weight, it is possible to carry a much greater weight upon wheels of this type. Now the modern tendency is substantially toward the smaller car, with less carrying capacity, and, of course, light weight. Fuel consumption is becoming of much more importance each season, and increased useless weight means higher fuel consumption, without a doubt. Why, then, do not many of us arrive ultimately at the two-cylinder car with vertical motor of about 12-horsepower, selling below $1,000, and fitted with wire wheels?

Surely, if a car weighing perhaps 5,000 pounds and equipped with a motor of 75-horsepower, like the Napier, can go through season after season, on wire spoked wheels, without serious trouble, the efficiency and durability of this form cannot be questioned.

It is urged against the wire wheels that they have no strength to resist side strains, yet the little Cameron racer at the Savannah races last Fall stood practically upon two wheels with the other two in the air, while going along at the rate of sixty miles per hour, without any damage whatever, which does not sound very weak.

In England, where they attain their greatest popularity, a new detachable wire wheel has just been brought out, which seems to make that form even more popular than at present, if that is possible. Yet England is a great country for little and economical cars of 10 to 15-horsepower. If this form of wheel wears out as quickly as claimed, why is it that so many of the economically inclined Englishmen use that form?

Wood wheels have been the subject of study for perhaps one hundred years, and by a gradual process of elimination the faults have been reduced to a minimum. The so-called bicycle wheels, on the other hand, have been in existence not over one-fourth of that time. Who shall attempt to say, then, that with equal attention to materials, design, and construction, the wire form may not retrieve all of the faults laid at its door and become as efficient and as popular as its competitor, the older form?

One large item even now worthy of consideration is the great and growing trouble of obtaining suitable materials for the spokes and felloes of the usual artillery wheel. With wire, on the other hand, there probably never will be a scarcity of proper materials.

* * *

IN ORDER TO OBTAIN WINNERS

Never before have motor-driven vehicles been subjected to such vigorous and searching examinations as are now taking place throughout the entire country. Contests are scheduled in all sections, and rules have been originated for the sole purpose of reducing the field to a single winner in a class. Frequently even this fails to bring about an almost solitary survivor, and ties are not unknown in events calling for microscopic technical requirements. Mayhaps the officials are too insistent.

Coincident with the difficulty encountered in securing an elimination process that shall insure winners is the furtherance of knowledge on the part of the general public, which is rapidly learning to discriminate between demerit marks indicating faulty construction and those so minor in character as not to be entitled to any consideration in passing upon the reliability of an automobile. It is becoming generally recognized that the most minute attention in the compilation of rules is a necessity in encouraging competition, for the reason that tied scores bring about much dissatisfaction, and are naturally embarrassing to the promoting bodies in disposing of the prizes.

Hence, those concerns which in the past may have refrained from competition need not worry themselves in the least through fear of demerit marks which might interfere with sales. The average buyer now understands, and whether a car wins or loses the mere participation in the contest itself is an excellent recommendation as an indication of perfect willingness to try reliability with rival makes.

Judging from the generous entry lists, the agents are of the belief that contests aid in making a car known, besides assisting in accentuating and arousing widespread interest. Events indicate progress and prosperity.

HOW THEY WILL START IN CHICAGO RACES

CHICAGO, June 14—What was really the first official action following all the preliminary work leading up to the big road races took place on Friday last in front of the press stand of the Crown Point course. It had been proposed that the drawing should be by entrants rather than individuals, which meant that a concern with three cars should draw three numbers at one time, and the three cars be spread automatically down the list, and thus separated.

But Robertson and Strang objected. They pointed out that Savannah was the only one that had done it that way; that the Vanderbilt left it to individual drawing and that they preferred the Vanderbilt method. Willing to oblige, General Executive Trego left it to a vote and the vote favored Robertson and Strang. It was decided that the order of drawing should be by order of entering, which gave the Moon first draw in the Indiana trophy and the Buick first in the Cobe cup. Herewith is the result of the drawing:

COBE CUP

No.	Car	Driver
1	Stoddard-Dayton	B. Miller.
2	Knox	W. Bourque.
3	Apperson	J. Seymour.
4	Buick	L. Strang.
5	Stoddard-Dayton	C. Englebeck.
6	Locomobile	J. Florida.
7	Knox	A. Denison.
8	Apperson	H. Lytle.
9	Locomobile	G. Robertson.
10	Buick	L. Chevrolet.
11	Fiat	E. A. Hearne.
12	Buick	R. Burman.

INDIANA TROPHY

1	Corbin	A. Maisonville.
2	Buick	R. Burman.
3	Marion	H. Stutz.
4	Ford	G. Dunnell.
5	Chalmers-Detroit	W. Knipper.
6	Marion	A. Monson.
7	Locomobile	J. Florida.
8	Buick	G. DeWitt.
9	Fal-car	W. H. Pearce.
10	Locomobile	G. Robertson.
11	Moon	Phil Wells.
12	Renault	A. Greiner.
14	Buick	L. Strang.
15	Fal-car	J. Ruehl.
16	Stoddard-Dayton	F. Wiseman.
17	Chalmers-Detroit	Al Poole.
18	Stoddard-Dayton	C. Wright.
19	Chalmers-Detroit	J. Matson.

General Executive Trego moved his headquarters to Crown Point on the same day as the drawing, the Sheriff having given up his office in the county building to the road race official. Trego took possession and at once started to tackle the mass of details that confronted him. He heard the report of the surveyor who chained the course for the purpose of knowing exactly the distance around the circuit. It had been odometered at 23.6, and that distance had been used in talking of the race. But the steel tape told another story and reduced the distance materially. It showed the course to be exactly 23.27424 around, which, therefore, will make the little race 232.74 miles in length instead of 236, and reduces the Cobe cup from 402 to 395.66.

Plans for the ambulance service have been completed, two ambulances having been proffered for the work. One of them is a White steamer ambulance belonging to F. F. Roberts, a north side undertaker, who has agreed to equip it with a doctor and nurse. The other car also is a White steamer and is a combination touring car and ambulance, the idea of James E. Plew, of the White Company's Chicago branch. Ordinarily a touring car, the backs of the front seat fold backward, which makes either one or two comfortable cots in the tonneau.

A camp for the officials has been established, a unique idea that has been brought about by the skimpy hotel acommodations. The camp is located on the big 80-acre lot where the soldiers will pitch their encampment. Oliver G. Temme, bearing the high-sounding title of commissary general, is in charge of the officials' camp, and he has prepared accommodations for eighty, which will include forty of the flagmen who are working under the direction of Frank B. Wood. Tents galore have been erected, cooks and other servants hired and for the rest of the week the officials will live in comparative luxury while others are scouting around for sleeping and cating accommodations.

Eighty flagmen are being used for guarding the roads during the practice, which began Monday afternoon, forty of whom are students from the Chicago School of Motoring. It was found necessary to do the practicing in the afternoon because of the fact that the farmers of Lake County do a big milk business and they objected to closing the roads in the early morning, as is done in the Vanderbilt. They also objected to permi ting the practicing to begin on Thursday as originally scheduled, so the general executive issued the edict that not until Monday would the flagging service be instituted. This, however, did not prevent the drivers from becoming busy in the early morning hours, although they were somewhat handicapped by having to go slowly through both Crown Point and Lowell. Also the road was not completed all the way around, so this practice was generally unsatisfactory, although it did permit the drivers to study the road and be in a position to take advantage of this knowledge when they were turned loose and permitted to burn it. Arthur Greiner, the one amateur entrant, was denied this by a turn of hard luck. Just as he was preparing to move to his camp he was stricken with a touch of malaria, which forced him to go to the hospital instead of Crown Point, and for several days he chafed and worried while his rivals were stealing a march on him. Greiner was further handicapped by his unfamiliarity with the Renault which he is to drive. He got it only for this race and up to the time he went to the hospital he had not had a chance to drive it.

Officials chosen for the race show that the Chicagoans have endeavored to get the best talent possible. They selected Asa Paine, of Minneapolis, for referee, and Fred J. Wagner, of New York, for starter. Then they picked a home man for clerk of the course, Charles P. Root; Boston was called upon to furnish the chief timer, sending Harry Knights, whose reputation at this sort of work is national. The judges include John Farson, John C. Eastman and Fred D. Countiss, of Chicago; H. O. Smith, of Indianapolis; Judge W. C. McMahon, of Crown Point, Ind., and Judge V. S. Reiter, of Hammond, Ind. Frank B. Wood, of Elgin, Ill., is chief flagman, and "Bick" Edwards, of Chicago, has been given charge of the electric timing apparatus. The commissary general is Oliver G. Temme, of Chicago, who will have a competent staff of assistants.

WHITE IN GLIDDEN TO USE KEROSENE

The 40-horsepower White steamer which has been entered for the Glidden tour will make the 2,500-mile trip using kerosene as fuel instead of gasoline. This will be the first extensive public performance, either in this country or abroad, by a car using any fuel other than gasoline, and for that reason the progress of the car from day to day will be watched with unusual interest. The fact that this will be the only car entered by the White Company makes it evident that the company has the most complete confidence in the new kerosene burner and do not anticipate that any penalizations will result through the use of this new fuel. It might even happen that the supplies of gasoline shipped ahead for the use of the contestants on the tour will prove inadequate, in which case the White would have a decided advantage, as it could procure a supply of kerosene at any crossroads store or at almost any farm house. It is also evident that the cost of the fuel for the White throughout the trip will be considerably less than for any other machine. The car will be driven by H. N. Searles, who for two years was enrolled in the United States Secret Service and had charge of President Roosevelt's White cars at Oyster Bay.

CLEVELAND GETS A. A. A. GOOD ROADS CONVENTION

TWENTY-FIVE directors of the A. A. A. were in New York City last week attending the quarterly meeting of the association, held Thursday at the national headquarters, 437 Fifth avenue.

President Lewis R. Speare, of Boston, and several other directors remained until Friday morning to perfect some details in connection with the work of the various national boards. In speaking of the work accomplished President Speare laid especial emphasis upon the new racing and contest rules, presented by Chairman Hower of the contest board, which were unanimously approved, and the action taken to discourage the formation of purely promoters' automobile clubs, organized chiefly to hold race meets. It was resolved that hereafter the half rate price for sanctions to conduct meets allowed to clubs in the A. A. A. should not be granted to clubs which have not held A. A. A. membership for at least ninety days. The sentiment of the association's executive officers was very forcibly expressed to forestall race meets by "short-term" clubs in the future.

The new racing and contest rules drafted by the contest board and its advisory committee, composed of representatives of the manufacturers, will be printed and issued at once from Chairman Hower's office at Buffalo. Mr. Hower stated that thirty-two entries had been received for the Glidden Tour, and he told of the widespread interest that has been aroused in this year's event.

The Arkansas State Automobile Association was elected to membership, giving the national association its thirtieth affiliated State body. This association comprises clubs in Little Rock, Hot Springs and Fort Smith.

J. O. Heinze of the Lowell (Mass.) Automobile Club, T. Ed. Bryan of the Tampa (Fla.) Automobile Club, and A. J. Yeager of the Juniata Valley Motor Club, Lewistown, Pa., were elected directors.

A report was filed by Chairman Terry of the Legislative board regarding the work accomplished in many States, and interesting reports were also made by Chairman Diehl of the good roads board and Chairman Evans of the touring information board. Chairman Evans indicated that the activities of the touring information board had outgrown its present headquarters, and at his suggestion the president was authorized to appoint a committee to formulate plans for conducting the work of the board on a broader scale, and arranging for larger headquarters.

Chairman Terry of the committee on resolutions presented the resolutions indicative of the association's appreciation of the long continued interest and splendid service rendered by its former president, William H. Hotchkiss. The appointment by Chairman Hower, of T. A. Wright of Wilkes-Barre, Pa., and S. B. Stevens of Rome, N. Y., as members of the contest board was approved.

The members present at the meeting were:

President Lewis R. Speare, Boston; Frank B. Hower, Buffalo, chairman contest board; Powell Evans, Philadelphia, chairman touring information board; George C. Diehl, Buffalo, chairman good roads board; Charles Thaddeus Terry, New York, chairman Legislative board; E. P. Chalfant, representing A. L. A. M.; Treasurer H. A. Bonnell of New Jersey; Frank G. Webb, president Long Island Automobile Club; Robert P. Hooper, president Pennsylvania Motor Federation; O. A. Quayle, Albany; W. L. Brown, Syracuse; John O. Heinze, Lowell, Mass.; Dr. J. N. Faulkner, Paterson, N. J.; L. J. Powers, Jr., Springfield, Mass.; H. L. Hammersly, Wildwood, N. J.; S. Boyer Davis, secretary Automobile Club of Philadelphia; George A. Post, Paterson, N. J.; George H. Waters, Richmond County Automobile Club; Harlan W. Whipple, of New York; J. I. Wakelee, Englewood, N. J.; B. W. Nostrand, Peekskill, N. Y.; A. G. Batchelder, New York; W. O. Griffith, secretary touring information board; C. H. Gillette of Hartford, and Secretary Frederick H. Elliott.

A. A. A. Good Roads Convention in Cleveland

A meeting of the national convention committee followed the directors' meeting, and it was unanimously decided to hold the "Second Annual Goods Roads Convention" in the city of Cleveland during the last week of September. It was announced that George C. Diehl of Buffalo, chairman of this committee, and Secretary F. H. Elliott will shortly visit Cleveland, and while there confer with the officers of the Ohio State Automobile Association and the Cleveland Automobile Club relative to the naming of committees to take charge of the local work and make other arrangements for the holding of the convention.

Next Meeting of Directors in Detroit

It was decided to hold the next meeting of the A. A. A. executive committee in Detroit, Saturday, July 10, and upon the motion of President Speare the directors will be invited to attend the meeting. The association's officers will be guests at the banquet to be given on that evening by the automobile manufacturers of Detroit and will be guests at the Automobile Club of Detroit on Sunday and witness the start of the Glidden Tour on the 12th.

WISCONSIN GETS BETTER LAW

MILWAUKEE, June 14—The Wisconsin legislature has passed the Page bill, but amendments adopted at the last minute ruined the intent of the bill as desired by the combined clubs and associations of Wisconsin in eliminating the speed limit and making reckless driving under the circumstances a misdemeanor. The assembly amendment places a speed limit of 18 miles in cities and 25 miles in the country districts into the bill. The senate passed the bill as drawn, but in the assembly the rural members expressed the opinion that there was a "joker" somewhere in the elimination of the speed limit. The new speed limits are an improvement over the old provisions, which were: In cities, 12 miles, and country districts, 18 miles. The clubs are taking the compromise with good grace, as the opposition developing in the assembly was not unexpected. The Page bill also provides that no person under 16 years of age may operate a machine unless accompanied by a parent or guardian, and makes parties who fail to stop and offer assistance to any person injured guilty of a misdemeanor. It also raises the license of registration fee from $1 to $2 and abolishes transfers.

A HUSTLING SOUTH CAROLINA CITY

SPARTANBURG, S. C., June 14—In view of the proposed New York *Herald*-Atlanta *Journal* tour this fall from New York to Atlanta, a joint committee from the Greenville and Spartanburg Automobile Clubs, consisting of Thomas F. Parker, chairman, and W. J. Thackston, of Greenville; V. M. Montgomery and Fred. L. Bryant, secretary, of Spartanburg, and Frank Burgess, of Greers, was appointed to aid in the selection of the route through this section. The appointment of this committee was the result of a joint meeting, held recently in Greenville, which was attended by members of the Greenville Automobile Club, the Greenville Board of Trade, the Greenville county commissioners, committees from the Spartanburg Automobile Club, the Spartanburg Chamber of Commerce, the Spartanburg county commissioners, and a delegation of citizens from Greers. At this meeting there was much enthusiasm for the proposed tour, the county commissioners of both counties expressing their determination to put the roads in excellent condition before the time scheduled for the tour. While the routes are not definitely settled, each county will endeavor to have its best road used.

FAIRMOUNT PARK'S STOCK CAR RACE IN OCTOBER

PHILADELPHIA, June 14—At a meeting of the contest committee of the Quaker City Motor Club last week, it was voted, on the suggestion of Secretary Harbach, to devote the net proceeds from next October's 200-mile stock chassis race in Fairmount Park, to charity. To what particular purpose the funds so raised shall be devoted, will be decided upon at a subsequent meeting. Secretary Harbach has figured it out that if the sale of grand stand seats and parking spaces be placed in the hands of a committee of prominent society people, such as manage the annual charity ball, for instance, the proceeds of the race would reach $15,000 or $20,000. It was suggested that if the beneficiary selected should be the anti-tuberculosis league, the spectators, who would flock to the course by hundreds of thousands, as they did last year, would help along the fund by voluntary contributions, which, though small in themselves, would aggregate a substantial total. Collectors' booths, placed at each of the many entrances to the park, would attract the nickles, dimes, quarers and dollars of the public. Such is Secretary Harbach's idea.

The grand stand, which could be made as large as circumstances warranted, could be made to bring in at least half the large total mentioned, while the parking spaces would also sell for a substantial total, and the entrance fee could be placed at a figure which would insure handsome returns.

Given clear weather and a course patrolled and protected in the admirable manner which set a national standard for such affairs last year, and Quaker City society would put the seal of its approval on the affair, which would insure the race becoming an annual fixture.

NEWARK CLUB PLANS 1,000-MILE RACE

NEWARK, N. J., June 14—It is just barely possible that rivalry growing out of a tie in an endurance contest, and followed by a friendly challenge, may grow into a great big race of perhaps a thousand miles in length and appropriately staged by the New Jersey Automobile and Motor Club.

In the recent endurance run of the Mercer County Automobile Club at Trenton, both the Mercer, which is made in Trenton, and the Overland cars tied with perfect scores. The result of this was an extra run to determine the real winner. Not only was this not satisfactory to the car entrants and drivers, but it resulted in a challenge being sent and accepted.

The matter was laid before the board of trustees of the New Jersey Club at a monthly meeting, the upshot of which was that the contest committee was given power to act. Their first act was an application for a sanction from the A. A. A., and the second the selection and reservation of the mile race track at Long Beach. The date for the big event has not been settled definitely, but will be some time late in July or early in August, beginning on a Friday and continuing through to Saturday. On Saturday another track event, probably at ten or twenty-five miles or both, will be sandwiched in.

If the race is held at Long Branch, which now seems likely, the club will schedule a club run to the shore resort at that time, which will doubtless insure the success of the track race.

A 24-HOUR RACE AT BENNINGS

BALTIMORE, June 14—A 24-hour race meet will be conducted under the auspices of the Maryland Motor Car Racing Association July 16 and 17 on the mile circular track at Bennings, D. C. The event will be a twin city affair for the automobilists of this city and Washington.

The opening events will consist of two 5-mile, two 10-mile and two 25-mile races for stock cars. The 24-hour grind will start at half past eight o'clock, Friday night, and will be for stock cars of every description, both American and foreign make. This will be the first event of the kind held in this section of the country and the promoters believe that it is just the style of test that the people here are anxious for.

VICE-PRESIDENT SHERMAN WILL SET TIME

WASHINGTON, D. C., June 14—A sociability run to be given by the Washington *Times* on June 19 bids fair to be one of the most successful automobile affairs ever held in the national capital. The run will be to Great Falls, a picturesque spot on the upper Potomac River, which is reached via the famous conduit road. Secret time for making the trip will be set by Vice-President Sherman, who has frequently made the trip in his Peerless.

WHERE TRACK SPORT ATTRACTS

MONTREAL, June 14—Official announcement is made of the second annual automobile races under the auspices of the Automobile Club of Canada. The races will take place at Blue Bonnets race course, July 9 and 10, and the committee in charge of the races will at once complete arrangements to bring on the greatest auto racers the world has yet produced, including Christie, De Palma, Burman, Strang, Robertson, and others. A feature of this year's races will be the new car of Walter Christie, which he claims will smash all records. The car is 160-horsepower and has attained a speed of one mile in 27 seconds. Negotiations are being carried on to have F. J. Wagner, the starter of all the famous meets in America, including the Vanderbilt Cup races, to start the races here. The club is also endeavoring to secure an aeroplane, which will give demonstrations during each day of the races.

The committee appointed in charge of the races is: Clarence F. Smith, chairman; F. H. Anson, William Carruthers, and George A. McNamee, secretary-treasurer.

ATLANTA A MECCA NEXT NOVEMBER

SAVANNAH, GA., June 15—Having been obliged to postpone its three-day automobile race meet, Fritzgerald is now getting ready to have an endurance run to Atlanta, which will probably be held just before the opening of the automobile show in that city in November. The city has put up the sum of $1,000, to be awarded in the following manner to "best cars" and the "best roads": Five hundred dollars for the county offering the best roads between Fritzgerald and Atlanta, via Macon; $300 for the automobile making the best time during the run, and $200 to the second best.

Other cities that will have runs to Atlanta in November are: Albany, McRea, Dublin, and Savannah. Savannah has already offered $1,000 in cash prizes, and it is possible that each of the other cities will offer the same amount.

109 CONTESTANTS IN PRINCE HENRY TOUR

BERLIN, June 10—The contestants in the Prince Henry of Prussia automobile competition, which is being conducted under touring conditions, got away at five o'clock this morning from the Tempelhof road. One hundred and nine machines started at intervals of one minute.

Prince Henry came to the starting place in an automobile from Kiel. He did not remain, but went on to Gueben to observe the speed of the contestants on the way to Krossen. The entire course is 1,132 miles and will be covered in six stages. The stopping places are Breslau, Tatra, Budapest, Vienna, Salsburg and Munich.

NEW AUTOMOBILE CONCERN STARTS IN YORK

YORK, PA., June 14—Under the trade name of the Kline Kar, a new automobile will be produced in this city, manufactured by the B. C. K. Motor Car Company, the initials standing for Bailey, Carroll, and Kline. Application has been made for incorporation papers, naming the following as incorporators: S. E. Bailey, president, of Philadelphia, and of the York Carriage Company; vice-president, Joseph D. Carroll, of Fiss, Doerr & Carroll, of New York; secretary, J. C. Shutte, of S. E. Bailey & Company, Lancaster, Pa.; treasurer, George W. Ryan, York Carriage Company; designer and general manager, James A. Kline, formerly general manager of the York Motor Car Company. This concern has been formed as a result of the withdrawal of the interests held by Messrs. Bailey, Kline, and Shutte in the York Motor Car Company, the maker of Pullman automobiles.

A new factory has been built in the city, 300 by 50 feet in size, and to-day ground was broken for another building which will be 150 by 80 feet in size. About 300 men will be employed here, and the same number in the factory in Bath, N. Y., which has been purchased from the Kirkman Motor & Parts Company. The latter plant will be used by the new concern to make its engines, transmissions, rear construction, and other parts; leaving much of the machine work, the body building, finishing and shipping of complete cars to the York factory. Contracts are now being placed for materials with which to construct 500 automobiles, and Mr. Kline is completing designs for the cars.

STODDARD'S NEW CONCERN—THE COURIER

DAYTON, O., June 14—Inasmuch as the Dayton Motor Car Company of this city is working to the limit of its capacity to produce the Stoddard-Dayton automobiles, the officials of this concern have formed another one which will build a small car to sell for $1,000. The new organization will be called the Courier Car Company of Dayton, and its officials include C. G. Stoddard, president; H. J. Edwards, vice-president and designer of both cars; J. W. Stoddard, and a number of those connected with the Dayton Motor Car Company. The plant of the Kinsey Manufacturing Company, offering about 100,000 square feet of floor space, has been taken and machinery is now being installed. Work will commence about August 1, and inasmuch as both plants are near together, the official duties will be facilitated. The capital is $200,000.

The Courier will have a four-cylinder motor, of 3¼-inch bore and 4¼-inch stroke. It will be rated at 20-horsepower and will have a magneto. The transmission will be of the selective sliding gear type on the rear axle, the body will be a roadster or baby tonneau, and as stated the price will be $1,000. This will include full lamp equipment, and 3½-inch tires on 30-inch wheels. The plans and contracts for material call for an output of 1,000 cars.

AUTO ENGINEERS WILL MEET IN CHICAGO

NEW YORK, June 14—Chicago has been chosen as the meeting place for the midsummer session of the Society of Automobile Engineers, and the dates will be August 5, 6, and 7. This was decided upon at a recent meeting of the society council, and the dates selected so that they include that of the Algonquin hill climb, which the members may thus attend. From what Prof. Carpenter, chairman of the committee on papers, reported it appears that the discussions at the coming conclave will be of more value and general interest than those at any of the previous meetings. Those members of the council present were: Henry Hess, president; A. L. Riker and Thos. J. Fay, past presidents; Alexander Churchwood, secretary; A. H. Whiting, treasurer; H. M. Swetland, chairman entertainment committee; Prof. Rolla C. Carpenter, chairman committee on papers; B. D. Gray, and Henry G. Chatain, directors. Additional details of the meeting will be furnished at an early date.

WILLYS TO HEAD MILLION DOLLAR COMBINE

TOLEDO, O., June 14—Announcement has just been made that a million dollar company is shortly to be organized to bring about a consolidation of the various motor manufacturing concerns in which J. M. Willys, president of the Overland Automobile Company, is the chief figure. The company will form a holding company, which, it is stated, will be known as the Toledo Motor Car Company, and it will consist of a consolidation of the Pope Motor Car Company (recently purchased), the American Motor Car Sales Company, the Overland Automobile Company, and the Marion Motor Car Company, in all of which concerns Mr. Willys holds a controlling interest.

Bissell Company Will Make Electric Runabout

A jobbing company with F. E. Bissell of this city as president has just been formed for the purpose of handling a new electric runabout which is to be manufactured by the Bissell Electric Company of this city. The Bissell company at present handles only electric equipment of various kinds, but it has recently acquired patterns for a light electric which is to be placed on the market as both a low and medium priced machine.

CLAIM SERVICE IS NOT ECONOMICAL

WASHINGTON, D. C., June 14—The local post office authorities recently invited sealed bids for furnishing an automobile mail collection service. Seven hundred and seventy bids were received, and the announcement is now made that unless the Brush-Nichols Company, the present contractor for this service, makes a substantial reduction in the amount now paid for the service, its contract will not be renewed on June 30.

The Brush-Nichols Company is receiving $13,400 per year for furnishing three Brush cars with drivers, sixteen hours a day, in addition to which it is given, rental free, a garage estimated at $900 yearly. This service replaced ten foot collectors, whose combined salaries amounted to $10,000 per annum, and the postal authorities believe that the automobile service is not a sufficiently great improvement over that of the foot collectors to warrant paying the increased cost.

WARNER GEAR ABSORBS WARNER ELECTRIC

MUNCIE, IND., June 14—The Warner Gear Company, of this city, has just absorbed the Warner Electric Company, also of this place. The latter concern made control levers and emergency brakes which were marketed by the former, and as T. W. Warner was manager of both concerns, the transaction is in the nature of a consolidation. The Warner Gear Company will again increase its facilities, this time by 100 per cent, by new buildings and equipment. Building operations will begin within a few weeks. The concern employs 600 men.

THIS AUTO CALLED THE "SKIDDOODLER"

COLUMBUS, O., June 7—Because the application for licenses to operate automobiles in this State requires the name of the car to be given, J. Shrum, of this city, has designated his car as the "Skiddoodler." Inasmuch as he had constructed it himself of materials gathered or made by him, he could not name it by any of those applied by the manufacturers of autos. Therefore Mr. Shrum had to invent a name, and its number is "I."

APPERSON BROTHERS ENLARGING FACTORY

KOKOMO, IND., June 14—Additions of two three-story buildings are being made to the factory of Apperson Brothers in this city, and will be finished by the middle of August. These buildings will more than double the present size of the plant, and will give a capacity for 1910 of three times as many automobiles as have ever been made in any previous year.

SCHOOL TURNS OUT REAL CHAUFFEURS

Allurements of the profession of the chauffeur on the one hand, and of the desire for intimate knowledge of a newly purchased automobile on the other, have contributed primarily to the formation of automobile schools. Like the proverbial toadstools, a great many so-called places of learning arose in the earlier days of the auto interest, but these have disappeared on account of their laxity of management and curriculum, leaving several well established institutions of reliability. A school of the latter class has been recently organized in New York City by William H. Stewart, Jr., known as the Stewart Automobile Academy, and in general equipment and surroundings compares favorably with any of the best semi-technical schools of the country. With a corps of instructors who understand the automobile thoroughly from its practical side, as well as the theoretical, the students of this academy are given a course in practical operation of touring cars and roadsters. It is not the aim of any of the large institutions to give engineering courses or a deep technical knowledge of the cars, confining themselves to give a well-grounded insight into the whys and wherefores.

Stewart Automobile Academy Building

The demand for reliable chauffeurs continues, and from all over the country men are constantly coming to New York to be taught how to operate the increasing supply of autos. But the activities of the Stewart Academy are not confined to prospective chauffeurs, for a large number of owners have been enrolled, both men and women, who have recently purchased cars and have not cared to gain their knowledge through the hard lines of experience. The classes extend over a period of four or six weeks, according to the number of lessons taken during the week, and there are three sets of classes during the day: 9.30 a. m. to 12.30; 3 p. m. to 6; and 7.30 to 10.30 p. m. Special instruction is given for the women as best suits.

In the heart of the automobile district, on Fifty-fourth street, practically adjoining the Automobile Club of America, a building was secured last winter and thoroughly renovated, so that it became new to all purposes of the school. This structure is one of the largest occupied solely by an automobile school, having four floors and a basement, 25 by 100 feet in dimensions, giving 10,000 square feet of floor space, with an electric elevator large enough to lift the heaviest autos, wash stands, electric light and power, retiring rooms, offices, and of course, the laboratories. The windows are large and the result is that the entire building is bright and airy, and altogether suitable for use during the course of shop work or lectures.

Equipment of a modern nature is a prime requisite, and this important matter received ample consideration in fitting up the instruction rooms. Motors, transmissions, self-starting devices, ignition systems, carbureters, axles, springs, tires, and complete cars are included in the stock with which the embryonic autoist is made to understand. Blackboard lectures are also given, and the use of wall diagrams facilitate matters greatly, especially in regard to ignition requirements. When the student masters the intricate details of construction in the laboratories, road work is given and is not confined to running a machine through the parks or open streets, but right through the business and most congested parts of the city. For example, the last of the 12 driving lessons is to drive successfully a modern auto from the school to the Cortland street ferry and back, thus subjecting the operator to every conceivable test of city driving. The work on country roads is of minor consideration as compared to this. For this road work there are two machines used, a 30-horsepower Haynes and a 20-horsepower Locomobile. The former is a roadster, giving practice in the use of a car with jump spark ignition and shaft drive; and the latter is a touring car with make and break ignition and double side chain drive. On both of these cars there has been installed a double set of control pedals, brake and clutch pedals as usual for the driver, and a similar set for the instructor, so that in case of an emergency the car can be controlled by the latter.

In the laboratory there are several motors and other devices: a six-cylinder 1908 Winton motor; a 1908 Winton transmission; a 20-horsepower Locomobile motor in cross sectin for valve and igniter timing practice; a 1909 Oldsmobile four-cylinder motor; a 1908 Haynes chassis for practice upon chassis details, such as driving mechanism with the shaft drive, showing cardan joints, etc.; and a Locomobile chassis for similar work with a chain driven machine. The Winton and Oldsmobile motors are for actual running on stands, with the exhaust piped out of the room, and so arranged that various carbureters or ignition systems can be tried out. These integral parts of an automobile are of such nature as to be thoroughly representative, and a person who becomes familiar with them can be relied upon to understand any make. Each student is supplied with locker space, instruction books, and a kit of tools, so that there is no aspect of securing students for one fee and then subjecting them to other costs for supplies. In connection with the work in the laboratory, the lectures are carried on, with excellent ignition equipments for illustration. Carbureters are illustrated by popular types, and the same is the case with mechanical oilers. A

Corner of Stewart Laboratory, Displaying Wealth of Equipment

Another View, Showing Complete Chassis and a Few Motors

complete supply of various tires and rims is on hand to show the methods of the use of quick detachable, demountable, or regular clincher rims, repairing of inner tubes, etc.

When evident knowledge is instilled into the students a new tack is taken, that of trouble hunting, especially in regard to the finished motors. With an engine running regularly, a number of the class will be sent from the room, and some thing done to the engine which is likely to happen upon the road, and might puzzle the most expert. Water may be introduced into the carbureter, a valve or two may be fixed to stay open, the ignition wires may be mixed, the magneto timing deranged, or any one of a hundred different things done to confuse the autoist. The student must find this, and if he cannot do so alone, the instructor will aid him in following up certain lines of reasoning. Repair work is obtained on the upper floors of the Stewart building where outside trade is taken in, and the usual repair work done.

The officers of the Stewart Academy are: President, Richard E. Sause; vice-president and manager, William H. Stewart, Jr.; treasurer, Peter Cleary; secretary and assistant treasurer, Arthur V. Lyall; chairman of directors, F. S. Ferguson, Jr.; advertising manager, Harry S. Hall. The instructors are: Technical director, William H. Stewart, Jr., A.B., Rutgers College; internal combustion motors, C. T. Swart, M. E., Columbia; ignition, Stanley F. Bond, E.E., Columbia; motors and chassis, J. L. Del Rio, M.E., Columbia.

WHAT ONE OHIO CLUB IS DOING

COLUMBUS, O., June 14—The Columbus Automobile Club has started a department to furnish information to those who tour Ohio, with reference to the condition of the roads. The touring committee is receiving almost a dozen letters daily asking for information. The last consignment of road signs to cover Central Ohio has been received and will be erected as soon as possible.

CORBIN "TURTLE" DOES VERY WELL

At the recent Giant's Despair hill climb, the winner of the previous year and two-time holder of the Hollenback trophy, the Corbin car, was unable to compete because in practice the night before it turned turtle. As is well known to students of history, the turtle sometimes wins out, and this case was no exception to that rule, the Corbin making faster time in its only appearance of the day, in the last event, than did the winner of the Hollenback trophy race. Thus it was shown that had the car been able to compete therein, it would have repeated its victory of previous years, and finally won permanent possession of the cup.

Corbin Car Which Turned Over Without Breakage

A Modern Road Surface that Has Been Treated with Tarvia

ALLEVIATING THE DUST NUISANCE

Solutions of the dust problem in connection with automobile traffic, according to the report of Nelson P. Lewis, of the New York Board of Estimate and Apportionment, upon the recent International Road Congress in Paris may be divided into three classes. Of these the practicable one is to so construct and reconstruct the roads gradually, with binding materials which will make them proof against the disintegrating forces of high speed. The other two divisions considered are both impracticable, one being to require reduced speed and the other to build special roads all over the country. Mr. Lewis's report says in part: "It must be conceded that grit or stone dust of the same kind as that of which the road is built, or sand and mixtures of sandy loam and clay, are not suitable for roads as binding material, when freely used by automobiles. Only a perfectly homogeneous roadway, of which all the fine surface materials are protected against being scattered, is able to stand the passage of the extra rapid vehicles in use to-day. Either the roadbed must be so dense as to be unaffected, or a more vicious and elastic binding material must be used. It is quite generally believed that some form of bitumen is best adapted to this purpose."

Of the methods for reinforcing the binder of macadam roads, the French, English and American practice is frequently to select a prepared tar, no mention being made in the report of oils, soapy waters or other materials to suppress dust after it has been formed. It is recognized that the dust should be prevented from forming, if possible. In the United States a substance under the name of tarvia is available in three forms, suitable for various road conditions. One is very dense, sufficiently viscid to act as a binder, in the large voids of the 1 1-2-inch stone of a new highway; while for the top course, where the holes are smaller, a lighter article is manufactured; and for the minute pores of an old road, where there is to be no resurfacing, still lighter a fluid is supplied. In these cases the tarvia acts as a soft cement between the particles of stone, but, unlike cement in concrete, it does not become brittle, remaining resilient and waterproof.

Practice has seemed to indicate that under traffic a tarviated surface does not break up, but is rolled down and smoothed out, and consequently does not grind off any dust. At the same time dust which is blown upon the road adheres to it, is rolled into it and does not rise again. It is claimed that a single application of tarvia, in many instances, has produced dustless conditions for at least a season. Under light traffic a road so treated has remained dustless for upward of two years. In reporting upon the effect of tarvia on certain roads in the Borough of Richmond, Mr. Lewis says: "It has been demonstrated that at an increased cost, within the reach of any community, it is possible to secure a dustless road, incomparably better adapted than is ordinary macadam to automobile traffic."

GOODRICH TIRE EUROPEAN PLANT

PARIS, June 10—After France has sent her tiremakers across the Atlantic, the United States has replied by sending her experts to the old country. The first American tire factory in Europe is about to be opened near Paris by the B. F. Goodrich Company, of Akron, O. The firm has had a sales department in London for several years, and for the last two years has had a branch house in Paris, where French sizes were sold for French machines and American sizes kept in stock for the convenience of tourists. The president of the company, B. C. Work, is at present in Paris in connection with the projected factory, and expects to make a definite announcement regarding future plans within a few days. At the present time all tires are imported direct from Akron, the firm only maintaining a repair shop in addition to its selling branch near the Avenue de la Grande Armée. The Goodrich Company was the first American firm to sell tires in Europe, and will be the only one manufacturing on this side.

Havoline Oil European Plans for European Trade

It is more than probable that within a few weeks the Havoline Oil Company will enter on a business campaign with their products in France and other European countries. The agency for the company has recently been taken up by the American Auto Supply Company, and this week the manager of the company, A. E. Schwartz, sailed for New York with the object of arranging for a European business campaign on a large scale. The "Packard" brand of oil, now only offered at the Packard agency in Paris, will doubtless be on sale at all garages throughout Europe within a few weeks.

WELCH TO HAVE SMALLER CAR ALSO

DETROIT, June 14—The Welch Motor Car Company, long identified with the automobile industry as a producer of high-grade, high-priced cars, is about to enter a new field. Incidentally, Detroit's prominence in the automoble world is to be strengthened by the addition of another great factory.

W. C. Durant, of Flint, has purchased from the Olds Motor Works the property on Jefferson avenue it occupied when maintaining a Detroit factory. The purchase is understood to have been made for the Welch Motor Car Company, of Pontiac, which will next season put on the market a four-cylinder car of 24 or 30 horsepower, and selling around $3,000. An official of the Welch Company is authority for the statement that 1,500 of these cars will be made the first season, and that employment will be given to 1,000 men. Operations will begin about August 1.

It was at first rumored that the purchase had been made for the General Motors Company, which had also absorbed the Welch Motor Car Company. This is denied by officials of the latter corporation, who declare their concern will retain its identity, although the General Motors Company will market the lower-priced car. The new deal does not in any way affect the present Welch factory in Pontiac, which will continue to manufacture high-priced cars.

TO BUILD ELECTRICS IN WASHINGTON, D. C.

WASHINGTON, D. C., June 14—Electric delivery automobiles will shortly be manufactured in this city by the Pittsburgh Motor Vehicle Company. At a final meeting of the stockholders of this concern held recently, all the money necessary for the opening of a factory was subscribed, and the machinery is being purchased. It is expected that the plant will be in operation by the middle of July, although its site has not been announced. It is understood, however, that a location has been secured in the northwest part of city, within one block of Pennsylvania Avenue. The officers of the concern are: President, Arthur C. Moses; vice-president and general manager, W. H. Conant; treasurer, H. E. Leary; secretary, Stanton C. Peelle; directors, Byron S. Adams, R. P. Andrews, F. W. Bolgiano, Jules Demonet, A. F. Jorss and John J. Knox.

COLUMBIA MOTOR CAR COMPANY NEXT

HARTFORD, CONN., June 14—One more page has been turned in the affairs of the Electric Vehicle Company of this city, which has been in the hands of a receiver since December 10, 1907. The bondholders of the company through their legal representatives—Lucius F. Robinson, Albion B. Wilson, and Francis W. Cole, all of Hartford—to-day filed with the secretary of state a certificate of incorporation of a new concern to be known as the Columbia Motor Car Company of Hartford. The new company will take over and acquire all and any assets and property, real and personal, of every kind and description of the old concern, that is, the Electric Vehicle Company. The authorized capital stock of the Columbia Motor Car Company of Hartford is $48,000, divided into 480 shares at a par value of $100 each. Of the capital stock, $32,000 represents preferred stock or two-thirds of the capitalization, while the remaining one-third represents common stock.

Before the property of the Electric Vehicle Company can be acquired by the Columbia Motor Compay the necessary power to sell must be granted the receivers by the courts of New Jersey. As already mentioned in last week's issue, the receivers have applied for the right to sell to a committee of reorganization, and the court order is returnable on Tuesday.

Just what the policy of the new company will be is not known and nothing is said or can be learned of it at this time. However, it is the accepted belief that the manufacture of Columbia gasoline and electric models will be continued as heretofore by the receivers. At present the 29 hp. four-cylinder car is the only gasoline model built by the company. It is stated on good authority that next season the company will bring out a six-cylinder motor with the same stroke and bore as the present, but having a dual system of ignition.

The May report of H. W. Nuckols and H. M. Barrett, receivers of the company, shows sales during the month of $78,411.53. Of the cash receipts, $3,630.48 was realized from the Selden patent, and of the disbursements George B. Selden is credited with $37,729.55 and the Licensed Association with $3,395.20. The balance on hand June 1 was $169,599.50.

NEW WIRELESS SYSTEM OF UTILITY

AKRON, O., June 14—Ever since the incident of "Jack" Binns and the ill-fated *Republic*, the people have been greatly interested in any sort of "wireless." The latest, which has just been announced here will interest automobile owners, and particularly truck owners, more than the general public. This is a new form of tire just brought out by the B. F. Goodrich Company.

The new "wireless" tire is meeting with such favor among manufacturers of motor trucks, that the demand for them is already exceeding the ability of the huge Goodrich factory to supply them. The immediate reasons for its success, as set forth by the manufacturing company, are certain advantages which are enumerated as follows: First, increased mileage, because the tire will stand a maximum external abrasion without affecting its fastening to the wheel; second, freedom from repairs, because there is no hinging action of the rubber over internal metal fastenings; third, decreased cost per mile, as a result of the first two advantages. No complicated machinery is needed to apply these tires, and they may be readily put on to any wheel which has been equipped with a "wireless" rim.

The "wireless" dual type offers perhaps the most unique advantages. The improved construction makes it possible to set the twin tires on the rim in direct contact with each other. This reduces the space between the tires to the minimum necessary to prevent skidding and displacement of the rubber under stress. The narrower tread also reduces the necessity for offsetting the felloes on the drive side, and enables the load to be distributed centrally over the hub and spokes.

Marshalltown, Iowa.—Ingval & Rhodes have let contracts for the erection of a new garage which will cost $6,200, to be built of brick and cement, on East Lincoln street.

Hopewell Cutting Room, Cutting Machine in Action

TIRE CASES REQUIRE ACCURATE WORK

To manufacture cases for tires is no longer a hit-or-miss trade, but requires mathematical accuracy in the measurement of the goods, in the assembly, and finishing, in order that the protectors fit the tires perfectly. The Hopewell Brothers, of Cambridge, Mass., are among the largest makers of tire and lamp covers in the country, and they have shown the realization of the need for care in the producing of their output. The concern is a partnership between Frank B. Hopewell and Charles F. Hopewell, the former having invented the Hopewell tire case, and the latter having taken charge of its development. These men have patterned their cases from the rim dimensions entirely, for they claim that the measurements of tires vary as much as half an inch in outside diameter, thereby preventing a good fit.

In the factory the accuracy of cutting is obtained by electric machines which run at 3,500 revolutions per minute, are capable of cutting 50 thicknesses of goods at one time, and they must do this within one-eighth of an inch of the exact measurement or the cuttings are not accepted by examiners. With two tables of electric cutters, 300 tire cases can be turned out at a time. After this operation the goods are taken to a machine room, which is equipped with 32 machines able to stitch very heavy material, and when the sewing is completed, the cases are given a rigid inspection. They are examined for workmanship, material, dimensions, and the circumferential measurement must be accurate to within one-quarter inch, or the case is rejected. Between 1,500 and 2,000 cases are carried in stock, all neatly packed in boxes. The springs which are used to make the cases fit snugly around the tires are all tested for elasticity and strength of joint, and are japanned before being used. Nearly a ton of these steel springs are used weekly, and several miles of goods are required. Lamp covers and other lines of goods are given the same care in material and workmanship as the Hopewell tire cases.

In the Machine Room Where Numberless Girls Sew Cases

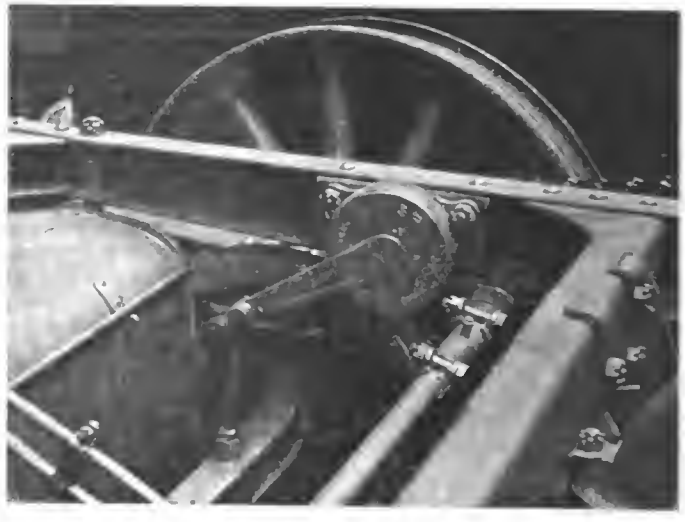
The office system has been given great consideration by the company, so that at present by cross-indexing, and the use of card catalogues, the orders may be found instantly, and are thereby assured of more prompt and careful attention than when no definite rules are followed.

LATEST IN FRENCH SHOCK ABSORBERS

PARIS, June 10—An exceedingly simple and efficient type of shock absorber has just been placed on the French market under the title of The Sphinx, and adopted as a standard equipment for all cars of one of the leading French makes. The apparatus consists of two cylindrical boxes, one of which is bolted to the side member of the frame, and the other, with lever integral

Sphinx Shock Absorber Dismounted to Show Parts

with it, forming a cover free to pivot round the fixed member; the two are attached by means of a simple type of bolt and nut forming the axis of the pivoting member. The fixed box contains three concentric rings, each one lined with felt and a steel spring forming eccentric. On the pivoting member are three



Fitted to the Rear Axle and Frame of a Car

wedge-shaped studs fitting into the grooves formed by the rings. When the car is at rest the studs are lodged in cut-away portions of the spring and felt lining with just sufficient play to prevent them coming into operation for slight oscillations of the chassis. An increased movement of the frame in relation to the axle causes the studs to be forced into the grooves formed by the rings, and the further they travel round the greater is the resistance, thus, of course, tending to eliminate violent oscillations of the chassis.

How to destroy battleships from airships is to be shown by the Wright Brothers when they finish the Government tests with their aeroplanes at Fort Myer next June. The outlines of a battleship will be made on the ground with chalk and projectiles will be dropped from the airship.

A Mission Type that Prevails in Southern California

GARAGE THAT HAS A NOTED CLIENTELE

SANTA BARBARA, CAL., June 11—The Higgins Machine Works Company, which conducts the principal garage in this city, lays claim to having housed the cars of more American notables during the past four months than any other garage in the country. To substantiate the claim, a list has been prepared of notables who have been at the garage with their cars since the first of the year, viz.:

E. H. Harriman, New York, president Southern Pacific Railway; E. P. Ripley, Chicago, president Santa Fe Railway; Louis F. Hill, St. Paul, Minn., president Great Northern Railway; James Hobart Moore, Chicago, president Rock Island system; John Hays Hammond, world famous mining engineer; W. F. Dreer, Philadelphia, leading seed merchant; George J. Haime, St. Louis, capitalist; D. D. Walker, St. Louis, capitalist; General Henry Strong, Chicago, former attorney general of Illinois; Penticost Mitchell, St. Paul, United States Steel Company; J. V. Silverson, New Ulm, Minn., president Eagle Rolling Mills; R. B. Merrill, Seattle lumberman; P. B. Stewart, Colorado Springs, capitalist, cousin of ex-President Roosevelt; Mrs. Nelson Morris, widow of the Chicago packer; A. Chester Beatty, New York capitalist and mining engineer; former United States Senator Baird; Judge W. G. Henshaw, Oakland; A. P. Knight, Denver, painter and personal friend of King Edward; Thaddeus Welch, one of America's greatest landscape painters; Stewart Edward White, author; Lloyd Osborn, author; Mrs. Robert Louis Stevenson, widow of the poet; William Miller Graham, oil king; C. B. Hale, New York capitalist; A. G. Spalding, Chicago capitalist; W. H. Cowles, Spokane capitalist, related to Mrs. Theodore Roosevelt; R. T. Crane, Chicago, president of Crane Company, steel and iron; W. E. Sloan, New York capitalist; Captain Huron Rock, Canadian capitalist; Louis F. Jones, New York capitalist; S. P. Calef, New York capitalist.

This list does not show all who have come here during the past months, but just such as have had their own cars at this garage.

A GARAGE OF ELIZABETHAN ARCHITECTURE

CINCINNATI, June 14—Different from the general run of garage buildings, the new garage of the Robert C. Crowthers Automobile Company, at the junction of Mitchell and Clinton Springs avenues, Rose Hill, Avondale, will be in keeping with the residential surroundings of that popular suburb. The property was leased by the Crowthers Company for a term of years and it is suitable for housing 25 to 30 automobiles. Mr. Crowthers will occupy one end as a residence and will reserve a fine large room separate from the garage proper for a salesroom. Royal Tourist and Elmore cars are handled in addition to doing a general garage business. The opening of this new place in the midst of Cincinnati's residence district has proven very popular with automobile owners, who were compelled previously to keep their cars at inconvenient distances.

ABOUT GARAGES THE COUNTRY OVER

Atlanta, Ga.—One of the largest vacant tracts of land in the business part of the city, on Auburn avenue between Courtland and Piedmont, has been sold to John M. Smith, a carriage manufacturer, upon which one and perhaps two garages will be erected. The lot has a front of 86 feet and it is 375 feet deep. There has been a tendency of late to make Auburn avenue the Automobile row, and already the Maxwell and Oldsmobile interests have located there.

Columbia, S. C.—At a total investment of about $18,000, E. A. Jenkins will within a short time begin the erection of a building for the Jenkins Automobile Company. A lot at the corner of Main and Richland streets has been purchased for $9,500 and upon it will be constructed a garage, sales room, and office structure, 40 feet wide and 120 feet deep, from which will be sold the White, Stoddard-Dayton, and Reo cars.

Los Angeles, Cal.—A one-story brick garage, 150 by 140 feet in size, is being built at the corner of Tenth and Olive streets. It has been leased to the Stoddard-Dayton Motor Company for a term of years. The interior finishings of the salesrooms, offices and other quarters will make the building one of the handsomest of its kind in this part of the country. It will cost about $15,000.

Portland, Me.—Excavations have been commenced for the building of a large garage and salesroom on Forest avenue. The building will be 80 by 133 feet, two stories in height, and will be completely equipped for a modern garage, with salesroom in front, and elevators permitting of the use of the basement for storage of cars. The second floor will be used as a skating rink.

Baltimore, Md.—At an expense of about $25,000, Michael Griffin will erect a three-story fireproof garage at Howard street and Park avenue. Plans have been drawn and the contract already awarded. The building will have a 98-foot front and a depth of 75, constructed entirely of brown stone, granite and concrete. The floors will be of tile work with fancy designs.

Blacksmith Shop Now a Garage—The trend of the country blacksmith toward being an automobile repair man is a recognizable one, and the town smithy has followed suit. In Fulton, N. Y., W. T. Fuller has sold the building which he has used for a blacksmith shop for many years and it will be converted into a garage.

Lexington, Ky.—The Phoenix Garage has amended its articles of incorporation to change its name to the Phoenix Motor Car Company, with an increase of stock from $10,000 to $15,000. The articles are signed by A. L. Hamilton, V. K. Dodge and N. W. Dodge, directors.

Denver, Col.—The Denver Omnibus and Cab Company will have a new stable and garage, to be immediately erected at a cost of about $150,000. It will occupy half a block on East Eighteenth street, between Pearl and Washington streets.

Wilmington, Del.—The Wilmington Automobile Company has arranged to have an $8,500 addition made to its garage on Tenth street. The new part will be at the rear, extending back to Hamilton street.

Princeton, Ky.—A garage has been opened in this city by Raymond Frazier, who was formerly in the automobile business in Evansville, Ind.

Plainfield, N. J.—The Morris Auto Company has arranged for an addition, 50 by 100 feet in size, to its garage.

Rose Hill Garage, Cincinnati, a Southern Ohio Masterpiece

News in General

Winnipeggers Buy Many American Automobiles

Above is shown a single shipment of Franklin air-cooled cars recently received by the Winnipeg Garage, Ltd., which represents the Syracuse manufacturers throughout Manitoba and Saskatchewan. This is the second shipment of these cars in the year and shows plainly the growing use made of the automobile in this faraway and unfamiliar country.

Electric Welding Products Company Enlarges—Growing demand for the parts manufactured by the Electric Welding Products Company, of Cleveland, has necessitated an increase in its facilities. The factory was worked overtime all last winter, but was unable to catch up, so a large addition was built and has just been completed. This is a three-story structure, which will nearly double the capacity of the plant, and it will handle the gas engine and automobile parts, such as combination valves, solid and tubular propeller shafts, gear blanks, truss rods, grip control and brake levers, and special steel screws. About 20,000 square feet extra space were secured and it is stated that some new products will appear this year.

You Can't Steal That Car—It would make anybody peevish to have his car stolen; yet that is such a very easy thing to do with the ordinary automobile that the manufacturers of the Rambler have devised a lock, which from now on will be applied to their entire output. This is in the nature of a key in the gasoline pipe, without turning which the fuel may not flow to the engine, and, like the gasoline gauge, which Thomas B. Jeffery & Company are fitting to all cars, it is not in sight until wanted, and then is immediately useful.

In Truth, These Were Jewels—After completing the strenuous tour from Denver to Mexico City, in the Chalmers-Detroit "Flag to Flag" pathfinding car, reports William Knipper, two of the Diamond tires still contained the original air, one had suffered but one puncture, and the remaining tire but two. The weight carried on the 34 by 4-inch tires was 3,850 pounds, in view of which their performance was remarkable.

Quick Change Made with Doolittle Rim—In the three-day tour of the New York Auto Trade Association, the Interstate car was equipped with Doolittle demountable and quick detachable rims, and near the finish this equipment proved its worth. The car had a puncture at 136th street, just as another contestant passed it. The tire was changed in about two minutes, and at 103d street it caught and passed the other contestant.

New Auto Factory for Millville, N. J.—It is likely that an automobile manufacturing concern will shortly locate in Millville, N. J., according to statements of the local board of trade. The name of the concern is not announced, but it is said to have stated that should it be able to purchase three acres of ground at a reasonable figure it will locate there. Three property owners have offered to donate the land.

Carbureter Business Looking Up—The general improvement in business has extended to the automobile accessory manufacturers to such an extent as to require additional factory facilities. The latest to build an addition is the Kokomo, Ind., firm of Byrne, Kingston & Co., which has just contracted for the erection of a two-story brick building, 60 by 132 feet in size, to be devoted exclusively to Kingston carbureters.

Another Victory for New Departure Bearings—The recent victory of the Allen-Kingston car in its class events in the Dead Horse hill climb is recorded by the makers of New Departure ball bearings as another victory for those bearings, which are used in the A-K automobiles. This car made the fastest time of all gasoline stock cars in the meet, 1:07 4-5.

Belmont Car from Castleton, N. Y.—Automobiles to be sold under the trade name of Belmont are to be built by a company in Castleton, N. Y., of which H. H. Ingalls is president, and A. C. Cheeny, secretary and treasurer. The factory will be located upon the grounds of the A. C. Cheeny Piano Company.

Gearless Creditors File Bankruptcy Petition—The creditors of the Gearless Motor Car Company, of Rochester, N. Y., have filed a petition in bankruptcy against the concern in the United States Court at Buffalo. According to the petitioners the company has admitted its condition.

McCord Begins Factory Addition—Ground has been broken in Detroit by the McCord Manufacturing Company for a factory addition that will enlarge the present plant by 40,000 square feet. It will be ready for occupancy in 40 days and will nearly double the output of radiators, lubricators and gaskets.

TAXICABS AND TRANSIT

Automobile Transportation for the Igorrotes—Over a distance which formerly necessitated a trip of ten in the Philippines, from Manila to Baguio, automobiles now have a route which is covered in eleven hours. The government has expended $2,500,000 on the road and the postal department has placed in operation five cars, each carrying seven persons, mail and light baggage, between Baguio and Camp I. The former place has become a resort and many Manila residents have built houses there, the season lasting from March 1 to about June 15.

Montreal Hack Drivers Protest—Because horse-drawn, see-going hacks are much more comfortable than the atrocious taxicabs, the drivers of the city of Montreal have petitioned the police committee to prohibit the importation of the dangerous machines. A goodly number of signatures of the handlers of the reins have been affixed to the document, setting forth their objections, claiming, among other reasons, that the taxicabs make money only when running fast and that the streets are too narrow for speed.

Big Taxicab Concern to Start in New York—The Gotham Taxicab Company is preparing to start a large business in New York City, beginning with 50 cabs, on August 1, and gradually increasing that number. The plans have been made for a new style of cabs and the rates will be 30 cents for the first half mile and 10 cents for each quarter of a mile thereafter. The officials are: President Edward J. Dowling; vice-president, John V. Levy; secretary-treasurer, S. L. Root.

Auto Line to Complete Texas Gap—A gap of 53 miles between two railroad

New Home of Empire Tires in Chicago

connections will probably be instituted between the towns of Mary Neal and Tennyson. The Orient railroad, it is reported, will start a train service between San Angelo and Tennyson, 20 miles out, and at the same time start a train between Sweetwater and Mary Neal, leaving a gap between Mary Neal and Tennyson which, during the month of June, will likely be covered by autos.

Autos Meet Trans-Atlantic Steamers—Combining the pleasures of a sea voyage with those of an overland trip in an automobile, reserved by means of the wireless telegraph, is a plan recently put into effect by the Compagnie Generale Transatlantique (French Line). Its fastest mail steamers may be met at Havre by De Dietrich automobiles for the run to Paris, a five-hour journey with a stop for luncheon at Rouen.

To Operate Cabs in Asbury Park—S. A. M. Thompson, who is the vice-president of a taxicab company, is looking for a suitable location in Asbury Park, N. J., for the erection of a taxicab garage or for securing one already built. The concern proposes to operate a large number of machines from the Jersey coast resort to neighboring towns.

Ironton, O.—An automobile line between Ironton and Proctorville will probably be established as soon as the authorities at Coal Grove repair a stretch of bad road. A fourteen-passenger 'bus will be used, owned by S. G. Griffith, of Huntington, and will make two round trips a day.

IN AND ABOUT THE AGENCIES

Chalmers-Detroit—The sales department of the Chalmers-Detroit Company announces the following agents, with whom contracts have been made to handle the 1910 Chalmers-Detroit: Los Angeles, Cal., Western Motor Car Company; Hutchinson, Kan., Taylor Motor Company; Sioux City, Ia., Wetmore & Rogers Auto Company; Baltimore, Md., Zell Motor Car Company; Cincinnati, O., J. H. Ratliff Auto Company; Chicago, Levy & Hipple Motor Company; Zanesville, O., C. A. Fritz; Savannah, Ga., T. A. Bryson; Hastings, Neb., Stitt-Dillon Motor Company; Catlettsburg, Ky., O. C. Magann.

Firestone Tire and Rubber Company—The new Cleveland Firestone branch, located at 1918-1922 Euclid avenue, is one of the handsomest establishments along that city's famous Automobile Row. A unique characteristic of the new store is

Handsome Firestone Store in Cleveland

the private garage in the rear that will accommodate three cars, where motor truck or pneumatic automobile tires may be changed under shelter.

Empire Tire Company—The Chicago branch, of which E. B. McKay is manager, has been moved to 1305 Michigan avenue, from 20 LaSalle street, in order to facilitate the demands of the company's rapidly growing business. As will be seen by the illustration on the opposite page, the building is commodious and well adapted to the needs of a live and up-to-date concern.

PERSONAL TRADE MENTION

Arthur L. Banker, a pioneer automobile agent of Pittsburgh, Pa., has returned to the selling business as sales manager of the Banker Brothers Company, handling the Chalmers-Detroit and Hudson cars. About six months ago he left this concern to organize a wind shield company to use his patents, known as the Banker wind shields. A number of the large manufacturers have ordered this equipment for the coming season, and the Pierce-Arrow Company will manufacture 1,200 under the Banker patents for 1910.

Puller Harper, of Pittsburgh, will shortly enter the automobile business on his own account in New York City. He has been in the same business in this city lately and was formerly connected with the Westinghouse Company at East Pittsburgh.

T. W. Warner, general manager Warner Gear Company, Muncie, Ind., sails for a two months' trip in Europe June 24, on the Hamburg-American liner Graf Waldersee. During his absence Ray P. Johnson, treasurer, will have the active management of the plants.

David Bruce Brown, the amateur autoist who has broken many records this season at the wheel of the 120-horsepower Benz, will sail on Saturday for Europe. His trip is a pleasure one, and he will visit a number of the large automobile factories.

Orlando F. Weber has been appointed manager of the Chicago branch of the Palmer & Singer Company. Mr. Weber was a former cycling champion and has been connected with the Pope interests.

Frederic Thomas Bailey, familiarly known as "Harris Oil Bailey," has issued cards announcing the birth of Frederic Thomas Bailey, III, at Lake Forest, Ill., on June 2.

RECENT BUSINESS CHANGES

Kokomo Rubber Sale Off—Grafton Johnson, the Greenwood, Ind., capitalist who put up $25,000 as an option on the plant of the Kokomo Rubber Company, Kokomo, Ind., failed to pay the required $725,000 additional before his option expired, and as a consequence the rubber company paid its stockholders an extra dividend.

Kirkham Changes—Control of the Kirkham Motor Manufacturing Company, Bath, N. Y., was recently changed, when S. E. Bailey, of Philadelphia; James A. Kline, of York, and Joseph D. Carroll, of New York City, obtained a majority of the stock.

NEW AGENCIES ESTABLISHED

Interstate: Harrisburg, Pa.—Motor Vehicle Company, for central Pennsylvania, in addition to the Jackson.

Regal: Atlanta, Ga.—A. S. Allen, 102 North Pryor street.

Regal: Springfield, O.—E. D. Valentine, King Garage.

Studebaker: East Orange, N. J.—Herbert E. Listman.

RECENT INCORPORATIONS

Capital City Auto Company, Austin, Tex.—Capital $7,500. To operate taxicabs, maintain garage, and deal in automobiles and accessories. President, Pierre Bremond; vice-president, E. H. Perry; secretary and treasurer, R. M. Thomson, Jr., agent for the Pierce-Arrow, Oldsmobile, and Oakland.

Couple-Gear Company of New York, New York—Capital $50,000. To manufacture motor vehicles, electric and other motors, cars, carriages, and vehicles. Incorporators: W. H. Kennard, F. B. King, Howard Greene.

Cleveland, Beck & Layman Motor Corporation, New York—Capital $8,600. To manufacture motor boats, vehicles, motors, cycles, etc. Incorporators: Chauncey Cleveland, A. L. Beck, H. B. Layman.

Tobin Whichway Signal Company, New York—Capital $300,000. To manufacture automobile supplies, lamps, signals, etc. Incorporators: W. M. Wherry, Jr., C. A. Brooks, Frances Murphy.

Walden W. Shaw Auto Livery Company, Chicago—Capital $300,000. To manufacture and deal in automobiles and other motor vehicles. Incorporators: E. N. D'Ancona, N. E. Dugan, A. J. Pflaum.

Newcomb Engine Company, Harrison, N. Y.—Capital $200,000. To manufacture motors, engines, automobiles, boats, launches, etc. Incorporators: W. B. Thompson, O. A. Hack, E. C. Chamberlain.

Mercer Automobile Company, Trenton, N. J.—Capital $500,000. To manufacture automobiles, wagons, etc. Incorporators: F. W. Roebling, A. R. Kuser, J. L. Kuser.

STEWART TREBLES PLANT

About ninety days ago a large addition to the factory of the Stewart & Clark Mfg. Co., Chicago, was completed, and now work has been started on an addition that will treble the present size of

How the Enlarged Stewart Plant Will Look

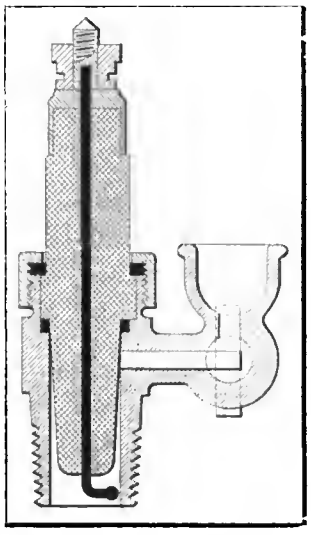
the plant, with a corresponding increase in capacity. Demands for the Stewart Multipolar speedometer have been so pressing that, although the present capacity of the plant has been taxed to its utmost, it has been almost an impossible task to fill orders. The company will be in excellent shape to handle the volume of 1910 business expeditiously, and the illustration shows how the factory will look when the new addition is completed.

RECENT PUBLICATIONS

Harry S. Houpt Company, New York—Illustrative of Herreshoff automobiles, "the smart, light cob of motor cars," the Harry S. Houpt Company, of New York City, has recently issued one of the most attractive catalogues seen this year. The frontispiece is water color reproduction, which sets off the front of a Herreshoff car to advantage in an outdoor picture, and the two photographs of the cars, touring and roadster, are examples in their line. The wording of the matter in the booklet is altogether pleasing and apt to be read because of interest, even by a casual observer. The reasons for the manufacturing of a small car to take the place of large expensive ones in city or suburban service is well brought out, as are also the claims which can be made for Herreshoff construction as represented in automobile engine and motor boat design. The byword of the early announcements, "correct interrelation of parts," is amplified, detailing the theories used in the design of the small auto. The specifications are placed in an easily read tabulated form, and the motor, transmission, axles, brakes, steering gear, and other important particulars illustrated with wash drawings.

Information for Auto Users

Combination Plug and Relief Cock—Many an autoist has "cussed" his engine because the construction was such as to require the removal of the spark plugs, when priming was in order. This necessity is obviated by a new plug, which carries on one side of the stone a large opening leading to a regular relief cock. The latter does double duty in that, aside from use as a compression relief and priming cock, its use when the engine is running cleans off the sparking points. This is effected by so shaping the circular opening leading to the outer air through the cock that the gases from the cylinder must pass over the points. As these gases are always under high pressure, the points are effectually cleaned off. The use of this plug also adds to the ease with which misfiring cylinders may be detected. It is made by the Comet Electrical Mfg. Co., Detroit, Mich., and is aptly named the All-In-One spark plug. Up to date it has been used on a number of racing motor boats on the Great Lakes with the best of success.

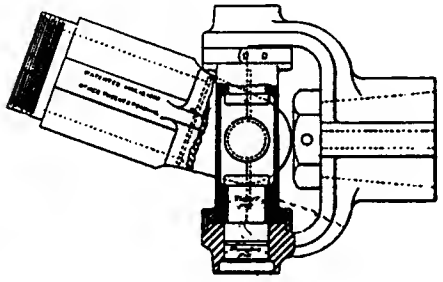


ALL-IN-ONE SPARK PLUG.

A Decidedly Different Carbureter—Since the birth of the automobile there have been attempts without number to solve the problem of carburetion, and it is not solved yet. A recently brought-out device introduces some new features which are of great interest, as being very practical, as well as novel. In the Bennett carbureter, made by the Wilcox-Bennett Carbureter Company, Minneapolis, Minn., the variation from the standard lies in the substitution of a standpipe for the ordinary spray nozzle. This standpipe has a large number of holes drilled along the sides, which, as set in the actual device, are vertical. Thus, when the running speed is very low, and the engine suction correspondingly weak, fuel is drawn but from one of the holes, the bottom one. As the speed increases and with it the suction, gasoline is drawn from more holes than the first, the number depending upon the pull of the motor. This effect increases until the greatest possible suction may be drawing from every one of the numerous holes, and in this way the engine is getting the maximum amount of fuel needed at that speed. The air control is through an auxiliary air valve, its action being controlled by a spring, the tension of which may be regulated from the outside without disturbing any other part. The number of holes which will be contributing fuel at the highest speed is, of course, controlled by the amount of gasoline allowed to enter the standpipe, and this may be changed or regulated at will by means of the needle valve head. This is milled and projects above the central part of the carbureter body, so as to be very accessible.

New Asbestos Brake Lining—Now that automobile brakes are receiving the attention which they deserve at the hands of designers, there is more demand for suitable brake lining material. One of these, possessing much of worth, is the product of the Empire Tire Company, Trenton, N. J. This material is composed of a central or major portion of asbestos, covered with an envelope of rubber. The fiber used is long, staple asbestos, closely woven, this having the high wear-resisting qualities which the short and coarse staple cannot have. The rubber coating, having no wear-resisting qualities, is made as thin as possible, its function being simply that of a holder which retains the asbestos together. By putting this rubber on the asbestos under an hydraulic vulcanizing pressure of close to 2,000 pounds per square inch, a very thin coating is insured. In this manner the percentage of useful material to total is made very large and the buyer gets the most for his money. The maker's confidence in the product is shown best in the test which is given. This is to select two or more samples of equal width and thickness, weigh, burn, and weigh the residue. The difference in weight shows the useless material, as asbestos will not burn.

Simple and Strong Universal Joint—Simplicity is always desirable, and more than usually so in a part which is subject to varying and severe strains. Thus the new universal joint put out by the Mutual Machine Company, Hartford, Conn., is particularly meritorious because of its unusual simplicity. The parts of this joint are all drop-forgings from a high grade of steel. The design is such that no cotter pins, nuts, bolts, screws, or other sources of trouble are used in the construction. In this way not only does simplicity make for natural superiority and increased strength, but the owner and driver is assured more peace of mind, in that he does not have to think of the parts which might come loose and rattle off. The interior of the main block is filled with grease, the opening being large enough to carry a season's supply, another point for the driver. These joints are made in all sizes for shaft diameters from 3-8 inch up to 1 1-2 inch, advancing by eighths, and on up to 4 inches and more, all sizes above 2 inches, however, being made to order only. The cut, part of which is in section, shows the interior construction of the joint. The space for the grease packing is particularly noticeable, as is also the method of fitting the joint together, and the retaining ring which holds it.



MUTUAL SIMPLE UNIVERSAL JOINT.

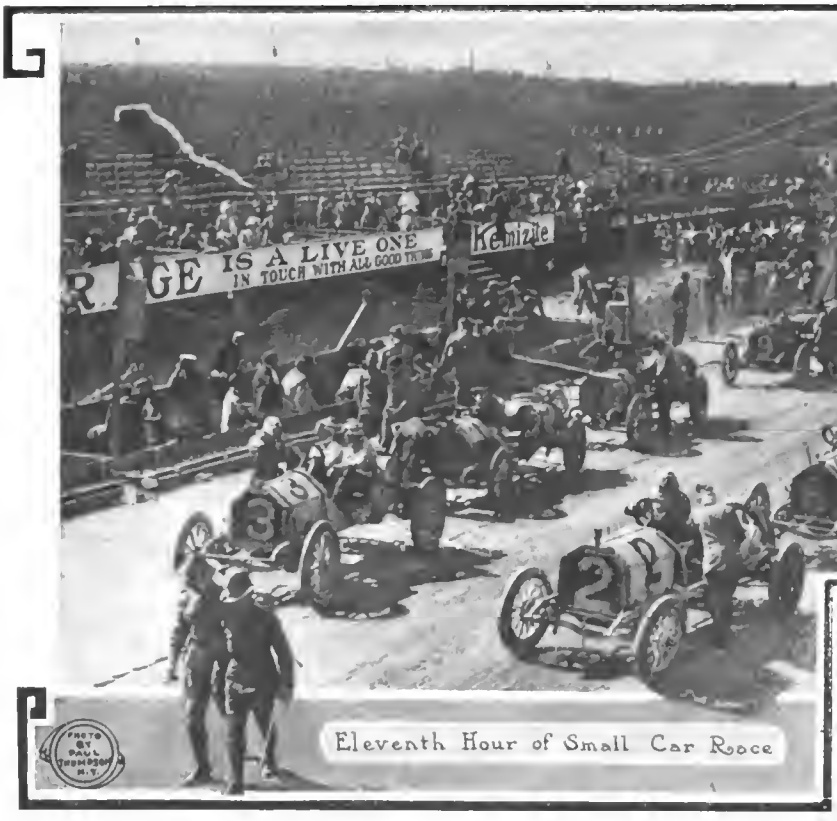
THE AUTOMOBILE

LITTLE CARS SHOW MORE SPEED THAN BIG ONES IN WESTERN STOCK CHASSIS RACES

COBE CUP: LOUIS CHEVROLET, 30.4 H.P. BUICK, 49.3 M.P.H.
INDIANA TROPHY: MATSON, 25.6 H.P. CHALMERS-DETROIT, 51.5 M.P.H.



Eleventh Hour of Small Car Roace

CROWN POINT, IND., June 19—Explanations are as varied as interesting as to why the small cars exceeded the big cars in speed ability in the "Western Stock Chassis Races." Friday, Matson with a 25.6-horsepower Chalmers-Detroit scored best among the small car contingent, which was asked to make ten

circuits of the 23.27-mile course, a total of 232.74 miles. The winner's average was 51.5 miles per hour.

To-day, Chevrolet successfully piloted a 30.4-horsepower Buick, with rare skill and persevcrance, in the big car event wherein the contestants were required to travel 17 circuits, which gave a mileage of 395.65. But the greater distance killed off many, and the victor's sustained flight of speed only footed up 49.3 miles per hour. In the small car race, two besides the winner—Locomobile and Marion—exceeded the speed of the big car performer.

True, it was a bruising distance and the course had a serious handicap in a stretch of over a mile which couldn't be considered other than very bad. A dose of this in every circuit didn't help the cars, especially in the Cobe Cup race, and one after another suffered from disablements which sent them to the side of the road temporarily or permanently.

Mayhap in the effort to give the onlookers a plenteous run for their money, the distance was increased beyond the capacity of the cars for such a course. In like manner, the capacious grand stand offered accommodations for thousands who came not. 'Tis a weakness of Chicago folk to make things bigger than anyone else, and this was their first experience with a great automobile road race.

But let it be said right here, that the job was done prodigiously, and withal most excellently. No expense restrictions interfered with the work of the indefatigable committee, and its members labored from early until late, in order to have everything right up to the mark.

That poor stretch in the course had to be accepted as one of the regrettable handicaps, and if the enormous stand didn't hold the expected throng, it meant that the interest in automobile racing had been overestimated in the West. Even if the events had been "National" instead of "Western," it is a safe assertion that the crowds would not have been any larger, for it must be remembered that the West is always loyal to anything which is branded as of the West.

Credit in huge hunks belongs to that committee which contains the names of Trego, Beecroft, Van Sicklen, Edwards, Sinsabaugh, Ayers, Root and Wheeler. And here, too, should be mentioned the many who helped the grand scheme in minor capacities. The Chicago Automobile Club has good cause to feel proud of its "Western Stock Chassis Races," and to Ira M. Cobe, president, a special vote of thanks is forthcoming.

One of the hitherto unaccomplished things in connection with the racing on the Crown Point circuit was the presence of Illinois State troops guarding an event in Indiana. In the East anything of this sort would have been denounced as "unconstitutional" and impossible. The fact that the races supplied the greater competitive spectacle of modern times free of charge to thousands, wouldn't have had the slightest bearing in the premises. The matter in which the West brushes aside precedent and takes the initiative is invariably most refreshing. It frequently is made to appear that the laws are for the people who have the red blood to insist that their interpretation shall mean the greatest good to the greatest number.

PRESIDENT COBE ON FUTURE RACES

Before the big race for the Cobe cup had concluded there was some talk of next year, and in the course of an interview President Cobe said:

"We do not know whether we want to attempt another race on this scale next year. Perhaps the West does not care enough for such an exhibition. Possibly it is new and we must first show them that the show is worth while.

"I do not think the club will lose $25,000 by the two races. We will not know the cost for two weeks at least. It will be a considerable loss.

"I am inclined to believe that those most benefited by such an event as a big road race should assist appreciably in paying the cost of running it."

MATSON TELLS HOW HE WON

"The only man I was afraid of was Strang," said Matson. "I made up my mind to catch up with him if I could and cling to him all the way around. I did not know that he was disabled on the third lap, but thought he was ahead of me all the time. I knew I had the speed in my car and that my principal task was to hold the light machine together by conservative driving. The race was the fairest that I ever saw.

"None sought unfair advantage of another. During the race I passed every car but the Marion, driven by Monson, and entered as No. 6. Robertson in his Locomobile and I passed each other repeatedly, and he tried to out-maneuver me.

"On the long west stretch of the course I blew out a tire, but Vaughan and I replaced it in one minute and fifty seconds.

"My car responded instantly to the levers, and the way it gripped the road made it hard on the rear tires. In addition to the one I wore out, the one on the other rear wheel wore clear through to the fabric. I knew it was in danger of going and that a stop to put on a new one might lose me the race. As we pulled into Lowell on each lap we knew exactly how far we were ahead. The Chalmers-Detroit camp had a big bulletin board there and gave us the time on each lap. In addition to the time lost changing the tire, we lost one minute and fifty-eight seconds shipping gasoline and water.

"On the last lap I knew that we were more than eight minutes ahead and had plenty of time. So I kept a steady pace and took no chances. It was on this lap that Robertson tried to jockey me out of the race. He knew my tire was bad and he passed me and fell back to tease me into sprinting ahead of him. This I would not do, but let him have third place, not to risk unnecessarily the race I already had won."

CHEVROLET'S OPINION OF THE BIG RACE

After the race was over, and the excitement had subsided enough to permit of actual thought, Louis Chevrolet had the following to say about his victory: "I drove the last eight laps of the race on nerve—nothing else. When I lost the use of one cylinder as the result of the hard jumping over the rocks I almost wanted to give up. But something told me to stay in. It must have been the training I received while a mechanic for Hemery, the greatest motor racing driver the world has ever known. He never has been known to give up. He taught me to drive that way in all my contests.

"It was a hard drive, though. I weighed myself Friday when the officials were inspecting the cars, and honestly, I'm twelve pounds lighter to-night than I was before the start. Two such contests in rapid succession will tell on any man. I wanted to hang up a road record, but the course was in dangerous shape. I can only say I am indeed happy, for hard luck followed my partners, Strang and Burman, all through the two races here."

Ante-Race Stories Scared Away the Crowds—Accounts of the great crowd that was expected, the high prices that would be charged for food and shelter, and the probability that visitors might go hungry, are thought to have kept many from the scene of action. There were vivid tales of how automobile-race goers might have to fight for something to eat and how they would be jostled about, so that officials have concluded that many stayed at home for that very reason. After it was all over, it was realized that the prices were no higher than might be expected, perhaps double, the charge for a 25 cent meal being 50 cents. There was no great dearth of food, and the crowd was not in an "ugly" mood, as some perhaps had feared. Coffee retailed for five or 10 cents a cup, depending upon how the purchaser asked for it and the appearance of the asker. Under cover the charge was a dime, but on the streets the same liquid was a nickel. Sleeping quarters were seldom, if ever, sold at more than $3 a room, and those at $10 were the unfortunate dreams of over-zealous press agents.

Chevrolet, the Winner, and Nelson, the Mechanic Who Helped

CROWN POINT, IND., June 19—Chevrolet in his contest for the Cobe trophy had to contend against four successive adversaries who confronted him at one time or another during the seventeen laps of the big race. Of these four (Burman, Denison, Robertson and Bourque) two (Burman and Denison) fell by the wayside before the race was one-third over, but the other two (Bourque and Robertson) contended to the finish. In the first two laps his team-mate Burman was his rival, Burman leading Chevrolet five seconds in the first lap, and fifteen seconds in the second. At this juncture, Denison with his Knox came to the fore, and not only took the lead away from Burman but placed himself also 42 seconds in advance of Chevrolet. In lap three Denison piloted the Knox around the circuit in 22:34, establishing the time record for the course. Lap four found Chevrolet to the front for the first time, having the advantage of but 12 seconds over Denison and 57 seconds over Burman. But his lead was short lived, as Denison, who had tire troubles, was destined to put the Knox to the front on the fifth lap in what proved to be the second fastest of the day, 23:08. Denison relinquished his hold, however, in lap six, due to tire troubles, he having to stop 2 minutes 10 seconds at the end of this lap to take on a tire and oil, and having lost more time during the lap changing a tire. This permitted Chevrolet to lead at the end of lap six with a margin of 2 minutes 22 seconds. Burman retired during this lap owing to gasoline troubles and went out of the race. No sooner had he ceased as a factor than both Robertson in his No. 9 Locomobile and Bourque in the No. 2 Knox entered into the first place conflict. Chevrolet had a lead of almost four minutes on Robertson and five minutes on Bourque, in the seventh lap, at which time Denison had gone out of the race owing to a breaking of a connecting rod. Denison stated previous to the start of the contest that his engine had been run for almost two years without the cylinders being taken off, and he had asked for a new engine before the start of the race.

With the fight in lap eight a three-cornered one involving Chevrolet, Robertson, and Bourque, the Frenchman gained an advantage on the seventh lap and finished 6 minutes 30 seconds to the good in the eighth. He was now leading Bourque's Knox by over 18 minutes, Bourque having stopped 7½ minutes in this lap at the grand stand to change tires and take on gasoline, oil, and water. But Chevrolet's pace was being rapidly eaten into by Bourque and Robertson. In lap nine Robertson cut the lead practically 2 minutes and Bourque lost but 6 seconds to Chevrolet.

It remained for lap ten to be Chevrolet's Waterloo, he requiring 44 minutes 1 second to make the circuit, while Robertson romped around in 24:57 and Knox in 27:17. This was the lap when Chevrolet had valve troubles. At the grand stand at the completion of the lap he changed two rear tires, took on gasoline, and some extra valves. The delay allowed Robertson to take the lead at the end of lap ten by a clear margin of 12 minutes 32 seconds. Bourque at this time was only 1 minute 15 seconds behind Chevrolet. Lap eleven saw Robertson leading Chevrolet by 27 minutes 7 seconds, and Bourque leading him by the narrow margin of an even 10 minutes.

In lap twelve this order of Robertson-Bourque-Chevrolet remained, Robertson having dropped his lead to 19 minutes 14 seconds owing to a stop at Lowell. At the end of this lap he stopped at the grand stand for 4 minutes 40 seconds to take on supplies and change rear tires. This delay accounts for his losing 6 minutes to the Frenchman.

If lap ten was Chevrolet's hoodoo, lap thirteen proved the undoing of both Robertson and Bourque. Robertson had a 6 minutes stop during the lap at Lowell because of ignition troubles, and when he reached the grand stand at the completion of this lap 13 minutes were needed to change the magneto and do some other adjusting. Part of this proved fruitless, as a test of the magneto immediately after it was off showed it was in perfect working condition. While Robertson was working over his difficulties, Bourque was aware of his. During this lap Bourque had filled with water and failed to close the petcock at the base of the radiator, so that when he reached the grandstand not a drop of water remained in the radiator or jackets. It was taking too great a chance to pour cold water into the jackets, and by

Chevrolet (Buick) Took Corners Skillfully But Cautiously

Bourque (Knox) Once Appeared a Certain Winner, and Supplied the Gamest Kind of Fight to Finish

actual stopwatch he consumed 12 minutes 40 seconds for gasoline, water, and oil and getting started. These extraordinary delays proved the undoing of Robertson, who dropped from first place to third, and Bourque took the lead by slightly over a 6 minute margin from Chevrolet.

Chevrolet, starting with lap fourteen, had settled down in the run for the finish, having enough tires and sufficient gasoline and oil to carry him over the finishing line. He held the lead throughout the remaining four laps, although Bourque was gradually reducing it. In lap fourteen he led Bourque's Knox by 2 minutes 54 seconds. In the fifteenth lap Bourque cut 40 seconds off of this. In the sixteenth lap he reduced it 53 seconds more, and in the seventeenth lap he cut 16 seconds off. But it was not sufficient to win, as it left the Frenchman a final margin of 1 minute 5 seconds, with Robertson 12 minutes in the rear.

While Chevrolet, Bourque, and Robertson were fighting out the first positions, an interesting struggle was taking place between Hearne in No. 11 Fiat and Englebeck in No. 5 Stoddard-Dayton, the former finally winning out.

Although the real struggle was among the five cars that actually finished the contest, there were other factors in the race that kept matters at fever heat until they dropped out. Chief among these was Miller's No. 1 Stoddard-Dayton, which was a strong factor up to the fourteenth lap, when it was eliminated by shearing four pins in the universal joint in the propeller shaft. The report was circulated that the car was in a ditch with two rear wheels off, which proved false, as Miller brought the car to the grandstand before the finish of the race, having taken two pins out of the other universal joint to repair the broken one. His third lap was one of the fast laps of the day, being made in 24:11.

Strang, who was looked to as a possibility, never proved dangerous. In lap one he stopped to take on a supply of valve pins which had been giving trouble, and in lap five was stopped for 1 hour 10 minutes in front of the grandstand while the mechanic effected some valve repairs. After this he made attempts at the lap record, but failing to get closer than 1:23 seconds of the mark set by Denison's Knox in lap three.

First Lap—Following their tactics in the Indiana trophy race, the Buickers again started to burn up the road in the Cobe cup and the result again showed that the Buicks had made the best time for the initial lap, Burman, last to start, having negotiated the circuit in 24:15, which was 34 seconds slower than Burman himself had done in the curtain-raiser. The first one past the grand stand in this lap was Bourque in the Knox, who had caught and passed Miller in the Stoddard on the west leg. Chevrolet, even thus early showed he was not to be overlooked, for in point of time he was second to his team mate. Bourque was in third place, while Denison was just warming up in fourth. Seymour was the first to experience trouble on this lap. At the very first turn he slapped on his brakes, which, however, were covered with oil. So terrific was the pace at which Seymour was going that he skidded completely around on the road and tore off two tires. Finishing this lap, Strang was the first to go to the pits, a pin on a rocker arm having been lost. Burman's pace may well be imagined when it is known that he was timed over the special mile stretch at 87.6 miles per hour.

Second Lap—Bourque still continued to hold his place at the head of the procession, finishing the second lap, although he was not the actual leader. Burman still had that honor, his second lap being even faster than his first. Chevrolet, too, was putting up a good battle against Father Time and was runner-up. While the racers were going on this lap the report came that Florida was out of the race without even finishing one round, a sleeve on a camshaft breaking and ending his career just after turning into the home stretch. Denison was becoming a factor even thus early, and the running of the Knox made it a favorite.

Third Lap—This round furnished a big sensation and made Denison and the Knox even greater favorites, for the time showed a record had been broken, Denison having negotiated the circuit in 22:34, the fastest time ever recorded for the circuit and equal to 62 miles an hour. This terrific pace carried him to the front. Burman had slipped back to third and his team mate, Chevrolet, still hung to second place, being 42 seconds back of Denison. Bourque in the other Knox hung onto the lead and was in fourth place, while Robertson was "jogging along" fifth. There was only 3 minutes 21 seconds between first and fourth, so it was becoming a real race.

Fourth Lap—Denison slowed a bit the fourth round, while Chevrolet, continuing his even pace, went to the front, having the lead by 12 seconds. Burman was holding third, while

Robertson (Locomobile) Rounding Cemetery Turn Without Any Apparent Thought of the Hereafter

Bourque was fourth. Seymour had enough on this round, a broken connecting rod stopping him near Cedar Lake. It seemed at this stage as if the contestants had settled down to a steady grind, realizing that a 400-mile race was far from being a sprint.

Fifth Lap—Denison got his second wind in this round. He went out after Chevrolet and got him, his round in 23:08 being the second fastest on record. Chevrolet was only 5 seconds slower than on his fourth round, but Denison picked up enough to make him the leader of the race by 1 minute and 19 seconds. The way he was going it looked as if he would maintain the lead to the end. Still, the first five were remarkably close, there being only some 3 minutes separating first and fifth. Hearne in the Fiat was plugging along consistently, evidently having laid out a schedule and being determined to hold to it.

Sixth Lap—Chevrolet came into his own on this lap, closing up on Denison and being better than 2 minutes to the good of the Easterner who had again slowed after a fast round. Chevrolet had done his lap in 25:47, his slowest so far, while Denison had dropped back to 29:28. Burman had engine trouble and quit after having been in third place; this, of course, moved Bourque up a peg. Robertson in the Loco was holding his own, while Hearne was showing regularity and precision of running.

Seventh Lap—Denison went down and out on this round, a connecting rod breaking and the front end of his car catching fire. This removed a most formidable rival from Chevrolet's path and he was glad of it, for his pace was slowing as was that of the others. Robertson profited and climbed to second, becoming at once a favorite with the people, who declared the Vanderbilt winner was just about to make his run to the front. It looked that way at least, although on this round Chevrolet had the fastest time. Robertson was more than 4 minutes back of the flying French leader.

Eighth Lap—The Frenchman again clipped off the fastest lap in this round, doing 25:50, while Robertson slowed, although holding second place. Bourque was still third, while Miller was fourth. Englebeck was holding fifth, with Hearne sixth. Lytle, in seventh place, was having trouble with his magneto and a broken spring, but still was on the move.

Ninth Lap—Again it was Chevrolet who held the time honors when this round was completed and it was with Robertson grimly hanging on. At this stage the Locomobile driver gave evidence that he was not to be overlooked and that he was far from being beaten. His was the fastest round, the watches giving him 25:38. Chevrolet had dropped to 27:14, his slowest of the race, and there was a difference of but 5 minutes between the two. Bourque hung to third and in fourth place was Miller in the No. 1 Stoddard, who was just ahead of his running mate, Englebeck. Hearne was sixth and the last man with a chance to win.

Tenth Lap—This round nearly saw the end of Chevrolet, for it was on this lap that he had his engine trouble, a valve breaking and getting into a cylinder and punching a hole in the piston. But the Frenchman was not discouraged. He patched it up as best he could and continued on three cylinders. This gave Robertson his chance and the Locomobile shot to the front by virtue of a lap in 26:35 to 44:01 for Chevrolet, and led by 13 minutes and better. Bourque was still third and Miller fourth.

Eleventh Lap—Lytle withdrew at this stage of the race, leaving only seven cars, of which number the Strang-Buick was practically out. Robertson continued making his fight for the cup and it began to look very dubious for Chevrolet. Robertson cut out 24:57, it being the third consecutive time he had made the fastest round, and he had Chevrolet by 16 minutes. It seemed all over but the shouting, but Chevrolet limped along grimly on those three cylinders, determined to finished at any rate. His trouble had relegated him to third and Bourque found himself in the position of runner-up. Miller was fourth and Hearne fifth.

Twelfth Lap—Robertson began to have trouble at this stage of the race. He was held up 6 minutes at Lowell and while he was first when the tape was crossed his lap was a slow one—36:20. Still, he was 20 minutes ahead of Chevrolet, who had dropped to third place, while Bourque had gone to second. All the cars were slow on this lap, the 26:13 of Bourque being easily the fastest.

Thirteenth Lap—A new leader developed this time around, Bourque going to the front for the first time in the race. He had an advantage of 7 minutes over Chevrolet, both of them having caught and passed Robertson. The Locomobile man thought his magneto was giving trouble and he released his grip on the

lead when he stopped in front of the stand to change for a new one. It is said, however, that it simply was a case of a loose igniter and that Robertson could have stuck in front if he had tightened that instead of using up his lead changing magnetos.

Fourteenth Lap—Bourque did not hold the lead long. He had to stop at the pits in this round and while he was working on his car, Chevrolet again came into his own with 3 minutes' lead over the Knox. Robertson was again running good and in third position, while Englebeck was fourth and Hearne fifth.

Fifteenth Lap—It was getting interesting at this stage of the proceedings. Bourque was fighting to again catch Chevrolet and the Buicker was struggling to keep in front. Hearne made the best time on the lap and was getting up nearer to the leaders, but Chevrolet was still in front. Bourque picked up nearly a minute on his rival and it looked like a close finish.

Sixteenth Lap—Chevrolet, Bourque, Robertson and Englebeck was the order beginning the last lap. Chevrolet had 1 minute 21 seconds advantage over Bourque, while Robertson was so far back that he was not regarded as a factor. To win he would have had to beat Chevrolet more than 13 minutes on the lap, and that looked impossible. So Bourque was the only one with a chance and the crowd got up on its toes to watch the fight which only ended at the finish.

Seventeenth and Final Lap—Bourque was the first to finish the race, dashing across the tape at a good clip. Then came a wait for Chevrolet and as the watches ticked off the seconds it looked like a Knox victory. Finally, however, the trumpets sounded and at the top of the second hill there appeared a car. It was coming fast and as it shot under the bridge at the south end of the stand, and across the finish line, the people recognized Chevrolet. Even then they were not sure he was the victor and few cheers were heard as he crossed the tape. The people waited breathlessly for the verdict of the timers. Finally it came, showing that the Buick had won the Cobe Cup by the narrow margin of 1 minute 5 seconds, having averaged 49.3 miles per hour to the 49.2 of Bourque in the Knox. Robertson came third at 48, Hearne in the Fiat fourth in 47.2 and Englebeck fifth in 46.9. The unlucky Strang still was running when the race was called off.

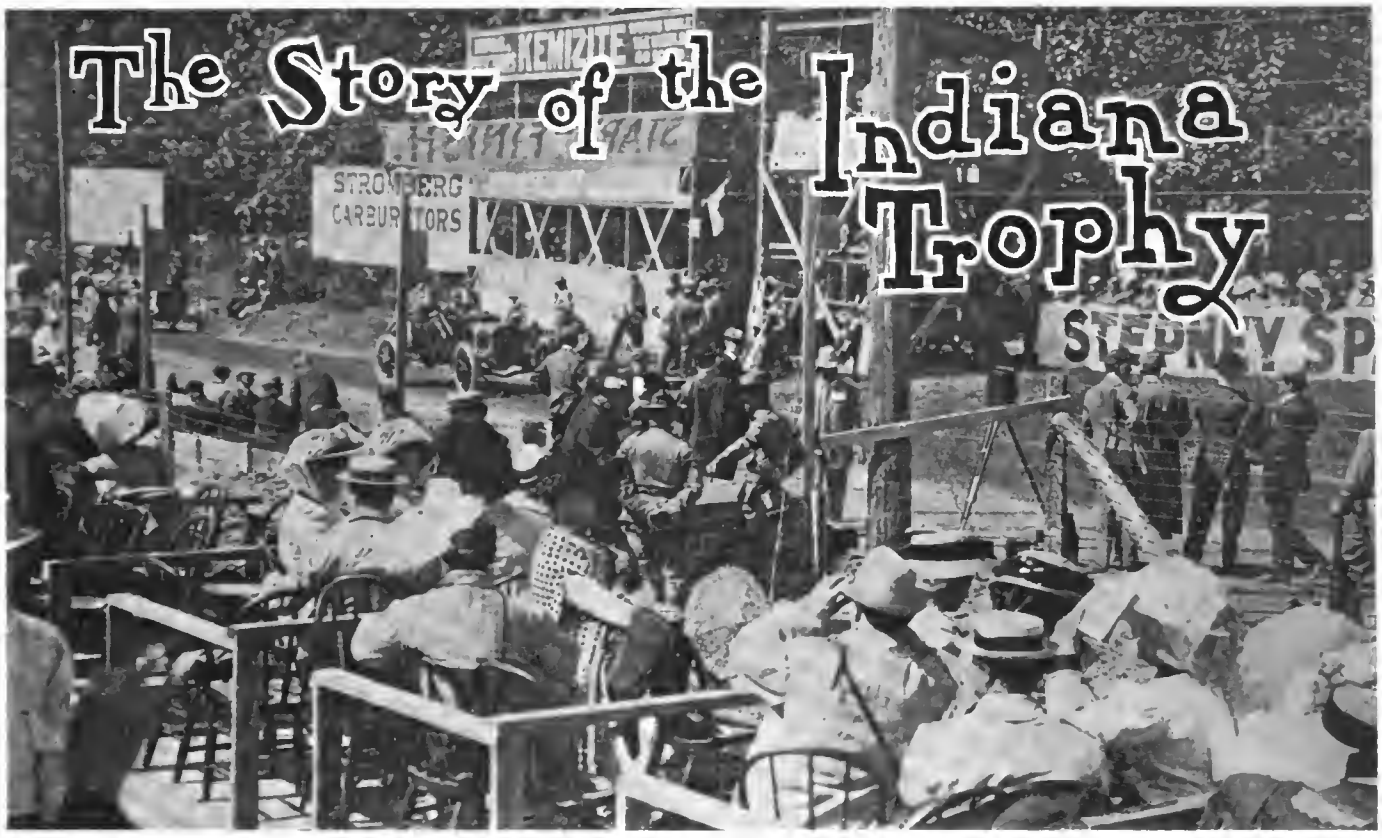
Note—A number of facts not brought out by the four tables given on this page and the one on the opposite page are of interest. Thus, Denison, who had such hard luck, after making a determined bid for the lead, not only heads the list of fast laps, but made the second best also. This was on the fifth lap, when rising from second to first position, he did 23:08. Following this a slow one in 29:28 put him back into second place. The remarkable regularity of running of the two Locomobiles in the Indiana did not have any counterpart in the Cobe. In the former race, no one of Robertson's first five laps varied more than ten seconds from 28 minutes for the circuit. At the same time, Florida was reeling them off close to 29:30, no one of his first seven being farther away from that mark than 30 seconds.

Lytle Taking His Apperson Around Graveyard Turn

The Story of the Indiana Trophy



Small Cars Lining Up for the Indiana Trophy Event on the First Day

CROWN POINT, IND., June 18—That the 232.74-mile road race held to-day for the Indiana trophy will go down in history as one of the greatest small-car races in America is beyond doubt. Of the sixteen starters, nine were running at the finish, and six completed the ten laps, thereby setting the record for the greatest number of finishers in any American road race. The cars were all tuned to the minute, which is borne out by the consistent running of many of them. The winning Chalmers team had been on the course early, and the little cars had been doing consistent work in the daily practicing. A surprising feature of the race was the speed the little cars made and the reliability they showed. After the first two or three laps, many predicted they would soon stop, but these "Doubting Thomases" were more surprised to find them running with the same regularity at the end of the 232 miles. The speed of Matson's winning Chalmers was greater than had been anticipated, and, as after events proved, it maintained a higher average for its ten laps than did the winner of the Cobe trophy for the seventeen laps of the following day.

According to his own words, Joseph Matson, driver of No. 19, winning Chalmers-Detroit, was not certain as to his status in the race until the fifth lap, when he had sufficient lead to give reasonable assurance of winning with consistent running. Matson started out slowly, requiring 29 seconds for the first lap, which put him in eleventh place, Strang and Burman, in Buicks, setting the fastest times. Strang was eliminated in lap two by breaking an axle, and Matson, by driving the lap in 25:43, was able to climb from eleventh to third place, leaving Burman in first place with 5 minutes' margin, and Poole, his running mate, in another Chalmers, 67 seconds ahead of him.

Lap three was the one that gave first evidence of Matson's work, and when he finished this lap and had landed in first place, overtaking ten competitors in two laps, it was good evidence of what might be expected at the finish. As it was, he got the lead and held it tenaciously to the end with the exception of lap four, when Knipper, his running mate, wrested it from him by 2 seconds. Unfortunately Knipper cracked a cylinder in the fifth lap and the promised fight between Matson and himself vanished.

Laps three and four were essentially Chalmers-Detroit laps in that Matson, Poole, and Knipper, driving the Chalmers team, were the three leaders. In lap three the times were: Matson, 1:20:24; Poole, 1:20:28; Knipper, 1:20:47. But 25 seconds separated the three, and in lap four this triangular home fight continued, with Knipper, 1:46:27; Matson, 1:46:29, and Poole, 1:46:54.

In lap three Chevrolet, Robertson, Wells in a Moon, and Wiseman in a Stoddard-Dayton, were trailing the Chalmers trio closely, but in lap four, Chevrolet was out because of valve troubles, leaving Monsen in the Marion, Robertson in the Locomobile, and Wells in the Moon, close rivals. Lap five saw Matson back in first position, his running mate, Poole, two minutes later, a five-minute margin separating Monsen in third place, and a seven-minutes safety gap between him and the Locomobile. This was the first period in the race when the leader had a minute or more leeway, and gave him an opportunity to plan a complete run. This order of Matson leading with Monsen-Marion and Robertson's Locomobile in close pursuit continued through laps seven, eight and nine, and in the final lap Robertson moved up into second place, leaving Monsen in third.

While the struggle among these three for three first positions was engrossing attention, an interesting contest was taking place among Florida's Locomobile, Wells in the Moon, and Wiseman driving a Stoddard-Dayton. In lap seven Wiseman's time was 204 minutes 3 seconds, Wells' time 204 minutes 26 seconds, and Florida's 205 minutes 22 seconds. Lap eight saw Wells take the lead of the trio with Florida next, and Wiseman third. In lap nine Florida had taken what proved to be fourth honors away from the Moon, which was running but 43 seconds behind it, and the Stoddard was nearly a minute later. This order changed in the final lap, Florida still holding to fourth position, but Wiseman moving the Stoddard up into fifth, and the Moon finishing in sixth scarcely 3 minutes later.

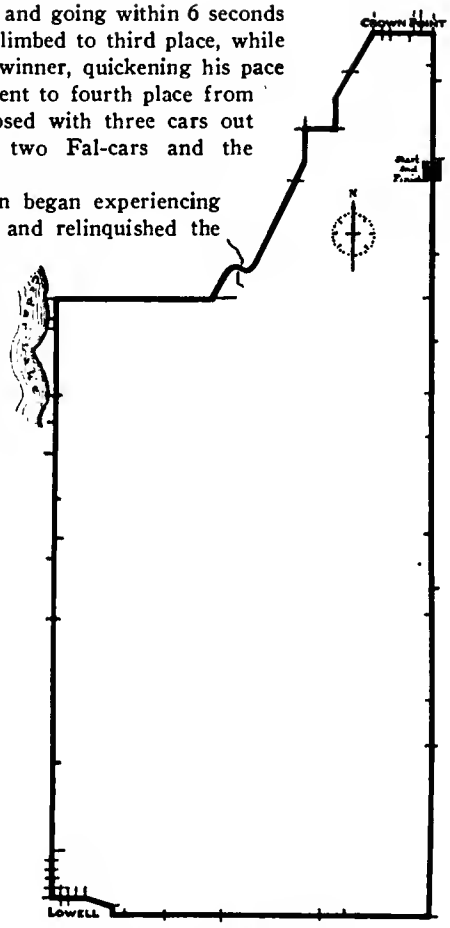
Viewed from the grand stand, the race was entirely bereft of pit incidents, not a single car having to change tires at the pit during the run. Wiseman in the Stoddard-Dayton stopped in the third lap to take on oil, requiring exactly 1 minute and 25 seconds. Robertson halted his Locomobile exactly 50 seconds in the

fifth lap to replenish with oil and gasoline, and in this lap the Moon, No. 11, took on oil. A bad leak in the oil tank was discovered and 3 minutes and 45 seconds consumed in filling the tank and trying to repair the leak. Matson made four stops during the run. In lap one, he changed a tire due to a blow-out about 5 miles from the start. In lap four another blow-out occurred, and in lap seven he stopped at the grand stand for gasoline and oil.

First Lap—Evidently the Buick team had received instructions to "beat it" from the start, for both Burman and Strang wasted no time in getting under way, Burman, in particular, clipping out a pace for the first lap that was faster than anything that had been shown in practice by the little cars. He soon caught Maisonville in the Corbin, who had started first. This left Burman out in front and the Buicker improved the opportunity afforded by the clear course to whiz around the circuit in 23:41. Strang, his team mate, showed 24:32 2-5, having caught Robertson and crossing the tape with Pearce in the Fal-car. Even at this early stage, though, the Chalmers-Detroit got into the running and it was Knipper in No. 5 who was third in point of time, his lap figures being 25:55. Maisonville was in fourth place and Pearce in the Fal-car fifth. The only absentee on this circuit was Ruehl in the Fal-car, who, however, managed to make the lap several hours later, crossing the tape for the first and only time after seven laps of the race had been run. It was apparent that the ones who later became the most important factors in the fight for the trophy were in no hurry at the start, for Matson was tenth in point of time, his first lap being his slowest. Robertson, too, "jogged" around the first time, being eighth, while Monsen was just ahead of him.

Second Lap—This terrific pace began to tell in the second round. Strang and Burman continued their helter-skelter clip and the former got his quietus at the cemetery turn at Lowell, where he stripped a pinion on his rear axle and took the count. Burman, however, managed to hold the lead he had gained in the first lap, but his time for the second circuit was considerably slower by nearly 3 minutes. With Strang eliminated, Wiseman in the Stoddard became second. His two laps were remarkably consistent, the first being 27:58 and the second 27:36. Poole, running evenly and going within 6 seconds of his first lap time, climbed to third place, while Matson, the ultimate winner, quickening his pace by some 4 minutes, went to fourth place from tenth. The round closed with three cars out of the running—the two Fal-cars and the Strang Buick.

Third Lap—Burman began experiencing trouble in this round and relinquished the lead he had gained the first two laps. He sifted back in the rapidly moving field and was ninth when he crossed the tape. At this stage the Chalmers colors came to the front and the finish of the lap saw all three Bluebirds flying out in front, Matson leading, with Poole second, and Knipper third. Chevrolet showed his first and only flash on this lap when he worked up into fourth place, nearly a minute back of Knipper. The race had settled down to a grind and the sprinters evidently had given up all idea of running the legs off the others. The Chalmers drivers were running on a well-arranged schedule and it looked even at this stage as if they



Map of the Course

Matson and His Chalmers-Detroit "Bluebird" Rounding the Much-Talked-of "8" Turn

Designer Riker, Driver Robertson, and the Big Locomobile

Monsen and the Consistent Marion, Which Finished Third

were going to have a lot to say at the end of the race. The three Bluebirds were identical in appearance, and judging by the manner in which they were running, predictions were made that two of them would be in the first three.

Fourth Lap—Billy Knipper showed his nose in front in the fourth lap when he came up from third place and assumed the lead. His mates, Matson and Poole, were right with him, though, there being only 27 seconds separating the first and third Chalmers, showing remarkable consistency of running and a well-arranged schedule. On this lap Chevrolet had enough and retired from the contest, leaving an even dozen cars still running. It was engine trouble in his case. Monsen in the Marion had crept up a place through the retirement of Chevrolet, while Robertson in the Locomobile and Wells in the Moon were traveling well. The whole field was well bunched at this stage of the proceedings, all of the first six cars being inside a 6-minute blanket.

Fifth Lap—It was only a temporary eclipse for Matson when Knipper passed him in the fourth lap, for at the finish of the fifth Matson again was clipping out the pace and he never was ousted from the lead from this point on. The Chalmers suffered the loss of one man in this lap when Knipper broke an oiler lead which resulted in his retirement. This jumped Poole into second place, while Monsen in the Marion stuck to the heels of the second Chalmers. This was the half-way point in the race and there was only 5 minutes between first and third. Robertson had been running on a schedule, figuring on 51 miles an hour for the first half, after which he had intended going after those in front of him. He was 7 minutes and 30 seconds behind Matson at the half-way mark and those in the stand concluded that Robertson had his work cut out for him, so well was the Chalmers running. Ten cars were left in the fight at this point, but of these ten, only eight had any kind of a chance. Maisonville in the Corbin and Wright in the Stoddard being so far back they were not given any kind of consideration. Burman dropped in this round, disqualifying himself when he borrowed a valve from Strang's car which he found deserted on the cemetery turn at Lowell. Burman made the change, picked up Strang and drove to the finish, where he ran his car off the course and retired from the race.

Sixth Lap—Poole was sifted back into the rear in this round, dropping from second to eighth. Matson still kept his lead, being closely pursued by Monsen, who was the dark horse of the race. Monsen, however, was 7 minutes back of the leader and was in danger of being caught by Robertson, who at this time began to show an inclination to get to the front. Wells in the Moon had been sticking to Robertson like glue and at this stage it looked to be a fight for second place in which Monsen, Robertson and Wells were the interested parties.

Seventh Lap—Matson still had the speed of the party and his seventh lap was the fastest of the lot; Monsen picked up a bit on those who were chasing him, while Wells closed 15 seconds on Robertson, whose slowest lap of the ten was this one. No one of the drivers quit in this round, there still being ten cars which were in the running.

Eighth Lap—This round saw the elimination of Stutz in the Marion and Wright in the Stoddard. They had been far in the rear anyway and their dropping out did not alter the positions of the leaders. Matson had a slow lap and so did Monsen, but Robertson picked up a couple of valuable minutes, which improved his chances of getting second place. His 27:41 was the fastest of any of those battling for the cup.

Ninth Lap—At this stage of the proceedings Matson appeared like the winner, having an excellent lead. The Chalmers was running very sweetly and holding its own in point of speed with the others. Robertson was getting desperate at this point

Wiseman's Stoddard-Dayton Was One of the Finishers

Wells and the Moon, Which Finished in Sixth Place

HOW THE LEAD SHIFTED DURING THE RACE FOR THE INDIANA TROPHY, JUNE 18, 1909

No.	Car	H.P.	Driver	Mechanic	Tires	1st Lap	2nd Lap	3rd Lap	4th Lap	5th Lap	6th Lap	7th Lap	8th Lap	9th Lap	10th Lap

11	Moon	32.4	Wells	Goetz	Diamond	10	9	8	6	5	4	5	4	5	6
17	Chalmers-Detroit	25.6	Poole	Gereau	Michelin	6	2	2	2	2	8	8	7		
1	Corbin	32.4	Maisonville	Aude	Diamond	4	13	13	12	10	9	9	8		
3	Marion	28.9	Stutz	Tinkler	Michelin	12	10	11	10	8	7	7			
18	Stoddard-Dayton	24	Wright	Bell	Michelin	15	12	12	11	9	10	10			
5	Chalmers-Detroit	25.6	Knipper	Richards	Michelin	3	4	3	3						
2	Buick	30.4	Burman	Grinnon	Michelin	1	1	9	9						
8	Buick	30.4	Chevrolet	Poirier	Michelin	14	6	4							
14	Buick	30.4	Strang	Hart	Michelin	2									
9	Fal-Car	28.9	Pearce	Stanfer	Diamond	5									
15	Fal-Car	28.9	Ruehl	Kutz	Diamond	16									

and he got his signal to "beat it" to the end. He was only 38 seconds behind Monsen and it seemed as if he would be able to overhaul the Marion before the final flag. Florida, too, was in good position, being fourth to his team mate's third, but 10 minutes behind him. He passed Wells, who had had to change spark plugs and dropped back a place.

Tenth and Final Lap—To win the race Robertson had to make up 8 minutes on Matson in one round, which was manifestly impossible the way the Chalmers was running. The only chance Robertson had was to have Matson meet with some mishap and that hardly seemed likely. Therefore Robertson was out to climb to second place and he set out to pass Monsen, who was putting up the gamest kind of a fight for the honor of being runner-up. But Robertson did not spare his car and he clipped off 27:40 4-5. Matson made a strong finish and did 26:59. On the other hand, Monsen ran his slowest lap of the ten, it requiring 30:49 for him to make the circuit just when even seconds were precious. This slow lap sent him to third. Florida held fourth place, into which he had climbed in the previous round, and the only shift in position of the others was the passing of Wells in the Moon by Wiseman in the Stoddard. This left the final positions: Matson, Chalmers, average 51.4 miles per hour; Robertson, Locomobile, average 50 miles per hour; Monsen, Marion, 49.5 miles per hour; Florida, Locomobile, and Wiseman, Stoddard, 47.4 miles per hour, only 14 seconds separating them, and Wells, Moon, 46.9 miles per hour. At the end Poole in the Chalmers and Maisonville in the Corbin still were running, although hopelessly out of the fight.

AVERAGE SPEED OF LEADERS IN INDIANA TROPHY

THE GOSSIP OF THE STOCK CHASSIS RACES

Hard Luck of the Corbin—First of the cars to start in the Indiana Trophy race was the Corbin, driven by Maisonville, who had good reason to bemoan the fate that put him out of the running on the first day. There was considerable difficulty in getting the soldiers placed around the course, so much so that the start of the race was delayed for an hour. Supposedly by that time the truckloads of militia had been entirely distributed, but despite the red-flag signal which greeted the Corbin as it came up a rise in the second lap a heavy truck occupied the center of the road on the down grade following. It was a case of slap on the brakes, which burned out very quickly and settled all chances of the Corbin participating in the real battle, although Maisonville got going again and was running lap after lap well under 30 minutes when the race terminated.

Some Grand Stands Were Out of Sight and Empty—Nearly a hundred grand stands of varying sizes and pretensions had been built by farmers and others around the course in order to secure some of the fabulous wealth supposed to be expended at automobile races, if reports from the East were to be believed.

Dennisen (Knox) Who Made Record Lap of Course

Maisonville (Corbin) Who Failed Through No Fault of Car

The inhabitants of the district who had built soon began to figure losses, for most of the seats went begging and those who did pay for a "stand-seat" had plenty of room. Even the big stand erected to hold 10,000 persons, at $5 each for the two days, right at the finish, was not half filled on either day, and the parking spaces across the way had two banks of cars—in a few spots. The idea of those in charge that $15 and $10 spaces would be in demand was sadly blasted. Lumber was cheap on the day after the tourney.

Lytle Said Course Was Worse Than Briarcliff—After he had given up the struggle because of rear springs broken in the stretch of soft gravel road and backed his Apperson in behind the press stand, "Herb" Lytle said:

"The course is in awful shape for a short stretch. If I could have saved the machine in any sort of shape I would have kept running on three springs. The Briarcliff course was bad, but the one spot in this is worse. All the cars are slowing up over it as they strike their running gear, so badly is the road cut up. Other parts of the road are fine. This bad spot must be built over if the race is to be run again."

The bad spot was a mile long in the stretch leading to the finish, about five miles from the tape.

"Wag" Delighted the Westerners—Fred J. Wagner, the starter of the really big races, was once an inhabitant of the Windy City, but the races on the Crown Point course were the first of their kind in that section of the country, and consequently the first which he started there. So all the papers and many in the crowd were awed and pleased with his "Ten, nine, eight, . . . three two GO." It sounded realistic, and gave the crowds the feeling of hearing something of which they had previously read. So "Wag" was an extraordinarily noted personage, and all the youngsters in Crown Point are making raids on the clothing stores for checked short pants, leather puttees, and German caps with leather visors.

Michelinites Were Happy—Among the naturally interested onlookers were: M. Hauvette-Michelin, who is the executive head of the American factory of the Michelin Tire Company at Milltown, N. J.; Manager "Jack" Matlack and Advertising Manager Bramwell. With such a preponderance of cars equipped with Michelins the Milltowners were inclined to feel quite confident, though they could not resist the enthusiasm which naturally followed in the wake of the victory. M. Hauvette-Michelin has seen all of the principal European races, but his first American experience was at Savannah and the second at Chicago.

Indiana Trophy Presented to Matson—Clothed and in their right minds, Joe Matson and Mechanic Dan Vaughn were recipients of the Indiana trophy and a great ovation just before the start of the big car event. The winner of the light car race came to the stand in the victorious Chalmers-Detroit, President Ira M. Cobe of the Chicago Automobile Club presenting the handsome silver cup to Matson. The appearance of the crew was far different from their looks when they completed their work on the previous day, for straw hats and light spring suits had replaced the oily sweaters and jerseys of the racing togs.

The Commercial Hotel at Crown Point, Ind.—With race headquarters at Crown Point, the Commercial Hotel, of which Mrs. Beers is the hustling manager, assumed some importance in the matter of providing food and lodging for the thousands. One inconsiderate boarder found fault with a towel which had done much service in the public washroom and registered a kick with Mrs. Beers, who came back with the emphatic remark that "Over forty men have used that towel and you are the first one to kick." There was no clean towel forthcoming!

Harry Knight the Dean of the Timers—From Boston came the man who took charge of the timing of the cars in their flights. Harry Knight is a well-known figure in New England automobiling, and he has extended his timing operations to various parts of the country. With his trusty chronometer and array of stop-watches, Knight saw that the timing of the autos was made accurately and without friction. "Demountable" Nadall lent a good hand in the job.

Arrangements Were Wonderfully Good—Perfection in management and preparations were everywhere evident, sub-

The Cobe-Myers Grandstand Box

Includes the Locomobile Box Party

stantiating the fact that what the people of the West do is generally done well. Miles of woven wire fencing had been erected to keep back the crowds, 23 miles of asphalt road had been laid, the press stand was a joy to the busy newspaper men, the telegraph wires, telephone lines, and viaducts were well placed, and the soldiers were real.

Matson a Former Cyclist with "Dutch" Waller—There were those at the race who did not recognize in Matson, the winner, an old-time bicycle rider, an honor which carries a bond of unity with it, among those who graduated from bicycles to automobiles, and are now looking forward to aeroplanes. Matson was once the racing partner of "Dutch" Waller, who was well known in the six-day events, and later as the engineer of a motorcycle.

How a Broadwayite Got Stung—"Sid" Bowman was among the "Broadwayites" who fell victims to the wiles of the local Hoosiers, who naturally were after money when such easy picking abounded. "Sid" boarded a 'bus bound for the grandstand, paid his way upon demand after only a small fraction of the distance had been traversed and then was dumped out a mile from the destination point.

The Locomobile Party—One of the grand-stand boxes was occupied by a Locomobile contingent which consisted of President S. T. Davis, Jr., and Mrs. Davis, Mr. and Mrs. A. L. Riker and Mr. and Mrs. R. A. Greene. Before Robertson had his magneto troubles the Locomobile adherents were inclined to be fairly confident, though when the hard luck came, the situation was accepted heroically.

Equipment on the Winners—Tires, magnetos and carbureters receive their share of honors in victories such as those of the Buick and Chalmers-Detroit cars. Chevrolet's Buick used a Schebler carbureter, Remy magneto, and Michelin tires. The Chalmers-Detroit, driven by Matson, in the Indiana cup race, used a Kingston carbureter, Bosch magneto, and Michelin tires.

Of Course, John Farson Was on Hand—Resplendent in a suit of immaculate white, with red hatband and tie, John Farson, ex-president of the Chicago Automobile Club, was one of the shining lights. L. E. Myers, president of the Illinois State Association, and Sidney S. Gorham, who was secretary of the A.A.A. during Mr. Farson's administration, were also to be seen.

Ford and Firestone—Henry Ford, in company with Tiremaker H. S. Firestone, was a keen-eyed though quiet observer of the racing, which he admitted that he enjoyed thoroughly, even though his small car entrant was unable to be a starter. Seattle was Mr. Ford's destination in the evening after the finish of the Cobe race.

Happy Chalmerites—The Chalmers-Detroit camp was located at Lowell and here, after the small-car race, came Hugh Chalmers, Mr. and Mrs. Howard Coffin, Roy D. Chapin, Harry Ford, "Jim" Levy (of Levy & Whipple, the Chicago agents) and many others who believe in the car from Detroit.

Among Those Present—Of course, the list of real notables included such well-known figures as H. O. Smith, chairman of the A.M.C.M.A. executive committee; Alfred Reeves, the general manager; Samuel B. Stevens, now of the A.A.A. contest board, and Dr. J. B. Parks, of Boston.

Referee Paine Represented the Northwest—From one of the "Twin Cities" came the highest official of the day, Referee Asa Paine, a man well acquainted with the intricacies of automobile race management and once president of the Florida East Coast Automobile Association.

Chairman Hower Was an Onlooker—Chairman F. B. Hower, of the contest board of the A.A.A., was an unobtrusive observer of the sport, being in the company of F. C. Donald, president of the Chicago Motor Club.

President Cobe Presents the Indiana Trophy

FORDS AND SHAWMUT NEAR SEATTLE

SEATTLE, WASH., June 23—Ford cars and the Shawmut, in the race from New York to this city, are expected to reach here this evening or early to-morrow morning, and they are all within 125 miles of the finish. Ford No. 2 is leading, with the Shawmut second and the Ford No. 1 third. All three are out of the realm of telegraphic communication, but it is estimated that Ford No. 2 would have been ferried across Lake Kitchell late yesterday afternoon, would have run all night, and is now approaching the city. At 2:30 yesterday afternoon it was reported well along towards Snoqualamie pass; and at Ellensburg, 128 miles east of here, the Shawmut was reported yesterday morning as eight hours and 15 minutes behind the leader, but with its crew in better condition, and expecting to make up much time. The Shawmut passed Ford No. 1 out from Walla Walla, running well. The last report on the Acme was when it left Rawlins on Monday afternoon in good condition; and the Itala reached Denver on the same day, and prepared to continue northward.

The roads since leaving Rawlins have been very rough, often very bad, and once in a while good enough for fast work. The positions of the cars have not shifted as much as they did last week, when every car held the lead at some time en route, for the principal change has been in the overtaking of the Shawmut by Ford No. 2. The former left Rawlins four hours in the lead, but at Montpelier, Id., on Friday, Ford No. 1 arrived first, the other two cars having trouble 30 miles east of that place. They were quickly repaired, however, and the Shawmut secured a few minutes lead of No. 2. Ford No. 1 replaced a front wheel and a spring at Montpelier. On Sunday morning the Ford No. 2 reached Boise, and thereby won the $100 offered by the Commercial Club to the first arrival, for the other Ford had lost its way in the desert and its team-mate went into first place, the latter reaching Boise on Sunday afternoon at 2.30, and the Shawmut an hour later. In the race the matter of minutes became important as the contestants neared this State. Baker City, Ore., the only checking station in that State, was reached at 3.45 P. M. on Sunday by the No. 2 Ford, having covered the 160 miles from Boise in seven and three-quarter hours, and the crew pushed right on towards Walla Walla, 130 miles further. The Acme on that day was reported as leaving Boster, Wyo., where it had been held up by a broken jack-shaft.

That the cars were always on the go, is seen from the fact that the leading Ford reached Walla Walla at 6.45 A. M. on Monday, and after a rest of two hours pushed on towards this city. 291 miles further. The other Ford and the Shawmut were then en route from Baker City, the Acme had passed Rawlins, and the Itala had reached Denver. The roads from the position of the leader are good and local automobilists are awaiting a report of the cars to locate them, and then go out to meet them.

RUN TO WILDWOOD NEXT IN JERSEY

NEWARK, N. J., June 21—Members of the New Jersey Automobile and Motor Club still have two weeks in which to enter for the club run to Wildwood on July 3, but already enough have signified their intention of participating in this roadability affair to insure its success. The announcement of some very prominent entries in the straightaway races to be held at the shore has increased the interest in the week-end tour. Joseph H. Wood, chairman of the contest committee in charge of the recent amateur run, has announced that the club will conduct an open endurance contest under more rigorous conditions late in August or early in September, which will include a technical examination of the contestants at the completion of the event. At a meeting of the board of trustees, resolutions were adopted against the proposed "Jersey jubilee run" of some New York autoists, scheduled for July 1, 2 and 3. The promoters of this event plan to conduct it as a celebration of the passage of the amendments to the automobile law permitting out-of-the-State tourists to use Jersey roads for a nominal sum, and this method of expressing joy does not meet with favor in this city.

SAVANNAH NOW INTERESTED IN AUTO RUNS

SAVANNAH, GA., June 21—Endurance runs and tours are of greater interest to automobilists of this city at present than has any one thing been since the Grand Prize race. With the successful conclusion of the contest to Augusta comes offers of other termini, in the hopes that the Savannah Automobile Club will use its organized methods of management in conducting future events. Hon. Clark Howell, editor of the Atlanta *Constitution*, has offered to give over the management of the run to Atlanta to the local body, and a meeting of the executive committee has been called to consider it. This run is in line with the many proposed for the good roads movement, and would be an additional contest along the same campaign as that of the Savannah *News*. On Friday it is expected that about 150 automobiles will go to Atlanta for the inauguration of Governor-elect Brown, which occurs on Saturday, not only to give their owners and passengers the view of the ceremony, but also to get the new Governor well interested in the automobile and good road enthusiasm. The plans call for the start of fifteen cars from Fitzgerald, picking up others at Macon, Waycross, Thomasville, Perry, Jonesboro, and other places en route, while from every part of the State other cars will make the journey.

So far no word has been received from the Automobile Club of America as to a suitable time for a meeting between its contest committee and that of the local club. Savannah desires to prepare for another grand prize meeting, and awaits the cooperation of the New York body.

STODDARD-DAYTON WINS DELAWARE RUN

WILMINGTON, DEL., June 21—Thomas M. Brown, in a Stoddard-Dayton touring car, won the fourth annual roadability run of the Delaware Automobile Association, which was held on Saturday. The event was of the sealed-time variety, in which the cars were checked at certain points and the one which came nearest to reaching controls on time was declared the winner. Mr. Brown was penalized 24 points; second was W. L. Hammond, Mitchell, 28; third, A. B. Hazzard, Mitchell, 29. There were 23 starters for Dover in the morning, and of these 18 finished. The route took the contestants to Dover and back. Those others who finished were: W. H. Jones, Rambler; G. S. Woodward, E-M-F; Dr. J. C. Fahey, Stoddard-Dayton; Mrs. J. C. Moore, Cadillac; T. C. Bradford, E-M-F; H. F. Dougherty, Ford; C. M. Beadenkoph, Cadillac; C. B. Harris, Cadillac; W. J. Gibbons, Franklin; J. B. Bird, Franklin; R. S. Baird, Stoddard-Dayton; W. E. Anger, Autocar; E. E. duPont, Stoddard-Dayton; Mrs. E. E. duPont, Buick; R. T. Elliott, Buick.

LONDON'S OMNIBUS TRAFFIC STILL DECLINING

In the last available figures on the subject of the omnibus traffic in greater London, it is apparent that the traffic is still low and does not rise as it was expected to do. For the week ending May 29, while the traffic increased but £5,164 ($25,820), the total for the year up to that date showed a loss of £32,051 ($160,255), this amounting to 4.4 per cent decrease. In the same time for the Tubes showed an increase of £14,528, and the figures for Tramways revealed a gain of £60,488. Added to this the increase on the part of the Shallow Railways of £33,465, make the omnibus situation particularly noticeable. Against the handsome gains on the part of all other methods of transportation this is sufficient to bring the total gain for the year for all systems down to £76,430, equivalent to but 2.9 per cent.

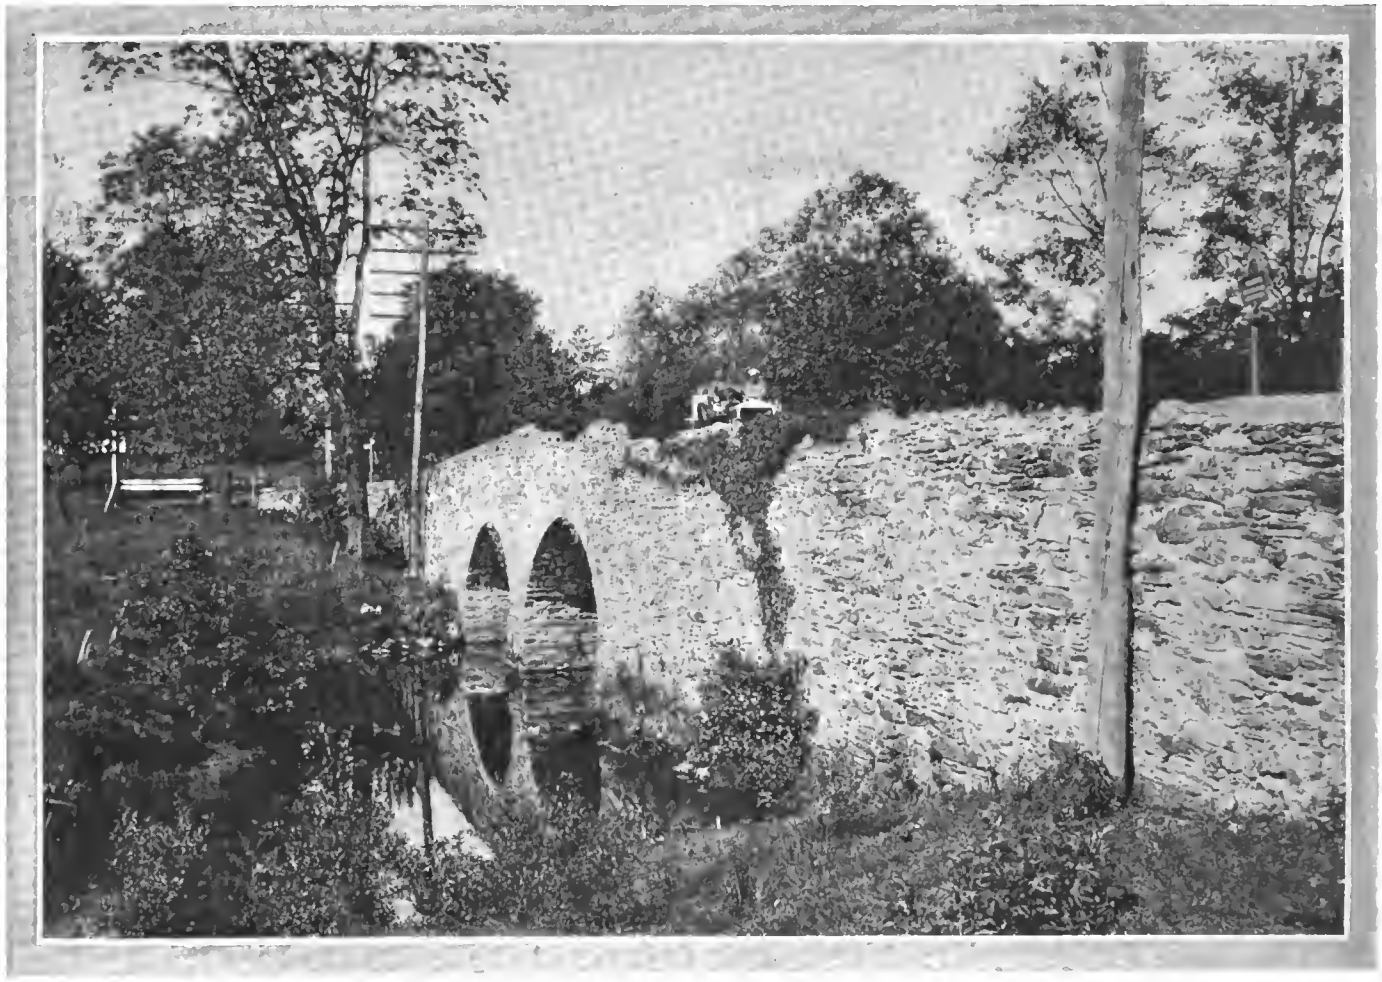
NINE CONTESTANTS IN BINGHAMTON RUN

BINGHAMTON, N. Y., June 21—Nine contesting and one official pilot car left this city this morning on the fourth annual tour of the Binghamton Automobile Club. The route includes night stops at Albany, Boston, Hartford, and Newburg, returning to the starting point on next Saturday.

MAKING OF AN EPOCH IN GOOD ROAD CONSTRUCTION

By COKER F. CLARKSON, A. L. A. M.

THERE is under way a movement going to the foundation of things in the good roads matter. To many good roads are an uninteresting and hackneyed subject. But of their vital necessity and of the advisability of constantly urging their construction, there should be no debate. No other improvement will pay to the people such dividends as modern highways. A nation's reputation for enterprise, progress and all that goes to make it worth living in, is determined very largely by the character of its roads, the great arteries through which flow the business and pleasure of the nation.



Where the Highway That Leads from Trenton to Philadelphia Crosses a Picturesque Bridge at Langhorne, Pa.

The public road is a principal feeder of our civilization. We take pride in our crops and products, often forgetting public roads must bear them to market. We lead the world in railroad building, but for every mile of railroad we have ten miles of highway, such as it is. Perhaps this in a way indicates the relative importance of improved highways.

The benefits to be derived from a reasonably good common road system would be shared by all classes: the farmer reaping a better profit through easier transportation to commercial centers; the inhabitants of towns and cities by the product of their labor reaching the rural districts more economically. This is a fair analogous deduction from the history of the reduction of freight rates by the improvement of roadbeds and rolling stock, to which much of what science, experience and invention have developed has been applied.

The history of good road construction all over the world reveals only a few fundamental methods. The Romans laid down large flat stones. Then in France rough stones were set on edge, a layer of broken stone being superposed. A similar theory was later followed in England. Early in the nineteenth century McAdam announced the principle that small pieces of broken stone placed in a layer are, by the action of water and travel, transformed into a homogeneous road surface. Years afterward the road-covering effect of crude oil became known.

It is now pretty generally recognized by highway engineers that the macadam road is, for modern conditions, obsolete, and that from now on first-class roads must, by the admixture of proper ingredients, have a mastic property, by virtue of which dustless roads will become a reality, and undue depreciation from disintegration of the road be avoided.

The good roads problem, although precipitated by the automobile, has been left alone for generations, and extends in its far-reaching importance and effect much further than the consideration of its relation to the automobile; in fact, as far as any economic question can reach. The automobile is broadly a medium of communication and traffic, upon which the very life of the nation depends. Roads are simply media for facilitating traffic, incidental to animate and mechanical road traction, and not an end in themselves. This last should be obvious, but some seem to think the preservation of roads out of date for modern purposes is the great desideratum. But progress in fundamental matters cannot wisely be impeded by incidental considerations. It is clear that the automobile is an improved method of accomplishing a fundamental function.

Indicator Cards and what they Delineate

BY THOS. J. FAY

INDICATED HORSEPOWER, referring to a motor, differs from the actual delivered power by the mechanical losses. Just what the mechanical losses are is largely dependent upon the design of the motor in any given case and because of this fact the indicator becomes of the greatest value for, by its use in conjunction with a dynamometer, it is possible to ascertain not only the power that a motor will deliver, but the losses mechanically, so that the best speed at which to gear the motor with a view to the highest fuel efficiency will be arrived at.

The indicated horsepower of a motor will depend upon the factors as follows:

Let

P = mean effective pressure in pounds per square inch.
L = length of power stroke in feet.
A = area of piston in square inches.
N = number of power strokes per minute.

When

$$\text{I.H.P.} = \frac{P\,L\,A\,N}{33{,}000} = \text{indicated horsepower.}$$

The length of stroke and the area of the piston, since they are dimensions of a motor that do not change, can be ascertained with good accuracy at will, while the mean effective pressure, as well as the speed, are the two factors that cannot be fixed offhand. It is common practice to assume that the speed will be, say, 1,000 revolutions per minute, but this practice is without any good foundation at all, on the ground that the speed depends upon several considerations that cannot be arrived at excepting as the result of an actual test after a motor is built, although it is possible to approximate the speed performance in the process of design if the problem is approached in due form.

At all events, when a motor is finished and it is desired to ascertain just what it will do it is the indicator in some form or other that is adopted with the view of procuring what amounts to a photograph of the curve of pressure of the gas in the cylinder during the several cycles, and since the curve can be measured, it is possible to determine the mean effective pressure throughout the strokes. The same photograph (card) will tell if the suction pressure is excessive; if the valves open early or late and if the ignition is adequate and properly timed. There is also the back pressure to be disposed of if it is sufficient to reduce the power of a motor beyond a slight amount and if the muffler is not good for the purpose; by means of the indicator it is possible to ascertain the fact by the simple expedient of taking off a card with and without the muffler.

Indicators as they are used in steam work are not so well adapted to such high speeds as when automobile motors of the internal combustion genera are to be investigated, and the modern method involves the use of a "manograph," diagrams from which show exactly the same information as that obtained from indicators of the conventional sort, excepting that the accuracy of the manograph is its best recommendation notwithstanding high speeds of the motor to be tested. Since the cards in each case are of the same general character it will be unnecessary to describe either of the forms of equipment at this time, rather with the expectation that these matters will ultimately be afforded a measure of space for their proper elucidation.

Typical Indicator Card Showing Characteristic Points—Before technically discussing manographs used to bring out the points to be made a typical card will be exposed for the purpose of rendering the text clear. The card, Fig. 1, is therefore offered, and as will be observed, the stroke of the piston is depicted by the line A B at the atmospheric pressure, which is 14.7 pounds per square inch (closely); the distance A C is equal to the clearance between the top of the stroke and the dome of the combustion chamber. The compression line is shown from the point B to the point of convergence into the explosion line, terminating at E, and the expansion line, extends from E to B. On the suction stroke the line of pressure shows below the atmospheric line, difference in pressure being but slight in the better types of motors. The exhaust on the scavenging stroke is a maximum at the point B and should fall away to the pressure of the atmosphere at the point A; this is rarely true in practice, especially when a muffler is used, provided the same silences the noise of the exhaust as perfectly as is the wont of the average autoist. The power that can be taken from one cylinder of a motor is equal to the area of the enclosure of the compression, explosion and expansion lines, from which must be subtracted the area of the enclosure of the atmospheric and the admission line together with the area of the enclosure of the atmospheric and the exhaust line. The power so found will be indicated, from which must be subtracted the mechanical losses of the motor, including the power required to drive the accessories, as pumps for oil and water, also the magneto used for ignition purposes. A planometer may be used for the purpose of ascertaining the area of the surfaces enclosed by the respective boundaries and the strength of the spring used in the indicator must be considered in the process of determining the power of the motor in a manner as will be shown in the discussion relating to instruments and measurements. The power above alluded to does not take into account the losses in the transmission system, as clutch, gears, differential, bearings and from vibrations.

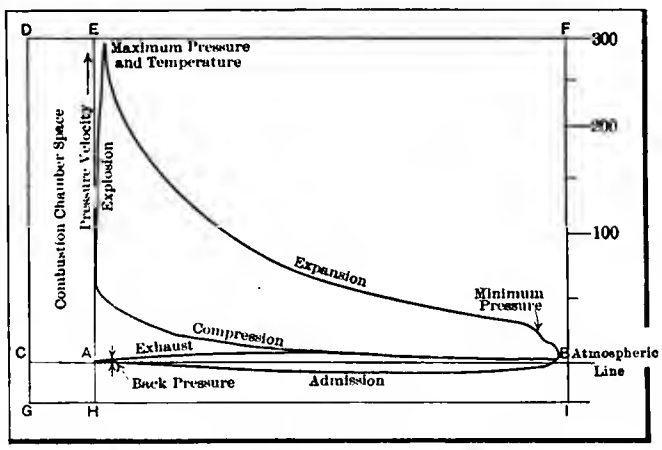


Fig. 1—Characteristic indicator card for use as a key to the cards as shown in Fig. 2

Practical Results as Depicted on Cards—These diagrams, as shown in Fig. 2, were originally taken for the purpose of determining the efficiency of sparking equipment in some experiments conducted by W. Watson, and a paper by him was discussed before the Automobile Club of Great Britain bearing upon the ignition phase of the situation. The cards, however, portray much more than was brought out at the time and they are unusually good for the purpose. The motor was of the 2-cylinder type, 3 1-2 by 4 inches bore and stroke, respectively, and the speed of the motor was

held between 950 and 1,000 revolutions per minute while the cards were taken off.

Two diagrams are shown on each plate, marked a and b, respectively; effect of energy in the spark is shown at a glance, for the second diagram on each plate was taken with a weakened spark in each instance. The cards designated as (a) were taken with the strongest primary current that would afford results on an increasing basis and the diagrams marked (b) were taken with the weakest current in the primary of the coil used that could be employed and not have missing explosions during the poriod of operation.

In this experiment the sparking distance was tried out at .25, .5 and 1 millimeter with little or no difference in result, so that the final work was conducted with the sparking distance held at .5 millimeters separation. This is one of the matters that would naturally show up on an indicator card, and it is well worth noticing that the spark-gap may vary over broad ranges without affecting the efficiency of performance of the motor. In the case of the card B it will be observed that the diagram (b) is imprinted twice, one of which is with a higher explosion pressure than the other by a considerable margin; this was due to the scavenging effect of a "miss," the explosion that followed the "miss" was relatively violent, due to the better conditions of scavenging, and this is one of the best points to be determined in an investigation of this sort.

The card C shows the result of excess air dilution, in which it will be observed that the highly inflammable charge was fired quite as well with the weak spark as with the spark that emanated from a strong current. In this case, however, the explosion pressure was below that which would be produced were the mixture normal in view of the compression pressure shown, which was relatively high, thus indicating that the ratio of explosion to compression pressure is neither constant nor to be relied upon if the ratio of gasoline to air is altered sufficiently to lower the rate of flame propagation very much. On the other hand, this card shows that the best fuel efficiency will fall somewhere in the vicinity of the mixture that will propagate a rapid flame, and sparking troubles will so be much reduced in such cases; this card shows that the spark does quite as well when weak as when strong if only the mixture holds enough excess oxygen to render it quick burning. On the other hand, excess oxygen can be overdone, in which event the mixture will not be quick burning and the weak spark will fail to perform in a satisfactory manner.

What the several cards show, from the point of view of suction pressure, is a certain uniformity, rather than any very definite results; as an example of an appreciable area of the suction portion of the diagram, it is possible that the examples B and I are the most conspicuous; the depression, below the atmospheric line in these cases, is sufficient to warrant the belief that the motor was contrived with quite small valves, and that the intake was somewhat restricted in area, or the carbureter was of the class to afford easy starting of the motor, rather than efficient power service. That there is a vast opportunity to engender losses in a motor by having a considerable depression in the intake is one of the matters that will be fully illustrated if the exponent "N" is calculated for the several depressions. It has been shown in another place that the compression is affected by the numerical value of the exponent named, which exponent is not far fram 1.3 when the depression during the suction is 1.7 pounds per square inch, making the absolute pressure 13 pounds per square inch. In a general way, when the suction pressure is pronounced, it is desirable to ascertain if there is some way to free the suction, sufficiently to lower the suction pressure, with-

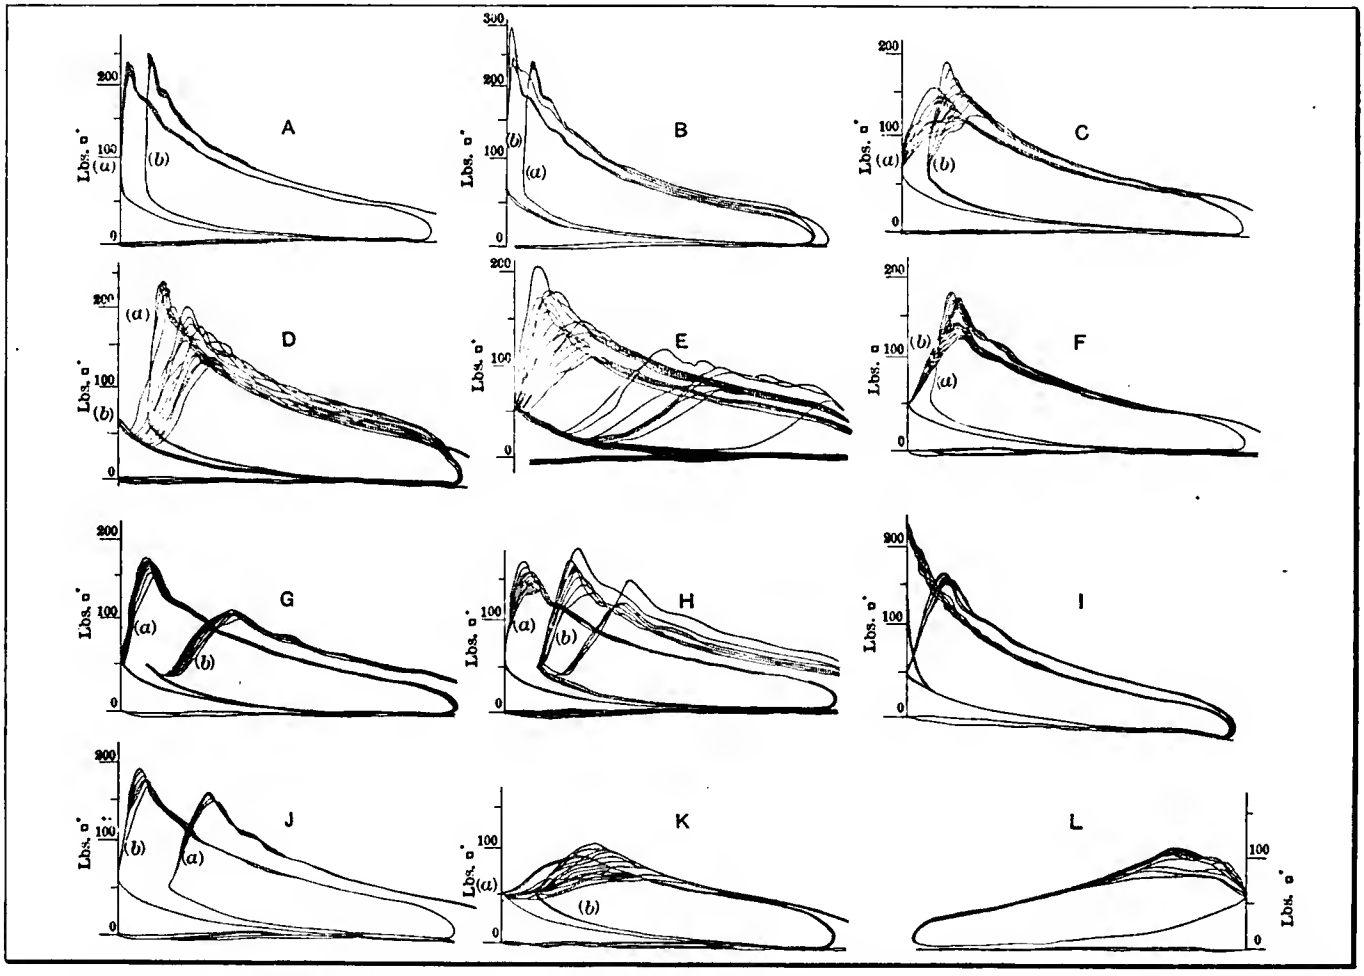

Fig. 2—Indicator cards showing the effect of early, late, weak, and strong ignition; also the usual variations that influence power

out, at the same time, reducing ability to start the motor, or undue cranking. Of course, there are two sides to this question; if the suction pressure is insufficient to afford a full measure of mixture, the power of the motor will fall off in response to the diminished weight of the same; on the other hand, if the pressure is excessive, it will show in any attempt to balance the cyclic losses, the one against the other. If the suction pressure is, say, two pounds per square inch, this negative pressure must be compared with the mean effective pressure on the power stroke. To compare the suction pressure with the maximum pressure on the power stroke, is to overlook the fact that the suction pressure is nearly constant over the whole stroke, while the maximum pressure, during the power stroke, is very much in excess of the mean effective pressure. If the mean effective pressure is, say, 70 pounds per square inch, which is not far from the truth in many cases, then:

as 70 : 2 : : 100 : 2.85

This is a rather large proportion, which, in the absence of other losses, would be a small matter; the back pressure, however, must be considered on the same basis. The diagram D is the only one that indicates the presence of any considerable back pressure, although, in motors in general, and especially when mufflers of an inferior character are used, the back pressure is material. If the losses of this character are indicated by the presence of, say, 5 pounds per square inch, back pressure, the proportion will look as follows:

as 70 : 5 : : 100 : 7.14

This, too, is on the basis of 70 pounds per square inch, mean effective pressure. What the cards do not show, is the differences in compression pressure that would follow changes in speed; since the speed was held almost constant during the "indications," and in view of the constant conditions, in other directions, the compression pressure was nearly the same in every case. The card I shows a lowered compression pressure brought about by pre-ignition. This is just what one would expect under such conditions, and it is but a step to the conclusion that very early, functional, ignition will bring about the same result in some measure.

One of the safe conclusions then, must involve a certain precision of ignition, such as can only follow if the ignition equipment is capable; free from a variable time constant; with an adjustable means for advancing and retarding, as the speed of the motor changes. It is on this account that electrical ignition systems are found to be of greater superiority than other means thus far tried; the difference in the several electrical contrivances, for that matter, are sufficiently noticeable to require consideration to obtain superior results.

Influences That Affect the Maximum Pressure—It will be observed that the maximum pressure is not the same in all cases; the variations are not even in a constant ratio to the variations in compression pressure; it is usual to assume that the maximum pressure is equal to about four times the compression pressure, in motors in general, under normal conditions of operation; this is an assumption that is not always borne out by the facts, excepting, perhaps, in a given motor, at some one speed. The diagram I shows that the compression pressure is about 50 pounds per square inch, and in this case the maximum pressure is about four times, or, 200 pounds per square inch. This compression pressure is low, due, as before stated, to pre-ignition. The card B shows a compression pressure of 60 pounds per square inch, and four times this value would equal 240; instead of this value of the maximum pressure, an observation will show that it was slightly under 300 pounds per square inch. The higher value, as above given, was after a "miss," thus indicating that the conditions of scavenging were superior to the average in this motor, and as a matter of fact, for this motor, it is very likely that the maximum pressure would be equal to about 4.5 times the compression pressure.

In this motor, the compression pressure was low, as shown by every card taken, due, in a large measure, to the constricted intake, and to some extent to the speed at which the cards were

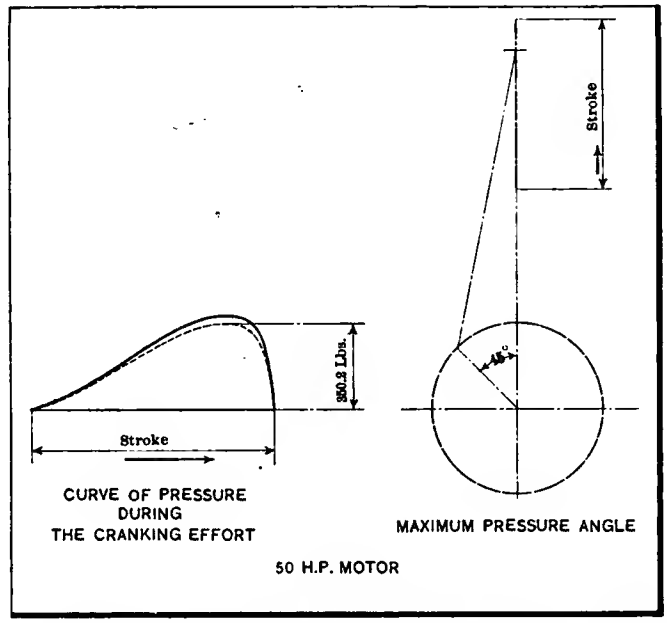

Fig. 3—Diagram showing the point at which maximum compression will show on the starting crank by inducing maximum pull

taken off. The card K indicated a very inferior condition of performance, the maximum pressure being about double the compression; this card was taken with a weak mixture. Against this, a glance at the card J will show the performance when the mixture was nearly normal, and it will be observed that the performance, as shown by J, was below the maximum expectation, due in this case to inferior conditions of ignition. In general, the ratio of maximum to compression pressure will be a maximum, under the conditions, as follows:

(A) The ratio will increase as the compression pressure is increased, up to a certain point, which point is at or near pre-ignition.

(B) The maximum pressure will obtain when the surface to the water (cooling) jacket is minimum, all other conditions constant.

(C) If the cooling provision is highly active, the compression pressure will be increased accordingly, and the maximum pressure ratio will fall off, but the mean effective pressure will be maximum.

(D) Bettering the conditions of scavenging will increase to maximum compression, as well, the mean effective pressure, without diminishing the compression pressure.

(E) Increasing the speed of the motor (the piston speed), beyond a certain point, will lower the compression; the maximum pressure out of proportion, and the mean effective pressure accordingly.

(F) Increasing compression, while it will have the effect of increasing the maximum pressure, will not produce a proportional increase in the mean effective pressure; the power of a motor, then, is not proportional to the compression pressure, nor is it proportional to the maximum pressure; the power is proportional to the mean effective pressure, however.

It was said, early in this discussion, that the speed at which a motor will do its best work is not to be assumed; it is no more possible to assume the speed than it is guess at the mean effective pressure. No two motors will perform in precisely the same way, in this connection, unless the features of design, and the conditions of operation, are in exact accord; it is even difficult to arrive at the same results when two motors of the same make, size, and even "shop order number," are tried out; it is on this account that one owner, of a given model of car, will realize good results, and another owner will receive but indifferent service.

The best speed of a motor is that which will afford the greatest measure of power, under conditions that will render the

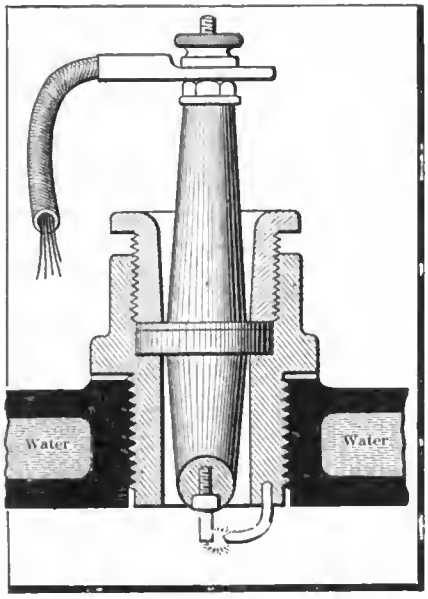

Fig. 4—Section of a sparkplug showing defective construction and loss of compression following the absence of packing

power available. In this will be found two points to be satisfied, i.e., the motor must be strong enough to enable the power to be taken off continuously, without damaging the mechanism; the gear ratio to the road wheels of the car must be such that the power available will be used up, and the demand must be no more. Indicator cards would be of the greatest value were it possible to rig up so that they could be taken with the car on the road doing its regular work, observing the speed at the same time. In this way, it would be possible to ascertain if the gear ratio accords with the requirements, remembering that a motor that is held down to a low speed, may not be delivering its best power.

Effect of Leaky Valves and Pistons—Since the amount of gas that will leak by, in a given time, depends upon the pressure, it is a simple inference that the leak is not at a constant rate, due to the fact that the pressure is not constant. If the mechanism is in a leaky condition, the compression will be lowered, but the most marked effect will be in connection with the explosion pressure; in taking off cards, it is possible to ascertain if the system is leaky, provided the ignition is cut off (from the cylinder to which the indicator is connected) and note is taken of the point at which the compression line crosses the atmospheric line. If the junction is far out on the stroke, it is a sign of a leaky condition, although, as before stated, the compression pressure will be deminished, due to the loss of mixture. With the ignition cut off, if a leak is present, the expansion line will fall below the compression line, due, of course, to lost mixture in the process of compression, at an increasing rate during compression, and in the process of expansion.

Effect of Over-heating May Be Noted—If the cooling system becomes inefficient, due to a faulty water circulation, as when the water pump becomes leaky, or if the jacket surfaces become encrusted, excess heat will rarefy the incoming mixture, and the actual weight of gas will reduce accordingly. The card will show a lower mean effective pressure than will follow if the motor is allowed to cool off, or if the water circulation is corrected; two cards, one with the system heated, and the other with the motor cooled off, will tell the tale, and the loss will be found to be considerable.

The torque of a motor is readily obtained by a dynamometer, and the fuel efficiency will be found to increase with the torque, just as does the power, at a given speed.

Torque will decrease:

(A) If the valves or the pistons leak;

(B) In case the cooling is inadequate;

(C) Provided the valves are not properly timed;

(F) When the intake is restricted;

(G) If the carbureter is too small;

(H) Due to back-pressure, as when the muffler is stopped up;

(I) If the ignition is not properly timed;

(J) In any case, when the speed increases enough to reduce the weight of mixture, due to friction of the same against the walls, and in a molecular sense as well.

If the system is leaky, the torque will be lowered at reducing speeds of the motor, due to increasing time, thus augmenting the loss of mixture; the torque curve will also slant in a downward direction as the speed increases, so that, in the average motor, after it has been in service for some time, it is to be expected that the curve of torque will slant downward at low as well as at high speeds, and indicator cards, at the several speeds, would show just such results, especially if the system becomes leaky, which is a normal expectation due to long service.

In actual practice it is possible for the average motorist to note the performance of his motor, from time to time, without having to resort to the use of an indicator, for the very simple reason that the cold compression will, in itself, serve to indicate the condition. From the point of view of leakage Fig. 3 represents the situation, in that it shows the maximum pressure angle, considering a certain motor, which should not differ much from motors in general, of the same power, and in this case, it was found that the maximum pressure (cold) came at 45 degrees, on the compression stroke, as shown by cranking the motor, as well as calculating for the curve of compression. A pair of scales, used to pull the starting crank up against the compression, is all that is necessary to show the value of the same at any time; hence, if the compression is reduced for any cause, it is possible to detect the difference. A gauge, attached to the cylinder, if it is provided with a stop, will serve as an indicator to go by, and a motorist, so equipped, will be in a position to check the performance of his motor, and if he finds that the cold compression is reducing, it is equal to saying that the power of the motor is diminishing.

Sometimes it is a small matter that causes a loss of compression, as a leak around a spark plug. Fig. 4 shows just such a plug, in which the packing is left out from under the seat where it presses down against the "boss" on the cylinder. The porcelain packing is indicated as above the enlargement, and the leak may also be up around the porcelain, and again, the packing is out from around the enlargement of the central electrode, thus allowing mixture to ooze by, and up along, the electrode. It takes but a very little leak to lower the power of a motor very much indeed, and the motorist who looks after this phase of the problem will rarely have to resort to the use of an indicator to ascertain why his motor fails to deliver the accustomed power.

One of the most mysterious leaks with which the motorist has to deal is due to sparkplugs, when they are new. Even if they are tight when they are first placed into service, it is highly improbable that they will stay so, and the proper measure is to tighten them up, after they get heated, allowing time enough for the packing to adjust itself to the heat that is normal to the performance. In this case reference is had to the packing in the entrails of the sparkplug, rather than to the packing ring that presses against the cylinder boss in consequence.

The indicator should be of the greatest advantage in affording more nearly exact information as to the right speed of a motor, or better yet, the timing of valves, and the spark that will give the best results at a given motor speed; certainly, it is not proper to time valves in precisely the same way, irrespective of the speed at which a motor is to run, when it is coupled into a car. The curve of torque of a motor is susceptible of manipulation, if the speed is adjusted, provided the valve timing is adjusted also, assuming that the camshaft is so suspended between bearings that it will not spring so as to destroy the setting of the valves, and if lost motion is eliminated.

A given car, of a certain weight, and of characteristics that are fixed independently of the motor, will take a certain amount of power to impel it, no matter what may be the character of the motor used. If the motor is not big enough to do the work, the car will not run, because if the motor is incapable of exerting enough twisting force, it will shut down. In setting a motor then, it is necessary to consider the power required; gear ratio, in view of the road conditions that have to be tolerated, and the service that the car is expected to perform, and if great flexibility is one of the prime requirements, the curve of torque must be examined.

KINKS AND WRINKLES FOR THE AUTOIST

By D. R. HOBART

UNFORTUNATELY for those who tour any great distance from home, repair shops are few and far between in many sections, and too often the local Vulcan is ready to attempt repairs but lacks the necessary ingenuity to cope with unusual cases of trouble. If the autoist does not possess skill in inventing remedies for such cases, and is minus the necessary spare parts, he is reduced to the ignominy of leaving his car in the care of the repairer and making a journey to the nearest agency for that particular make of car to replace the broken parts. Again, he may encounter the trouble on a comparatively deserted road and will have to wait for a tow from some passing team.

Efficient Spares and Tools to Be Carried—Occasions necessitating repairs are by no means of such uncommon occurrence as might be supposed considering the refinement and care in construction given to automobiles of the present day, but these facts in no way justify any autoist, whether novice or "old hand," from taking precautions in the shape of spare parts and tools against trouble of any nature. Before starting out on an extended tour at any time the box or bag devoted to spares should be examined and if any are defective, others should be substituted for them. The writer suggests the carrying of the following spares and tools in addition to the regular outfit as sufficient to cope with a large majority of roadside troubles: twine, tire tape, copper wire, spare springs for valves, rubber bands, hand vise, medium Stillson wrench, small blow torch, soldering iron and solder, brace and several drills, drift, cotton waste and a pair of gloves for working. Some of these are included in first-class kits but the autoist would do well to obtain them all as there is no telling when they will be needed to enable progress of any nature to be made.

With regard to the tools carried, there is no economy in cheap wrenches, files, etc., and sad to say, many tool-kits supplied with automobiles contain puny hammers, lead files and chisels whose edges are destroyed at the first stroke of the hammer. Such tools should be gotten rid of as soon as possible and others of well-known and tried makes put in their places. If the autoist is in doubt as to what make of file or wrench to purchase, any machine shop can give him satisfactory answers.

Interchangeable Valves Handy in Case of Breakage—An exhaust valve breakage was formerly a serious affair, as unless the autoist had a spare valve along, he was obliged to limp home on one cylinder when he had a two-cylinder motor, or be towed if the motor had but the one cylinder. Until recently, inlet and exhaust valves were of different sizes and could not be interchanged, but there have been comparatively few motors turned out in the last two years in which the valves are not of the same size. With motors having valves thus interchangeable, when an exhaust valve breaks and no spare valve is at hand, the inlet valve can be removed and put in place of the exhaust and the broken exhaust valve made to operate as an automatic inlet valve. In making all such interchanges, the valves must be ground in on their new seats.

When the Break Occurs Below the Guide—In many cases when the break occurs below the guide, the stem parts through the slot. To enable the valve to operate automatically a hole is bored in the stem or a slot filed in it in a radial direction. The slot and hole are for the attachment of retracting springs, two of which are shown in Figs. 1 and 2. In the first figure, A is a flat spring which works caliper-fashion in seating the valve, its upper end being fitted into a slot B filed or cut in the valve stem while the lower end is pierced to accommodate the lifter casing set-screw C. The "spring" in Fig. 2 is an elastic band A fastened to the screw at one end and to the valve at the other by means of a cord B passing through a hole drilled in the stem.

Weight of Valves Militates Against Easy Operation—In repairs such as the above, it must not be expected that the valves will operate as well automatically as when mechanically operated. Valves intended for mechanical operation are made heavier than those designed to work automatically, and the increased weight militates against their easy operation. Retracting springs have to be sufficiently light to allow the valve to lift under the action of the suction, but not so powerful as to slam it back on the seat when suction ceases. With the arrangement in Fig. 2 other bands can be added in case the tension is not strong enough but in Fig. 1 tension can only be regulated to a certain degree by increasing or diminishing the "cup" of spring A. The shorter the valve stem, the lighter will be the valve and the more readily will it lift, it should be remembered. The time needed in effecting either of these repairs is about 15 minutes, not including the grinding in of the valve. With a single cylinder motor, the valve will work sufficiently well for the autoist to proceed to some place where a new valve can be obtained. With a two-cylinder motor, much time and annoyance will be saved as limping along on one cylinder is slow and by no means sure. In multi-cylinder motors difficulty will be experienced in having

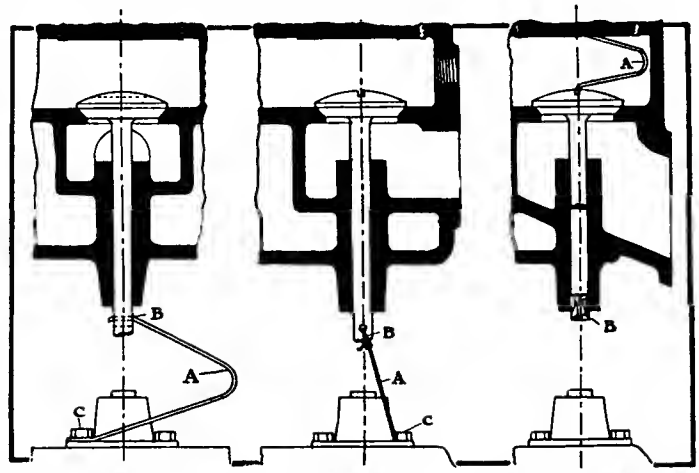

Fig. 1—Flat spring repair Fig. 2—Elastic band repair Fig. 3—Spring in the valve chamber

Utilizing Broken Mechanical Valve as an Automatic Valve

the "automatic" valve synchronize with the other mechanical valves but good progress is possible, nevertheless.

When the Break Is Within the Guide—In Fig. 3 is shown a repair when the stem is broken off in the guide. A spring A is placed within the valve chamber, one end in the slot in the valve head and the other bearing against the valve cap. The guide is plugged as at B to prevent air being sucked into the cylinder and weakening the mixture. Only in case of extremity should this repair be employed, as the spring will lose its temper or break and fall into the cylinder. It will, however, last a few miles, in some cases long enough for the car to reach a repair shop. In putting spring A in place, its upper end should bear off-center so that it will not be shot into the cylinder at the first suction stroke. If the requisite appliances are at hand, a hole can be tapped in the end of the stem and an arrangement of elastic bands like that in Fig. 2 attached to a screw set in the tapped hole. The plug in this case is to be left out.

A Practically Permanent Repair—Better and to all intent more permanent than the preceding when the break is at or above the slot, is the repair shown in Fig. 4. Provided there is sufficient space between the water-jacket and the broken end for the action of at least three spirals of a spring, this repair can be made to any mechanically-operated valve. A thread is formed on the stem at its lower end and two lock-nuts DD are screwed thereon, a flat washer E being put above the nuts to take the thrust of the spring. Spring C is cut off sufficiently to operate

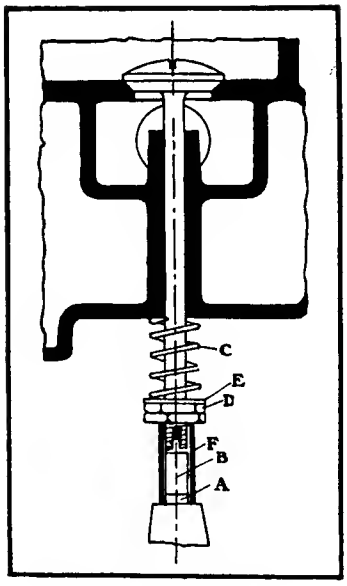

Fig. 4—Repair by insertion of filler piece

the valve without excessive strain on the cam as would be the case where the full sized spring was used in the restricted space. A piece B whose length is equal to the distance from the lifter A to the end of the stem minus the clearance when the valve is closed, is put in place on top of A and a short piece of tubing F put around both B and A to prevent the former from hopping out of place when the car is running. Clearance should be left between F and the lower lock-nut to prevent deformation and possible binding of the filler-piece B within the tubing. The advantage in such a repair is that there need be no grinding in as the broken valve is used in its proper place. The appliances necessary to effect this repair, die, lock-nuts, tubing and filler-piece are not often found in an autoist's tool-kit, so that the operation has usually to be performed in a repair shop. With steady attention to the work and the material at hand, thirty minutes should be all the time needed to complete the repair. In a similar way a broken mechanically-operated inlet valve can be adapted to automatic operation, the tubing F and the filler-piece B not being needed in this case.

Break Close to Head Impossible of Reliable Repair—There is little use trying to repair a valve broken off close to the head. A spring put in the valve-chamber as in Fig. 3 will be of very doubtful service and while it may return the valve to its seat the danger of having the head sucked into the cylinder is too great to warrant the use of such a make-shift. With a single cylinder motor therefore, the autoist will be obliged to lay up the car until a new valve is to be had. With a multi-cylinder motor the inlet manifold should be removed, the port of that particular blocked by means of a piece of cardboard, heavy paper or sheet gasketing, and the manifold replaced, care being taken in replacing that there will be no leak at the joints due to the extra thickness of gasket on the blocked cylinder. The spark plug should be taken out of the "dead" cylinder to allow the air compressed by the piston to escape freely. In motors where the inlet manifold is integral with the cylinder casting such as is the case with certain forms of "block" motors, the broken valve should be placed on the inlet side and prevented from lifting by a block of wood of sufficient length to keep it seated when the valve cap is screwed down.

When the Starting Crank Is Inoperative—On all cars with the motor in front the starting crank is permanently attached to the car, so that it is only necessary to push it inward against the action of a spring to engage the dogs with the pin on the extension of the crankshaft. This pin is subjected to considerable strain and sometimes breaks off, leaving the autoist to start the motor in some other manner. A method of starting which requires no extra appliances consists in jacking up one rear wheel of the car, and after engaging the high gear and letting in the clutch to turn the wheel strongly and rapidly in the forward direction. When the motor starts, which it will do with surprising ease, the clutch should be drawn, gear shifted to neutral and the wheel lowered to the ground. The car will then be ready to proceed. In some cases it will be necessary to set the hub brakes after the clutch is drawn, in order to stop the spinning of the jacked-up wheel.

Removing Broken Screws and Studs—Occasionally a screw or stud breaks off close due to too strenuous application of the wrench or in a futile endeavor to start the refractory piece with a hammer. There is not enough of the broken end projecting in most cases on which a grip with the jaws of a pair of pliers can be obtained, so that one of the following methods must be employed to withdraw the stump of the screw. If possible, a slot may be cut in it for a screw driver, but the break is so often below the level of the part into which the screw is set that this cannot be done. This being the case, a hole should be drilled in the stump and the tang of a file inserted so that it bears against both the side and bottom of the hole. On rotating the file the stump will usually come out, especially if the threads have been treated with kerosene. If the stump refuses to move, the hole should be tapped with a left-hand thread and on screwing in a left-hand screw the broken piece will be drawn out. The employment of a left-hand flat drill in drilling the hole will often bring out the stump without the necessity of tapping. As a last resort, a hole of as large diameter as possible without injuring the threads should be bored through and the shell remaining chipped or cut out. It would be well to go over the threads of the part from which the screw was removed in this manner with a tap to correct any deformation caused by the chipping or cutting.

Substitutes for the Funnel—Autoists when starting on a tour should make sure that a funnel is included in the list of accessories accompanying the car. There are some autoists who never carry such useful articles on the ground that wherever gasoline is purchased a funnel will be supplied, so why carry anything that is not necessary? Anyone that has toured extensively in sections considerably removed from the larger cities, where garages are few and far between, knows the habits of country store-keepers, how one funnel is made to do duty in delivering molasses, water and oil as well as gasoline and is often given no better care than an occasional rinsing. The effect of foreign substances in the gasoline is well known and their effect on the action of the motor soon after their introduction into the fuel system will indicate their presence, so that an autoist who relies on gasoline delivered through unclean vessels is running chances of being laid up on the road and having to go through the tedious operation of cleansing the carbureter and perhaps the entire fuel system. One funnel at least should be carried, therefore, for use with gasoline and to insure cleanliness, this should be fitted with a strainer. A second funnel could be advantageously carried for filling the radiator, but the occasions when water is needed in the circulating system are so infrequent that this funnel is not absolutely necessary. However, if a funnel is not at hand when needed, the autoist can use an old envelope from which one corner has been torn, the envelope being held as in Fig. 4, where C is the opening made by the torn off corner. A handkerchief placed in the filling aperature will act as an efficient strainer, or still better a piece of chamois can be used. An excellent guide for pouring in liquid of any kind can be formed from a tire gaiter, squeezing one end so that the two sides form a channel sufficiently small to prevent slopping over the filling aperture. It is of course understood that the gaiter is to be cleaned before being used for this purpose. Wrapping paper rolled into a cone, or a portion of an inner tube will also serve to conduct liquids in the absence of a funnel or a rubber hood formed into a trough can be used in emergencies.

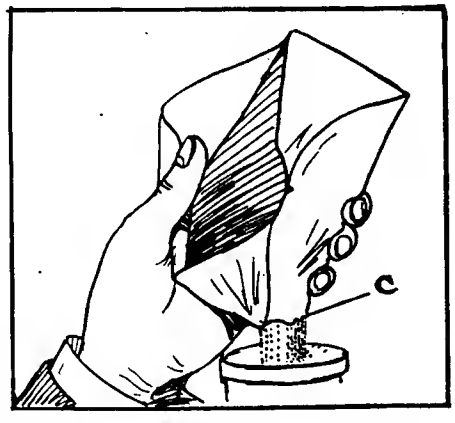

Fig. 5—Envelope used as a funnel

LETTERS INTERESTING AND INSTRUCTIVE

WHAT MAKES IT JUMP?

Editor THE AUTOMOBILE:

[1,921]—Will you please tell me through "Letters Interesting and Instructive" what makes my runabout, of a popular model, jump at times when running on the high gear, especially when the car is being run very slow. I have tried several things, such as valves, carbureter and commutator, but have not corrected it yet. I would like to have instructions as to how to time valves so as to get the best power results, also carbureter and commutator. Why does the engine get hot at times more than at others?
Clio, S. C. A. B. WELCH.

The make of car which you are driving and having trouble with is equipped with a planetary transmission, which has a high-speed clutch. The jumping of which you speak might be due to some foreign substance on the surface of this, which prevented the clutch from engaging fully, yet allowed it to take hold sufficiently to drive the car. Then, after having driven the car for some distance, the obstruction was shaken out and the clutch took hold with a jerk, resulting in the jumping action of the car. This would explain the jumping of the car upon one or possibly two occasions, but not regularly, as it would be impossible to get obstructions into the clutch every day, as this would necessitate. You give so little information that it is hard to make out just what is the trouble.

As to the matter of instructions for timing valves, commutator, and remedying carbureter troubles, that is a rather large contract. You will find much to interest you and collect a great many pointers on the subjects spoken of if you read the following articles in the back numbers of THE AUTOMOBILE.

On Carbureters and Carbureter Troubles, Letter 1919, June 17 issue; Letter 1876, issue of May 13; Letter 1870, May 6 issue.

On Valve Timing, pages 897 to 899, June 3 issue; Letter 1901, June 3 issue; Letter 1883, May 20 issue (Offset crankshaft); Letter 1846, issue of April 22.

On Care of Valves, Letter 1889, May 27 issue; Letter 1869, May 6 issue.

On What to Do When the Carbureter Won't Work, pages 649 to 651, issue of April 22.

The engine may heat from a variety of reasons. The piston rings may be tight, the cylinder bore may be out of true, the water passages may be obstructed so that as much water does not reach the jackets as was intended, or faulty ignition or wrong carburetion may cause heating. A dirty cylinder oil may leave particles of dirt on the cylinder walls, which may cut and score the cylinder walls, thus causing heating. Then, too, the excessively high temperatures of the part of the country in which you are located may have something to do with the heating. If you could be sure that the latter was the source of trouble, substituting a light oil for water in the jackets would remove any possibility of this heating ever doing any harm to your engine. This would not remove the source of trouble, but would restore your peace of mind, for you would then know that no harm could come from overheating, whereas at present this may result in your pistons seizing, with much consequent expense.

If you should ever have this happen, that is, the pistons seize, the best thing to do is to immediately squirt a lot of kerosene into the top of the cylinder in question. This is very thin bodied as compared to lubricating oil, and will work its way down between the cylinder and piston, thus releasing the latter. In so doing, it will also lubricate the walls, so that the piston will not seize again immediately.

If this does not release the pistons it will be necessary to take the engine out of the car and by a liberal use of more kerosene and much brute strength, extract the piston from the cylinder. It will then be necessary to dress the piston, rings and cylinder walls up before they may be used again with safety.

GAS TURBINE PROSPECTS

Editor THE AUTOMOBILE:

[1,922]—Will you please tell me something more about the power of a gas turbine? I have a steam turbine, which can be so arranged as to cool both the moving and stationary blades with water. Now, what I want to know is, does this kind of engine develop the power? The cut shown in the May 27 issue of "The Automobile" is of a turbine, the blades of which cannot be water-cooled as mine can. My engine is not patented, but I have a small model which runs very well with steam. Do you think that it would pay to experiment further with this kind of an engine? C. V. FITE.
Gastonia, N. C.

If your device has an arrangement which allows of cooling both the moving and stationary blades, you have made a big step in advance, as this is one of the most vexing problems which inventors in the past have tried unsuccessfully to solve.

Considering that the power is in the fuel, latent so to speak, it is only necessary to devise an efficient machine to transform this latent power into rotary motion, to make the turbine form a very powerful source or energy in a rotary form. Of the three great gas turbine problems, namely, speed, heating of blades resulting in their dissolution, and gas tightness without friction losses, you appear to have solved one, and it would be advisable to continue your work along the same line. This, too, in preference to following the line of steam turbines, already well supplied with efficient and very successful prime movers of the rotary type.

VALVES AND DEAD CENTER

Editor THE AUTOMOBILE:

[1,923]—I have read Mr. Fay's articles on setting motor valves, particularly the June 3 issue, with great interest, but it seems to me that one very important point has been omitted, viz: setting the crank on the center.

Also, I do not consider the method in answer No. 1,897, in the same issue, a perfect one, as when the crank is nearly on the center the movement of the piston is so very slight that the periphery of the balance wheel can be moved several degrees without an appreciable movement of the piston.

A much better method is to make a tram from a piece of stiff wire with about half an inch of one end bent at a right angle and sharpened. Let the wire be long enough to reach some part of the frame so that it can butt against it, but always in the same place, having the point approximately at the center of the upper surface of the balance wheel. Now put one crank about 45° before the center and mark on the balance wheel with tram point. Measure how far bottom of piston is from bottom of cylinder, then turn motor forward until piston comes back to same point in reference to cylinder bottom and make another mark on balance wheel with tram. Find the center between these two marks and this center point, when brought to tram point, will put the crank on the absolute center. The other center will be half way around the balance wheel. Preserve the wire tram and the motor can be put on its center at any time.

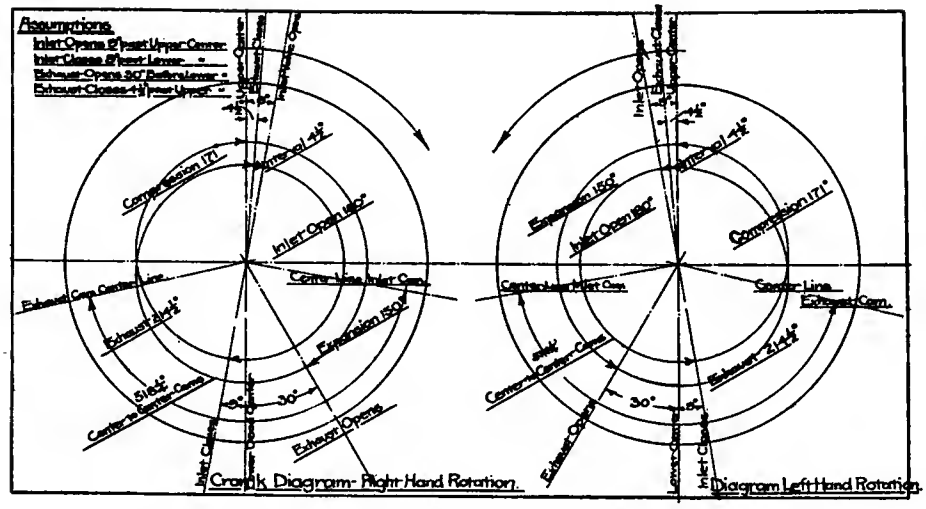
An easy way to find the opposite center is to take a strip of paper that will reach around the balance wheel and double, using one-half for a measure. W. W. TREVOR.
Lockport, N. Y.

Your criticisms are interesting, even though not just. The Fay article is not finished, and the matter of which you speak was not within the scope of that section. Later chapters may take up practical methods, such as setting the engine on the exact dead center, adjusting clearances, etc.

As to the letter, in which we presume that you have reference to No. 1,901, headed "Timing an Old Engine," rather than the one given by you, No. 1,897, which deals with, as the caption indicates, "The Subject of Weights."

In the former letter the subject of setting the engine on center was not discussed at any great length, because it was considered that nearly every one who could drive a car could also set the engine on center properly. Your answer raises the question that perhaps we were wrong in this assumption. It seems, however, as if the statement given in the answer to the letter in question, "carefully determine the upper and lower dead centers," covers the use and practice of any known method of doing this work in a manner which would come under the head of "carefully."

It might be well to call attention to one part of your remarks which would not come under this same head, and that is the last suggestion to find the opposite center by using a strip of paper which reaches clear around, folded in the center to measure half-way around. This would be far from an accurate method, and after determining the upper center by the careful and painstaking method given, it would be a



In Reversing an Engine, the Valve Diagram Must Be Completely Reversed

shame to spoil it by measuring around to the other center in the way mentioned. The circumference of an 18-inch flywheel is 56 1-2 inches. If a piece of paper as long as this will not stretch enough to throw away all of the accuracy of your former work we are very much mistaken. The proper way would be to take a steel tape, graduated into fine divisions, such as tenths and hundredths, measure the circumference, and then lay off half of that distance around in, say, a left-hand direction. Having done this, start around in a right-hand direction and lay it off again as a check. The measurements should agree exactly.

DETERMINING VALVE LIFT

Editor THE AUTOMOBILE:

[1,924]—Will you please give me a short empirical formula for figuring the lift of valves for automobile engines?
Cos Cob, Conn. SAM HEILMAN.

Having previously determined the valve diameter, bore, stroke, speed and valve seat angle, the area of the valve passages should be equal to the bore area times the stroke times the revolutions per minute, divided by the permissible speed, say 6,000 to 10,000 feet per minute. Then the valve lift should be equal to this passage area divided by the sine of the seat angle times the valve seat circumference.

HOW TO REVERSE AN ENGINE

Editor THE AUTOMOBILE:

[1,925]—Kindly inform me in the next issue of "The Automobile" if the following can be done: I have a two-cylinder, four-cycle automobile engine installed in a motor boat. This engine has the cams made integral with the camshaft. Now, I would like to run the engine in the opposite direction. Could it be done by changing the gears without having a new propeller wheel? The latter is a single casting, with right-hand blades cast integral. PIERRE LARIVIKE.
Champlain, N. Y.

Even if you could run the engine in the reverse direction it would be necessary to get a new propeller wheel to run left handed. Granting that you wish to go to this expense, the next thing to do will be to secure the reversal of the engine.

This is a big job and one that should be approached with due caution. First, you will need a new camshaft. This you may obtain from the manufacturer, or if that is impossible, you can have all of the cams for either the inlet or exhaust turned off and new separate cams made. The latter can then be attached to the old shaft in the proper place longitudinally and circumferentially, the latter being by far the more important.

It will be necessary to determine the present angle between the inlet and exhaust cams and on the new shaft; set the cams at that same angle, but in the reverse direction. To assist you in this a set of angles have been assumed, the two diagrams plotted, and the angles resolved into camshaft angles.

Two figures are given to help you. In the first, the valve diagrams are given for a supposed case, with the ordinary right-hand rotation, and also for the same case with left-hand rotation. Then in the second figure this latter diagram is resolved onto the cam diagram and the camshaft is shown as changed. To do this it was necessary to assume that the two cranks of your engine were set at 180 degrees apart and that you followed the suggestion made, to machine the inlet cams off from the present camshaft and make new ones to key on in their place, but properly located for left-hand rotation.

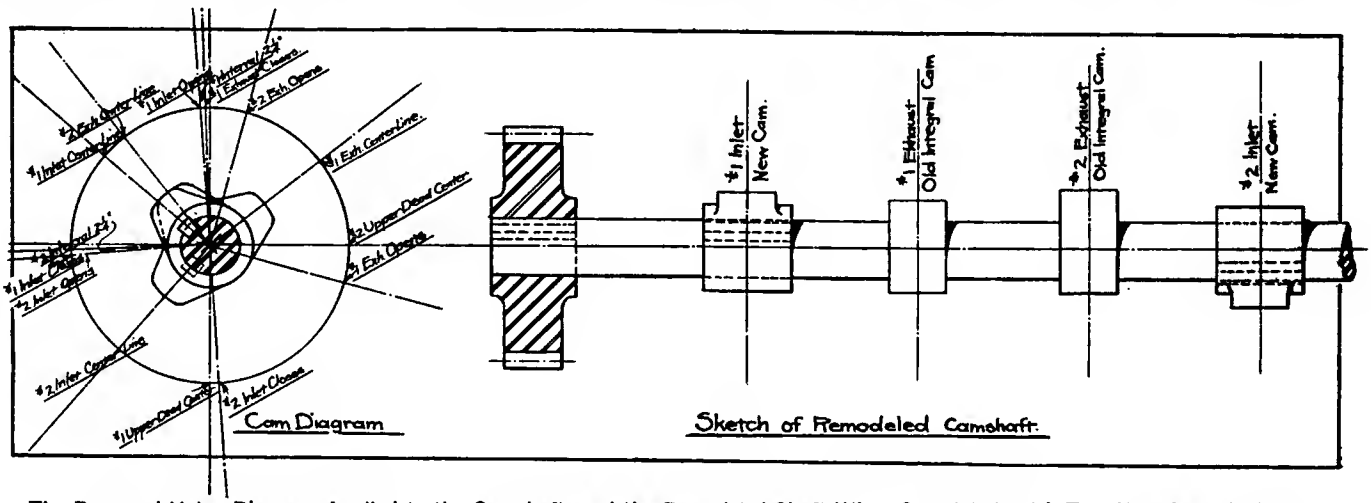
When all this has been done your work will be about half through, for it will be necessary to alter the timing of your ignition, whether that be battery, coil and timer or magneto. The former system is easier to change and this may be done by altering the setting and then changing the wires. With the magneto, however, it will be necessary to have an entirely new machine, these being built to run either right or left hand.

Then there will still be the pump. If this is a centrifugal pump it will be necessary to move it and insert another gear in the driving train so as to drive it in the same direction as at present, but with the engine running in the opposite direction.

If it is of the gear type no alterations will be necessary as these pumps are usually constructed so as to be reversible—that is, they work equally well both ways.

So, too, with the fan, lubricator and all other accessories they will have to be considered and such of them as are not reversible will have to be driven in a different manner. All told it seems as if the work and cost of this change more than offset any possible advantage to be gained from the rotation in the opposite direction.

Editor's Note—Will W. H. S., New York City, whose letter was published in the June 10 issue of THE AUTOMOBILE, kindly send his address to this office?



The Reversed Valve Diagram Applied to the Camshaft, and the Remodeled Shaft When Completed, with Two New Cams in Place

DESIGN OF KNUCKLE JOINT FOR TRANSMISSION*

By RUDOLF THUROW, M.E., Charlottenburg

THE absolute freedom of relative motion necessary between the motor and the gearbox of an automobile, where these two essentials are separate units, is usually accomplished by means of the interposition of the effective but costly universal joint. A more economical form of coupling is to be found in a knuckle type of joint or link, each end of which is inserted in a recess in the shafts, as shown in Figs. 1 and 2. The chief question about the design of such a joint is the determination of the size of the surfaces in contact and the pressure they are to bear. If the latter is to be high, the wear on the joint will be correspondingly rapid, while the stronger it is made in this respect, the more sudden and jerky will be the coupling in action. The entire turning moment of the motor will then be transmitted directly through the parts of the knuckle, which means that the parts will have to be proportioned with this idea in view.

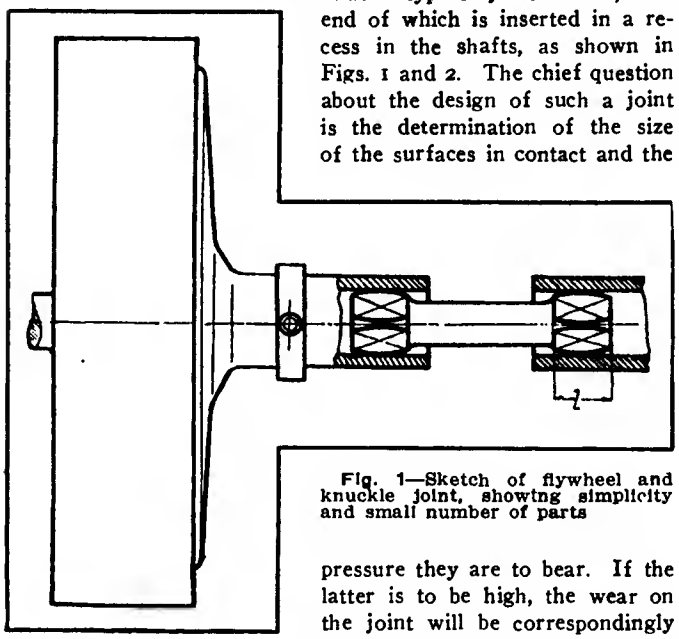


Fig. 1—Sketch of flywheel and knuckle joint, showing simplicity and small number of parts

This gives the relation:

$$N_e = \frac{Pv}{75}\eta \qquad (1)$$

The efficiency of the motor:

The speed v in meters per second $= \frac{2r\pi n}{60}$ (2)

and

$\pi = 0.8$ of the

$$N_e = \frac{Pr\,2\pi n}{60 \times 75}\eta \qquad (3)$$

Therefore it follows:

$$Md = \frac{N_e\,60 \times 75}{2\pi n\eta} \qquad (4)$$

In the knuckle joint, shown in Fig. 3, with a rectangular cross-section, the turning moment must be carried on four faces:

Consequently:

$$Md = 4P'r' \qquad (5)$$

or:

$$P' = \frac{Md}{4r'} \qquad (6)$$

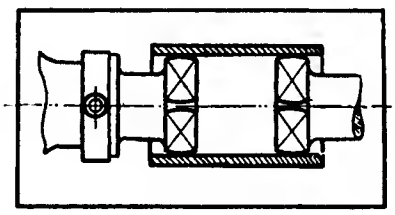

Fig. 2—Enlarged view of joint

*Translated from the German, by C. B. Hayward.

In actual practice, however, these stresses must be carried on about one-third of the surface in question, so that this reduces to:

$$r' = \frac{l}{3}b \qquad (7)$$

l is the length of the bearing surface, so it must be:

$$P' = \frac{b}{3} \times \frac{l}{2}k \qquad (8)$$

k represents the permissible deflection in kg/cm^2.

With a special automobile steel of good quality, it may be given a value of $k = kg/cm^2$.

For the knuckle link in question it may reach:

$$NC\,4\,I\,od\frac{C\,46\,O}{z}od\,K\,S\,72 \qquad (9)$$

But owing to the excessive stresses that will frequently occur and the resultant destructive effects upon the surfaces, it may often be considered expedient to employ more than four surfaces to transmit a certain amount of power. This brings us to the hexagonal cross-section illustrated by Fig. 4.

The equation is then:

$$P' = \frac{Md}{4r'} \qquad (10)$$

and it may reach:

$$P' = \frac{Md}{6r'} \qquad (11)$$

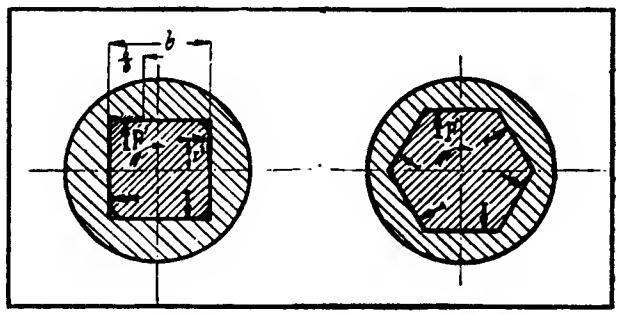

Fig. 3—Square type Fig. 4—Hexagonal type
Knuckle Joints Shown in Sectional Form

It will then follow that the pressure on the surfaces k will amount to but two-thirds of the value previously given, and it will hold that:

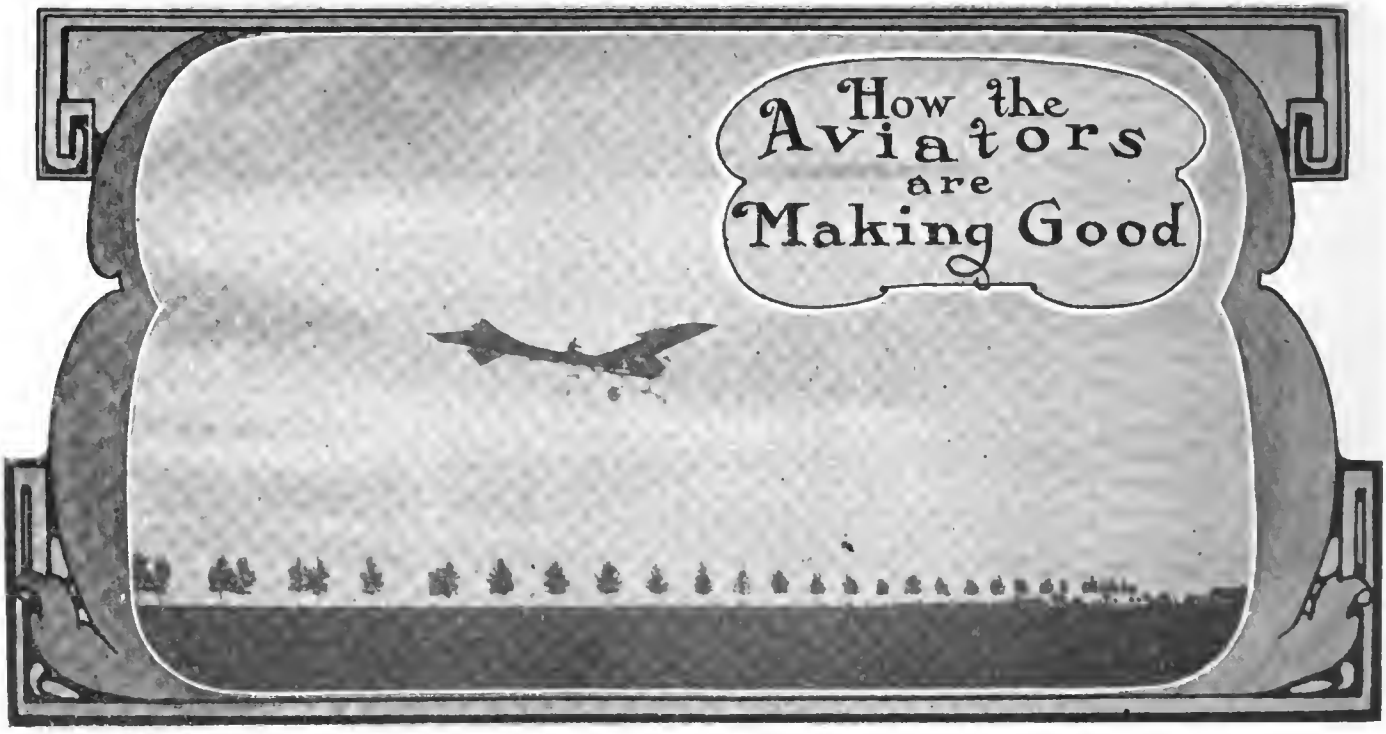
$$k : k' = \frac{1}{4} : \frac{1}{6} \qquad (12)$$

and consequently:

$$k' = \frac{2}{3}k \qquad (13)$$

The relation of the bearing surfaces in the hexagonal section is also much more favorable, but the six-sided construction naturally costs more. Practice alone can be looked to to determine the relative values of the square and hexagonal types.

Additional types are created by the extension of the number of faces to octagonal and higher forms, all of which present new problems to be solved. In the extreme this reaches the form of a gear meshing into another gear of the internal type. In practice this form is used with 12, 14 or 16 teeth, the number used depending upon local conditions, such as the allowable external diameter. So, also, with the width of the face.



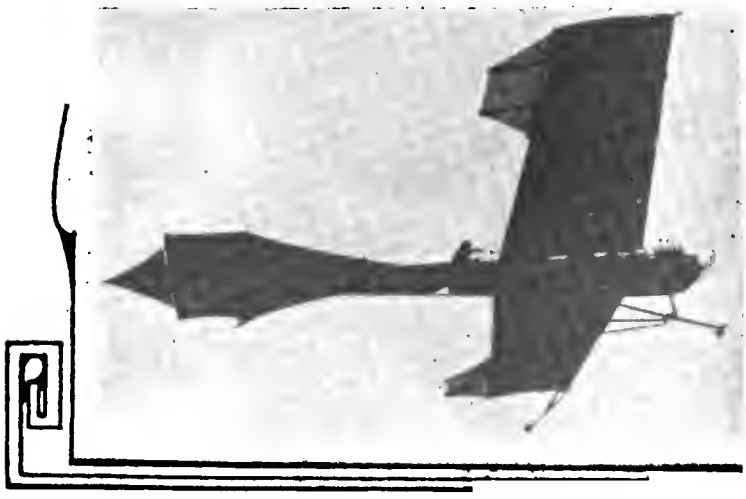
Hubert Latham, the English Aeronaut, with Antoinette Aeroplane, Breaking Monoplane Flight Record, at Chalons, France

PARIS, June 16—The present French aeroplane champion is an Englishman, who has succeeded, on an Antoinette aeroplane, in beating the record held by a Frenchman on an American flyer. Hubert Latham climbed into his Antoinette monoplane at Chalons a little before seven o'clock in the evening and did not settle down again until 1 hour 7 minutes 37 seconds later, having broken all records made in France with the exception of those of Wilbur Wright. First place in the flying world—excluding Wright, who is looked upon as unbeatable—had been occupied by Paul Tissandier, who remained in the air 1 hour 3 minutes on Wilhur Wright's old flyer.

Hubert Latham is a newcomer who purchased an Antoinette monoplane and took his first flying lessons about two months ago. Less than a fortnight ago he won the Aero Club prize for a flight of 500 yards, this being his first really important performance. This has been followed up by a flight of 37 minutes accomplished with such ease that on several occasions the pilot raised his hands from the steering wheels to take his cigarette from his lips. A steady breeze was blowing at the rate of 8 miles an hour when the start was made for the long distance record. After running 100 yards on the ground the machine rose into the air at a speed of 55 miles an hour, and at an altitude of 50 feet described huge circles over the vast plain. Later the height was increased to 130 feet, the flying machine passing over the tall poplar trees lining the military ground with a respectable margin of safety. When a descent was finally decided upon dusk had settled down and a drizzling rain had made it almost impossible for the pilot to pick out his course.

The long distance flight was followed by the winning of the Goupy prize for a flight of not less than five kilometers away from a specially prepared aerodrome or operating ground. Members of the Aero Club measured a straightaway course across country, planted a flag five kilometers out and sent the aeroplane away. There were telegraph wires, a village and poplar trees rising to a height of nearly two hundred feet, with the result that it was necessary for Latham to soar to a great altitude in order to be free from collision. Running at nearly 50 miles an hour, the aeroplane soared over the village of Cuperly, the inhabitants of which greeted him with shouts of delight, rounded the flag in 4 minutes 13 seconds, and after a very wide detour settled down at his starting point, having been in the air altogether no less than 14 minutes.

Captain Burgeat, also an Antoinette pilot, was next taken up as a passenger and carried for a distance of 800 yards; three others followed, the longest flight with a passenger lasting 11 minutes 56 seconds.



A Closer View of Latham's Bird of Flight

RHEIMS AERO COURSE PREPARATIONS

PARIS, June 10—The Gordon Bennett and other aeronautical races to be run during the Rheims week, August 22 to 29, will take place round a specially prepared course marked out by four posts, each 60 feet in height, and painted bright red and blue in order to be clearly visible. Two sides of the course each measure 2.1 miles, while the two short lengths are just a fraction under a mile. The flying ground on which this special course is laid off will be entirely enclosed by a stout barricade having a circumference of over six miles, the spectators being massed behind the barricade, in which position they will be able to see perfectly, but will be unable to invade the ground reserved to the flyers.

It is expected that King Alphonso of Spain will be a spectator at the flights, a large house in the neighborhood of Rheims having been rented for his use during the month of August.

DAYTON HAS BIG WRIGHT CELEBRATION

Dayton, O., last week lionized the Wright Brothers, if such a term can be applied to those who imitate birds, and the nation and State had a very significant part in the celebration. But in interesting contrast to the wide enthusiasm exhibited by their home city, was the modesty of the two men whom it delighted Dayton to honor. Speeches have never been in the line of flying, but the whole world was startled by the fact that only four words were spoken by each on the first day of Dayton's jubilee, and on the next day when valuable medals were presented, Orville Wright said one sentence of seventeen words, and Wilbur spoke probably two minutes. Yet none the less were the honors heaped upon them. Thursday and Friday were set apart for the commemoration holidays for the city, and there were parades, dinners, a reception and a fireworks display to show the heartiness of the feeling, but at the same time the "Wright Aeroplane Factory" was working at nearly full force, perhaps the only one in the city doing so, and the two famous aviators spent several hours in it.

Triumphal arches spanned the main streets, American flags and bunting were everywhere in evidence, a martial air was instilled by the presence of national and State troops, and brass bands could be heard throughout the two days. On Thursday, at 9 o'clock every bell and whistle in the city blew for ten minutes, attracting the attention of the Wright Brothers, who were in their shops, so that they went out on the street in their shirt-sleeves to learn the cause of the commotion, and at 10 o'clock they were taken to the opening ceremony of the "Homecoming celebration." There was an item on the program from which something of interest was expected. It read "Responses by the Wrights," and there was something of wide interest therein, for each brother arose and said, "I thank you, gentlemen."

Nation, State and city paid tribute to the inventors on Friday when they were given the gold medals authorized by Congress from the United States, a diamond-studded medal bearing the official seal of the State of Ohio, and another from Dayton. Governor Harmon addressed the multitude for the Commonwealth; Gen. James Allen, Chief Signal Officer of the Army, for the Government, and Mayor E. E. Burkhart for the city. An international flavor was lent by the presence of Japanese Ambassador Baron Kogoro Takahira and Cuban Minister Carlos G. Velez. In answer to the speeches, Orville Wright said: "I wish our work was commensurate with the honors that have been heaped upon us. Thank you." Wilbur Wright found a happy topic and made a short, very short, speech. When the medals were given to the brothers they turned them over to Miss Katherine, the sister, who helped the boys in the earlier days of their work. Bishop Wright, the father, participated in the ceremonies.

The Wright aeroplane which will be used by Orville in the Government tests at Fort Meyer is already upon the scene. By June 28 it must pass the two tests in order to secure the $25,000 offered, one to fly five miles straightaway and return with a passenger, and the other to fly at least one hour with a passenger at a minimum rate of 36 miles per hour.

KIMBALL'S BIG AEROPLANE WRECKED

New York, June 21—So badly was the big eight-propeller aeroplane of Wilbur R. Kimball injured at the old Morris Park grounds by striking a bank near the south turn that it may not be repaired. Mr. Kimball was making a trial with the machine, and after running the biplane up and down the track to tune up the motor, he started to see if it would rise, but he was evidently so intent upon operating the engine that he did not notice a swerving of the aeroplane. At the beginning of the turn the end of the big plane struck the bank and crumpled like an egg shell, forcing the machine violently around, and overflowing gasoline caught fire but was extinguished. Both frames were badly cracked, and some of the propellers broken, the front and side wheels smashed, and the controlling system deranged.

Glenn H. Curtiss made two flights on last Friday, in one of which it is claimed that he attained a speed of 46.7 miles per hour in a distance of about of about a hundred yards. In another his speed was 26 miles an hour over a distance of 99 yards, in which he tried to go as slowly as permissible with maintaining equilibrium. The tests will be continued for some days.

How Dayton, Ohio, Was Bedecked During the Ceremonies of June 17-18, in Honor of the Homecoming of the Wright Brothers

IF WE ONLY HAD THE TIME

What is the matter with the American manufacturer? Five and more years ago an American invented, built, and partly perfected a slide valve engine. Laughed at and repulsed, he went abroad. There he received support and the new motor was still farther perfected, and later put on the market. With the latter step came the necessary publicity to bring it before the public, which resulted in some doubts as to its real ability. This having been proven beyond the hopes of the most sanguine friends, all of Europe devoted to automobiles has taken up the sliding valve idea. Many manufacturers are building under license to the American inventor, and as many more are at work on similar devices beyond the scope of the patent. While this has stirred up the subject of valves, much work is also being done on rotary valves and much investigation is being conducted to shed light on the complex subject of the introduction of the gaseous charge into the cylinder, and after combustion, its removal therefrom. In the meantime, the American manufacturers appear to plod contentedly along in the same old way, using the same old valves, and never giving a thought to finding anything different.

So, too, with spring wheels; in England and in France much experimentation is in progress, with the object of solving the combination problem of wheels and tires. These experiments may not have produced a perfect resilient wheel, the use of which would send all air-filled tires into oblivion, but at any rate they will result in some progress in this direction, and a more intelligent grasp of the subject.

In England, at present, there is going on a spirited discussion of the merits and demerits of front wheel brakes. This follows their adoption and use on a number of first-class cars. As this adoption and use is but the result of many months of construction and tests, it follows logically that the English manufacturers must have started work along these lines upwards of half a year ago, and possibly as long as a year ago. When we then admit that nothing is being done with the matter of front brakes on this side—whether these are good, bad, or indifferent—is it not equivalent to the admission that we are from a half year to a year behind the times? In so far as the goodness or badness of this particular device has never been publicly proven nor disproven, so that it is still but a matter of conjecture, we can in this case save ourselves and our self-respect by condemning it.

But in the long run that way will not always answer, for it is not possible to gain the front rank by crying down new devices as bad simply because their goodness has not yet been proven conclusively.

* * *

TWO SIDES TO EVERY QUESTION

In the course of a well-written editorial headed "Rules of the Road," the Buffalo *Express* sums up the situation with the following paragraph:

Let's keep the automobile in its place, but don't forget that there are other offenders, that there are other unenforced laws, besides those which apply to motor vehicles. Perhaps the world would be happier if it did not rush about so in devil wagons, but common sense can be applied even to this proposition. A class gets its reputation from its worst members, but the fact remains that there are good automobilists and bad and that the good far outnumber the bad. Let's have reasonable laws, applying to all classes, and let's have them enforced. Make an example of the fellow who blinds you with his car or causes it to emit unnecessary noises and smells, and look to the quiet, decent user of the automobile to applaud and sustain the effort.

Previous to its summation of the matter, the *Express* refers to the fact that it is undeniable that speed laws are violated; that some chauffeurs drive "as if the devil were after them—or sitting at their elbows;" that dripping-pans are emptied too often; that poor drivers use the "cut-out" too much, and that the use of acetylene lamps in city streets is abusive.

A great many automobilists do not so offend, states the *Express*, which then proceeds to tell of the unfair treatment to which the driver of the motor-driven vehicle is subjected in one way or another. Reference is made to the suburban trolley with its blazing headlights; the unillumined wagon and carriage of the horse-drawn variety, and the necessitated dodging of the careless cycler, though the absorbed pedestrian who walks across the road in a trance is forgotten.

Certainly it is gratifying these days to note the common-sense attitude of the enlightened daily press. Time was when the automobile came in for a more or less general denunciation in a majority of daily and weekly newspapers. Gradually, and now very perceptibly, with increase in numbers automobilists comprise all classes, where once they consisted principally of a select few of discerning enthusiasts who simply took to the motor-driven vehicle in advance of the others, and at the same time thus financially helped the makers through the period of experimentation.

WHY THE PARIS SALON HAS BEEN ABANDONED

PARIS, June 16—There will be no Automobile Salon in Paris this year, and for the first time since it was built the magnificent Grand Palais, in the Champs-Elysees, will remain empty and deserted during the months of November and December. For eleven successive years the Paris automobile show has been a feature, growing in size and influence until it was by far the most important industrial and social event that the city possessed. The Artists' Salon, the Horse Show and a few others occupied the same hall during a portion of each year, and succeeded in attracting no small amount of attention; but not one of them had the same amount of éclat as the automobile exhibition, and all combined did not arouse the same interest in all classes of the French public as the display of mechanically-driven vehicles.

In their desire to make it the most world-stunning exhibition of the year, the organizers of the Paris Salon have overshot the mark. Changes in automobile design having become less and less during the past four years, there was lessened necessity for an automobile exhibition. Added to this that the country had no longer any need to be converted to a mode of locomotion towards which it had been favorably inclined from the beginning; that the display was a most costly affair for the manufacturers; that the profits went to a body of men not directly engaged in the industry—all this considered, and it is not surprising that the annual Paris Salon has had to go by the board. It should be added that there will be another one in 1910, but it would be too much to say that it will be on the same lines as those of the past.

When the first purely automobile show—an offshoot of a cycle exhibition—was held in Paris in 1897 the Automobile Club of France undertook the lion's share of the responsibility and the labor. As the industry grew, three trade associations joined the club, and of recent years the annual exhibition has been organized by a special joint committee formed by the Automobile Club of France, which appointed its delegate, Gustave Rives, as general manager, and took 50 per cent. of the profits; the Chambre Syndicale de l'Automobile, allowed 20 per cent. of the profits; the Chambre Syndicale du Cycle et l'Automobile, also entitled to 20 per cent., and the Union of Cycle Manufacturers taking 10 per cent. of the profits. The tire manufacturers, some of whom had individually greater trading interests than the whole of the cycle makers combined, had no share in the show; while the important section of body builders—more important here than in other countries, owing to the separation of the industries—was also unrepresented on the organizing committee. The Automobile Club of France, more closely connected with the sporting than the business section of the automobile, was given an importance equal to that of the whole of the manufacturers, while the actual exhibitors had to pay in to them thousands of dollars in entrance fees and an equal sum in general expenses to maintain the high standard of the show. Naturally the club sought to continue this state of affairs, for the show allowed it to net the respectable sum of about $10,000 per annum.

The first to break away was the Chambre Syndicale du Cycle et de l'Automobile, which drove out its pro-Salon committee, put M. Darracq at its head and voted unanimously against a show next year. The Automobile Club of France and the Cycle Manufacturers took up the opposite position, while the Chambre Syndicale de l'Automobile, which is very closely connected with the club, having its offices in the same building, appeared to hesitate. The Marquis de Dion, president of the Chambre, was strongly in favor of a show, and although his committee a few weeks ago voted for abandonment, the vote had to be ratified by a full meeting of the members. The battle took place this week, and after several hours' fierce fighting the anti-show group got the upper hand, the vote being 79 against the holding of a show, 28 in its favor, and 3 blank papers. In face of such a vote it is, of course, impossible for the club to think of throwing open the doors of the Grand Palais this year. The manufacturers voted on principle in favor of a show in 1910, but nothing was decided as to the bases on which it will be held. There is every possibility that the old conditions will be changed and that the manufacturers' share in the profits will be very much larger than it has been in the past. The system, too, of allotting the best positions to the oldest established French firms, or those having been most successful in speed tests will also be swept away, the result of such a system being to give to the early firms an importance in the eyes of the public which they have, industrially speaking, in many cases long ceased to occupy. The manufacturers are, for the most part, in favor of drawing of lots for the whole of the show spaces, or in lieu of that of admitting all firms producing a certain number of cars per annum to draw for positions in the center of the hall, irrespective of nationality or date of origin. Either one of these propositions seems equally fair to all concerned.

ONE-LUNGER WINS FRENCH VOITURETTE RACE AT BOULOGNE

BOULOGNE SUR MER, June 20—Giuppone, driving a single-cylinder Lion-Peugeot, to-day won the fifth annual race of the Coupe des Voiturettes, held on the Boulogne circuit, covering the 282.5 miles in five hours and 56 minutes, averaging a speed of 47.5 miles per hour. Goux, in a car of the same make with two cylinders, finished second, while Thomas, in a single-cylinder Le Gui, was third. Boillot, in another one-cylinder Lion-Peugeot, was fourth, this firm thereby making the best team performance. Pilliverde, Zuccarelli, and Derny, each driving four-cylinder Hispano-Suiza cars, took fifth, sixth, and seventh positions, a remarkably good display. Two English Calthorpe machines, of four cylinders, driven by Porter and Burgess, respectively, finished eighth and ninth. There were twenty-one starters and eleven were eliminated through mechanical defects during the course of the event.

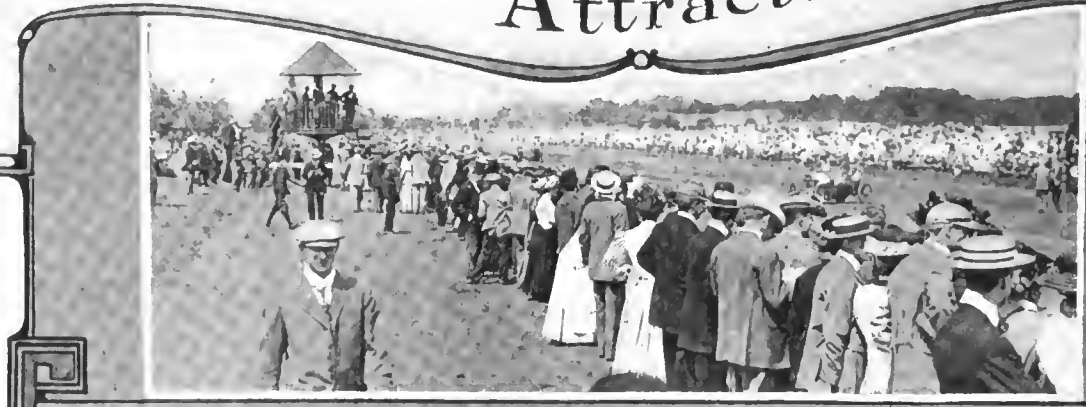
A heavy fog necessitated an hour delay in the morning at the start, and even when the machines were sent away, in France's only speed contest of the year, the drivers could see but about 500 yards. Later the mist lifted and magnificent weather prevailed. The only mishap of the day was the overturning of Farcy's single-cylinder Crespelle machine, which took fire and was almost entirely destroyed. There were twelve rounds to be covered and after the first three were completed the interest centered in the competition between the Lion-Peugeot and the Hispano-Suiza, the former of which was the faster make, and after half the race was completed, there was no doubt of the finish, barring accidents.

A method of treating the course with calcium chloride, instead of oil, was the greatest success, there being no dust, and none of the participants stopped to have their eyes treated.

OPEL WINS PRINCE HENRY TOUR

BERLIN, June 17—Germany's premier touring contest, the Prince Henry competition, was won by Wilhelm Opel in an Opel car, with Willie Poege second in a Mercedes. Of these two makes in the event there were 16 Opels and 8 Mercedes. The course was 1,132 miles in length.

Readville's Meet still Attracts Thousands



The Crowd That Lined Readville's Historic Course, on Bunker Hill Day, to Witness the Auto Races

BOSTON, June 21—Bay State Automobile Association and Readville track have long had reputations as the sponsor and site of some of the best automobile track race meetings in the country, but all previous successes were eclipsed on Thursday. A new world's record of 23:35 for twenty-five miles by DePalma; a new record for the track of 54 seconds by the same driver; almost total absence of tedious delays and accidents, races won by a wheel, and keen competition all the way through, were some of the features that entertained the large crowd for four hours and sent them home well satisfied. Even tire trouble did not interfere materially with the races, the absence of punctures being remarkable, considering the high speed that was made in almost every one of the eight events on the program. The weather was ideal and the number of automobiles along the home-stretch and within the track was very large. The races were under the able management of Chester I. Campbell, manager of Boston's automobile shows, and his associates on the committee were V. A. Charles, C. J. Bailey, Frank E. Wing, W. C. Schmunk and James Fortescue.

DePalma was easily the star of the meet. Next to DePalma the honors went to Lorimer with the Chalmers-Detroit, who gave the former a long and hard tussle in the Harvard trophy race, making him push his car to the limit, and he captured the second most important event, the contest at ten miles for the Automobile Trade trophy.

The Harvard trophy event was a free-for-all, the winner taking the magnificent trophy and $500 in cash, second car winning $200, and third car $100. It was run in two preliminary heats at five miles and a final at twenty-five miles. In the final the cars were the Fiat, Chalmers, Detroit, Alco, Renault, and Allen-Kingston. DePalma got the lead at the start and was never headed. The first mile the Alco was second and then it was passed by the Chalmers. At the end of five miles it had developed into two contests, the Fiat and Chalmers-Detroit fighting for first place and the Alco and Renault having it out for third position. At ten miles the first two cars, racing close together, were a quarter mile ahead of the second two, with the Allen-Kingston nearly a lap behind. At fifteen miles the Fiat led by an eighth of a mile over the Chalmers and by a half mile over the Alco, three-quarters over the Renault and more than a lap over the Allen-Kingston. The positions remained about the same until the twentieth mile, when the Alco had tire trouble and dropped into fourth place, the Renault going up into second. Then began some of the finest driving ever seen at Readville. Closely pursued by Lorimer, DePalma let out to the last notch and whirled around the track scarcely raising the dust, so neatly did he take the corners. In the twentieth mile he lapped the Alco and in the twenty-fourth the Chalmers. His time was 23:25 and he was given a rousing reception by the crowd when he came back to the stand and it had been announced that a new world's record had just been made.

In the Automobile Trade trophy race at ten miles for stripped stock cars chassis over 36-horsepower there were seven entries and all came to the tape. They were two Allen-Kingstons driven by Glenworth and Hughes, Knox driven by Basle, Welch driven by S. L. Rogers, Alco driven by Grant, Stoddard-Dayton driven by B. W. Shaw and Chalmers-Detroit driven by Lorimer. The first eight miles were a duel between the Chalmers-Detroit and the Alco, the Alco leading for the first mile and then the Chalmers going to the fore. In the ninth mile, however, the Alco had trouble and the Stoddard-Dayton went up to contest with the Chalmers-Detroit for supremacy. Lorimer, however, had the race well in hand and won in 9:46 1-5, by about five-eighths of a mile over the Stoddard-Dayton. The Allen-Kingston driven by Hughes was third, the other Allen-Kingston fourth, and the Welch fifth.

By all odds the most exciting finish of the day was in the five mile-race for roadsters and runabouts of 31-horsepower and over, for the Knowles cup. There were two preliminary heats and a final. The Allen-Kingston, driven by Glenworth, won the first heat in 5:17, with the American Roadster, driven by A. J. Andrews, second; and the Chalmers-Detroit, driven by F. F. Cameron, third. In the second heat Hughes's Allen-Kingston dropped out, and the other two cars were stopped at the end of the third mile, both qualifying for the final. In the final were the Stoddard-Dayton, Allen-Kingston, Chalmers-Detroit and Welch. The Stoddard-Dayton cut out the pace for four miles, having a good lead with the other three bunched. Then it had trouble and the others closed up and the final mile was as pretty a contest as is often seen at an automobile meet. Coming into the head of the stretch to the tape all the cars were bunched like a lot of running horses. Here Rogers showed the reserve power in his Welch and letting it out a notch shot to the front and went under the wire a matter of a few feet ahead of the Allen-Kingston, with the Chalmers a close third and the Stoddard-Dayton fourth. The time was 5:16.

The races opened with the amateur event of five miles with four starters, the Welch driven by A. W. Merriam, Chalmers-Detroit driven by C. S. Hall, Buick driven by Ryall, and Stoddard-Dayton driven by Shaw. The Stoddard-Dayton won in 5:21, with about a quarter mile to the good over the Welch.

DePalma's mile trials and his match with Basle followed, and then Harry Grant with the Alco, and Hugh Hughes with the Allen-Kingston were sent five miles in a match, Grant winning in 5:6 1-5. It was a close race all the way. A five-mile race for touring cars was awarded to the Midland, which was the only touring car that started, the Jackson which made the distance in 6.04 3-5 being declared a runabout and the Buick dropping out. The three-mile race for roadsters and runabouts up to 30-horsepower had three starters, a Columbia driven by J. J. Coffey, a Chalmers-Detroit Thirty, driven by F. F. Cameron, and a Buick driven by James B. Ryall. The Buick was early out of the going and the Columbia had little trouble in winning over the Chalmers-Detroit in 3:38 with a quarter mile to the good. The only accidents of the day were minor in character, two racing cars catching fire apparently from back-firing. These incidents caused some excitement but little damage. The summary:

5 MILES FOR BAILEY TROPHY, AMATEUR DRIVERS

	Car	H.P.	Driver	Time
1	Stoddard-Dayton ...	60	B. W. Shaw.....	5:21
2	Welch	70	A. W. Merriam....	
3	Buick	30	J. B. Ryall.....	

SPECIAL TRIALS TO BEAT TRACK RECORD OF :54 2-5

1	Fiat		R. DePalma	:54 1-5 & :54

25 MILES FOR HARVARD TROPHY, OPEN TO ALL

First Prize Trophy, and $500; Second Prize, $200; Third Prize, $100

First Heat at 5 Miles:

1	Fiat	60	R. DePalma	4:54 4-5
2	Chalmers-Detroit ...	40	L. B. Lorimer.....	
3	Alco	60	H. F. Grant.....	

Second Heat at 5 Miles:

1	Stoddard-Dayton ...	60	B. W. Shaw.....	5:6 3-5
2	Allen Kingston.....	48	C. A. Glenworth...	
3	Renault	60	C. Basle	

Final Heat, 25 Miles:

1	Fiat	60	R. DePalma.....	*23:35
2	Chalmers-Detroit ...	40	L. B. Lorimer.....	
3	Renault	60	C. Basle	

*New world's record.

5 MILES SPECIAL MATCH RACE

1	Alco	60	H. F. Grant.....	5:6 1-5
2	Allen Kingston	48	H. Hughes	

5 MILES FOR TOURING CARS UP TO AND INCLUDING 36-H.P.

1	Midland		Jackson	6:4 3-5

(Disqualified for not having equipment according to specifications; protested).

10 MILES FOR AUTOMOBILE TRADE TROPHY FOR STRIPPED STOCK CAR CHASSIS OVER 36-HORSEPOWER

1	Chalmers-Detroit ...	40	L. B. Lorimer.....	9:46 1-5
2	Stoddard-Dayton ...	60	B. W. Shaw.....	
3	Allen-Kingston	48	C. A. Glenworth...	

3 MILES FOR STOCK ROADSTERS UP TO 30-HORSEPOWER FOR THOMAS TAXICAB TROPHY

1	Columbia	24-30	J. J. Coffey.....	3:38
2	Chalmers-Detroit ...	24-30	F. F. Cameron.....	

5 MILES FOR ROADSTERS AND RUNABOUTS, 31-HORSEPOWER AND OVER, KNOWLES CUP

First Heat:

1	Allen-Kingston	48	C. A. Glenworth...	5:17
2	American	50	A. J. Andrews.....	
3	Chalmers-Detroit ...	40	F. F. Cameron.....	

Second Heat:

1	Stoddard-Dayton ...	60	B. W. Shaw.....	None taken.
2	Welch	70	S. L. Rogers.....	

Final Heat:

1	Welsh	70	S. L. Rogers.....	5:16
2	Allen-Kingston	48	C. A. Glenworth...	
3	Chalmers-Detroit ...	40	F. F. Cameron.....	

25 MILES SPECIAL MATCH

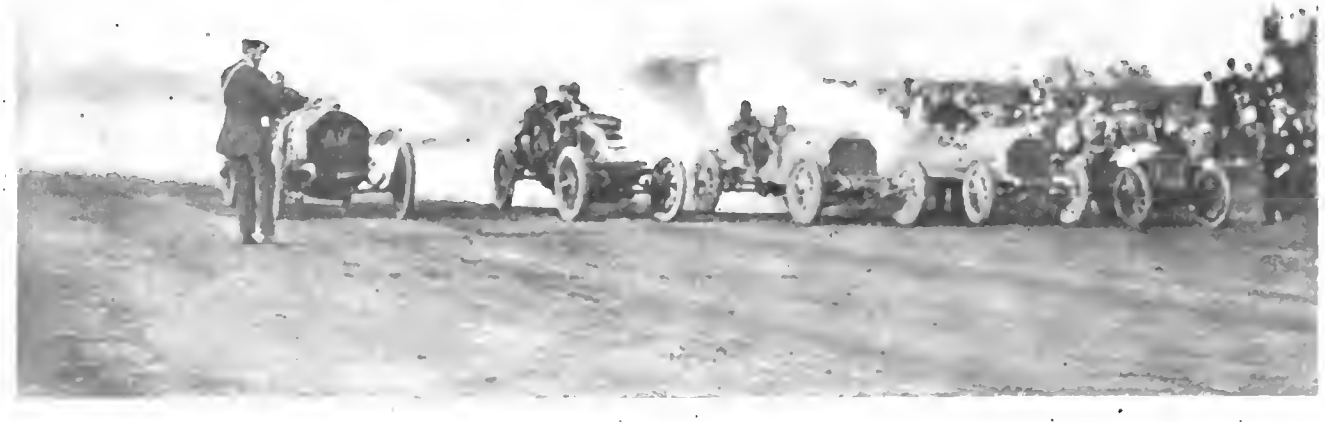
1	Fiat	60	R. DePalma	24:39 2-5
2	Renault	60	C. Basle	

SHERMAN SETS TIME FOR CAPITAL RUN

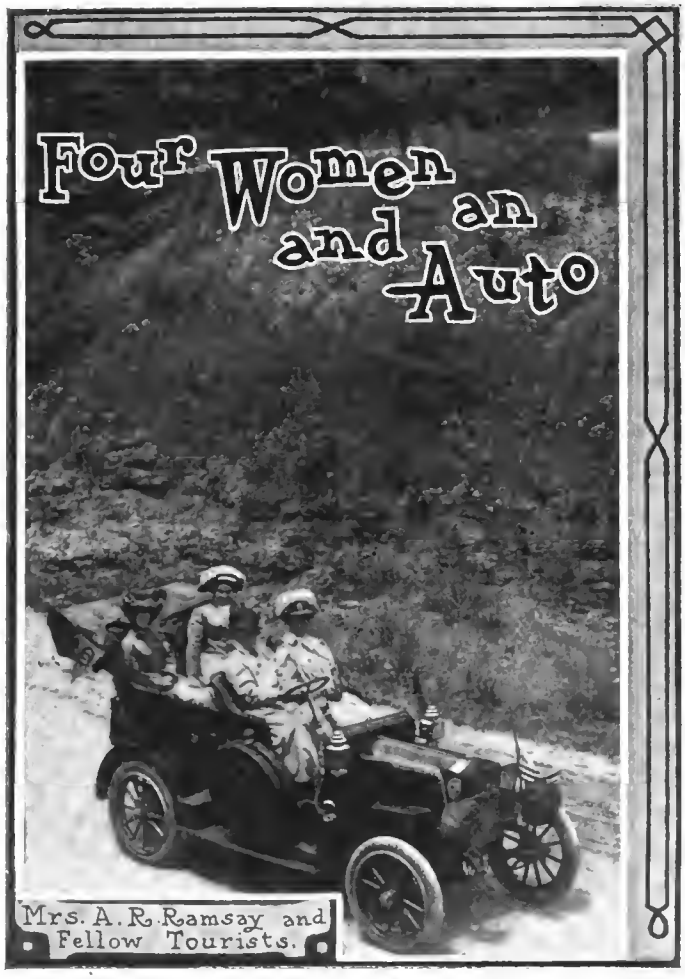
WASHINGTON, D. C., June 21—With the Vice-President of the United States to set the secret official time, the automobilists of this city yesterday participated in a sociability run to Great Falls, a distance of 16.3 miles. The affair was promoted by the Washington *Times*, and was designed to show that automobiles could be driven over the conduit road (one of the most tempting stretches of road in this country) without the drivers becoming imbued with the racing mania. In this respect, as in all others, the run was a pronounced success, and proved to be the greatest automobile event ever given here. In setting the time, which remained sealed until after the contestants returned to the starting point, Vice-President Sherman said he was well aware that the run could be made in very much less time than he fixed. He went on to say that he fixed the time on the theory of encouraging, rather than discouraging compliance with the law. Upon this theory he thought the run ought to be made in 54:07.

There were 74 contestants in the run. Curiously enough it remained for a Thomas taxicab, driven by H. M. Miller, a public chauffeur, to nearest approach the secret time. He covered the 16.3 miles in 54:13 4-5, just 06 4-5 behind the official time. A Baker electric, driven by John Bartrem, won second place, his time being 54:24 2-5. R. P. Andrews, in a Chalmers-Detroit, was third, the time being 53:48, while another Baker, piloted by G. A. Weaver, won fourth prize. His time was 54:28. Miss Lillian Miller, a sixteen-year-old girl, captured the fifth prize in a Ford, her time being 54:38 3-5. There were twenty-one prizes in all.

The weather conditions were ideal, and the run attracted much attention, thousands of people being at the starting point. They returned five hours later to hear the returns read, and kept a big detail of police busy holding them in check.



Start of the 25-Mile Free-for-All, at Readville Track, In Which DePalma Drove a Record Victory



CHICAGO, June 21—'We have had a most enjoyable time so far," said Mrs. Alice R. Ramsey, when she and her party arrived in Chicago en route for San Francisco in a Maxwell car. "So far it has been perfectly lovely and we feel certain that the remainder of the trip will be equally so. Excepting for the first two days of the trip, when it rained hard and the roads were muddy, the trip has been almost without incident, and we have simply sailed along as fast or as slow as we pleased, enjoying the beautiful scenery which, by the way, we expect will be even more beautiful as we go west."

When Mrs. Ramsey left New York, June 9, on the first transcontinental trip ever attempted by four women, in her Maxwell touring car, she was given a right royal sendoff, and this has been continued in each city where a night stop was made. Buffalo was reached on Saturday, and the tourists remained there until Tuesday on account of the reception accorded them and the many requests to do so. On that day they traveled to Erie, reached Cleveland on Wednesday, Toledo Thursday, South Bend Friday, and Chicago on Saturday.

Many have been asked why the women are taking this long trip. This can best be answered by the fact that Mrs. Ramsey is an ardent automobile enthusiast, who believes in the driving of cars by women just as much as by men. As proof of the ease with which women can handle a car, make all necessary road repairs and such, Mrs. Ramsey decided to spend a vacation on a long tour, and in a way blaze the way across the American continent for other fair motorists. This is the real reason for the trip, which no woman has ever before attempted without a man at the wheel. And, too, there is other reason for it; her desire to see properly the beautiful Western country in the proper way. On the trip she is driving the same Maxwell car in which she has competed with great success in a number of endurance runs in New York and Philadelphia. Her knowledge of the car is most thorough and capable.

LOGICAL PLEA FOR AUTOMOBILE SANITY

By CHARLES CLIFTON, President, A. L. A. M.

Automobile owners, as a rule, in discussing their costs generally name the great item of expense as being tires, and in that connection they are quite inclined to arraign the makers of pneumatic tires as being responsible for this condition. These statements are an individual expression of opinion based on more or less experience, and doubtless justified in part by the records of bills paid.

These remarks in the same sense are an individual expression of opinion based upon the same facts and are contributed in the hope that they may suggest a way of reducing the sum total of tire bills, as well as leading in the direction of safer and saner methods in driving, and, in the last analysis, greater pleasure from motor cars.

There are three prime factors responsible for short tire life. First, excessive speed, especially during the warm months. Second, changes of direction at a high rate of speed; and third, excessive and unnecessary use of mechanical brakes. My experience has gone to prove that—punctures excepted—the life of tires is enormously prolonged by avoiding the above three cardinal enemies of the pneumatic tire.

So much for the direct money cost, but if these three cardinal principles are insisted upon by owners, the liability of accident will be reduced to a minimum, and all the high costs incident to property and personal damage. Accidents will also be reduced, as well as wear and tear mentally on an owner in connection therewith. In other words, sanity in the use of the motor car is an incalculable money value which no owner should ignore; and the reverse of the proposition is an unnecessary extravagance, which if indulged in should not carry with it an invective against the tire manufacturer or the manufacturer of the motor car. In other words, the responsibility for high costs in running expenses is absolutely in the hands of the owner, or perhaps more directly in the hands of the driver. Excessive speed under all conditions is done at high cost which can only be reduced by the adoption of sane methods.

To go a step further in this line of reasoning, I wish to plead for saneness in the use of highways. Not only in the matter of excessive speed, but also in the relation which should subsist between those who ride in cars and those who use it in other and older ways. The antagonism of the farmer against the automobile is mainly the result of a series of circumstances which to "the other fellow" seems like a succession of outrages. It is well for the driver of a motor car to realize that the other fellow used the highway, more or less unmolested, ever since there were highways. That while he may feel he has pre-emption, that pre-emption goes no further than the joint use. For the driver of a motor car to assume to use more than his share of the road, to make of his vehicle a menace, or at the very least a nuisance to other users, is a very natural cause for antagonism. The users and drivers of motor cars can, by sane driving, do the larger part in accomplishing a reversal of this sentiment, and in any event only fair play will eliminate the present friction.

NO RACE TO BE HELD AT DIEPPE

PARIS, June 16—The project to hold an open speed test on the Dieppe course, with Victor Breyer as manager, has been abandoned in view of the disinclination of the authorities to grant permission. Although the proposed race was in no way connected with the Automobile Club of France, and was intended more for private owners of racing cars than for manufacturers, the promotors were made to understand that a petition to hold the race would not be favorably received unless it came through the club. Naturally the racing board of the club did not look with any favor on the intruder and the project had to be abandoned. It is declared that the club promised to hold an international race itself next year on the Dieppe course, but no official confirmation of this is available. If a race is held at Dieppe the Angers district will have just cause for protest.

CARRIS BEST IN PENNSYLVANIA ENDURANCE RUN

By GEORGE M. SCHELL.

PHILADELPHIA, June 19—After one of the most gruelling contests of the year, the State Highway Endurance contest of the Quaker City Motor Club, from this city to Pittsburg and return—750.5 miles—came to a conclusion last evening with the veteran Franklin-Carris combination a long-margin winner in Class A (touring cars over $2,000); the 45 horsepower Haynes, driven by Walter E. Shuttleworth, annexing the Class C trophy for runabouts over $2,000, and Walter Cram, in his Mitchell "20," capturing the Class D cup for runabouts listed at $2,000 or less.

A series of rains during the preceding fortnight had rendered all but the comparatively few-and-far-between stretches of State highway met with on the route nearly untravelable in many places, especially through the mountains, and fully 40 per cent. of the route may be included in this category. The road conditions were frightful. Soft, adhesive mud and ruts—the latter in some places 15 inches deep—formed the roadbed in these sections, and the strain put upon the cars by the continual grind, and the subsequent speeding in an effort to make up lost time, told heavily in the penalty column. That the small, but select entry list should have stood the continued pounding as long as they did is little short of wonderful. As it was, the two cars that fell by the wayside—the Elmore and the Palmer & Singer, both in Class A—had finished four-fifths of the journey, and that the hardest part before they succumbed. In the case of the Elmore, which had been clean score all along, it took an accident to eliminate it—a contrary countrymen refusing to give young Hardart, its driver, sufficient room to get past, the taking of a long chance resulting in the tearing loose of the car's rear construction by a skid into a roadside culvert heading. Broken springs in a section far removed from a repair shop so delayed the Palmer & Singer on the last day that it was withdrawn. Nearly all troubles were caused by terrible roads.

The strenuous experiences of the Haynes crew began on the first day and continued through to the end. As related in last week's issue, a broken axle 75 miles out from Williamsport, the night stop, cost the car over 12 hours time penalty, and the second days' start was made with but an hour's interval for breakfast and supplies. Shuttleworth, although nearly exhausted, managed to get into Johnstown with but 15 minutes' time penalty registered against him, due almost entirely to his unwillingness to take chances with the light axle that had been sent him from New York to replace the broken part.

Coming out of Johnstown, Wednesday morning, Shuttleworth took to the sidewalk to avoid collision with a trolley car at the entrance to the bridge over the Conemaugh, and was not only dragged before a magistrate and fined (the fine was later remitted) but so weakened his right front wheel that it collapsed at Armagh, ten miles farther on. It looked so much like a "down-and-out" proposition that Observer Skinner abandoned the outfit and went to Pittsburg in a Pullman (P. R. R.). But Shuttleworth and Rose, his mechanician, were not to be denied; they found a blacksmith, who, under their instructions, fashioned spokes out of rough hardwood with a saw, hatchet and shave-knife, and in eight hours had put a new wheel together. At 1 o'clock they were en route, and ran into the Smoky City while the rest were eating breakfast. They snatched three hours' sleep and started after the others, reaching Lewistown in a downpour at midnight, having lost the road several times because all of the confetti had been washed away. Even the last day was not without its mishap. Getting away from Lewistown about half an hour behind the bunch, the narrows below that town took an hour and a half to negotiate, so bad was the road. The rough going developed a six-inch wabble in the front wheel, and Shuttleworth and Rose spent nearly an hour filing the axle in order to take up the play. Everything then went well until Downingtown was reached, when, in attempting to change seats with Observer Schell, Shuttleworth fell from the car and was knocked senseless, suffering besides several cuts and bruises. He was fixed up at the country home of Mr. Hardart (entrant of the Elmore which had gone out the previous day), a few miles farther on, and reached Philadelphia about two hours late. The Haynes crew were the happiest in the bunch, and were congratulated on all sides for their plucky performance. They consider the Class C cup, which they won by virtue of being the only entrant, a sufficient recompense.

The Palmer & Singer troubles were almost entirely due to spring trouble, which began the first day and persisted to the end, finally causing the withdrawal of the car at Harrisburg. This is the same car and driver—William Wallace, Jr.—that made such a good showing in the Fairmount Park 200-mile stock chassis race last October. Ten miles outside of Pittsburg, Wallace discovered that the steering post was broken. They were just approaching a hairpin turn leading down the steep hill into Wilmerding, but Wallace discovered the defect in time to jam on the emergency and stop the car just at the turn. An instant's hesitation on his part and the whole outfit would have shot over the fifty-foot declivity. The car was finally worked down to the foot of the hill, where, after a wait of three hours for help from the Smoky City, Wallace and Ralph, his mechanician, became tired of the delay and rigged up a "first aid" substitute steering device, which got them into town at about 4 o'clock, nearly five hours late. Sitting astride the hood, Ralph pushed on the reach rod, and Wallace, by means of a piece of clothesline attached to the front axle and with a screw driver for a handle, guided the car the remaining ten miles to the Banker Brothers garage. Next morning they put in a new steering-post, and were delayed so long that the heavy rain, which began about midday, took out a small bridge over a run,

which had been passed by the others hours before. In half an hour, with the aid of lumber from a nearby farmyard, they built a substitute bridge, and reported at Lewistown about 8 o'clock, only to be finally eliminated on the last day by inability to replace their broken springs. They finally limped into Harrisburg about sundown, too late to push on to the finish.

Young Frank Hardart, Jr., the only amateur driver in the run, had the sympathy of all hands when his car was rendered hors de combat only eight miles from the fourth day's control by an accident. The Elmore, which had an absolutely clean road score up to the point where the accident occurred, was well ahead of its schedule and was bowling along the good State road, which extended all the way to Lewistown, when, in attempting to pass a team whose driver refused to give him half the road, the rear of the car swung into one of the concrete culvert headings which line the road and tore the rear springs loose from the axle and damaged the right rear wheel. It was beyond the ability of Hardart and his younger brother, who acted as his mechanician, to fix up the car in order to reach Lewistown, and it was dragged into a nearby barn. A passing auto carried the party into night control, and they left for home on the 8 o'clock train, a sadly disappointed party.

Carris, as usual, failed to get into the limelight. He is so careful and conservative, and withal so speedy when the conditions favor, that he had not a particle of trouble on the road. The Franklin came into Philadelphia without a mark on the observer's cards for the whole five days, and although the technical committee's examination developed 21.2 points penalties against the Franklin, that total is decidedly small when the conditions of the strenuous 750-mile journey are taken into consideration. On the fourth day, in the midst of a driving downpour, Carris ran past a turn, it being absolutely impossible for his younger brother, who was keeping tabs on the "dope book" to see the print. Four miles farther on he discovered his mistake and ran back. It was then that the usually conservative Carris took a chance and "beat it" to such purpose that he made up his lost time and pulled into Lewistown a few minutes ahead of schedule. Even this racking had no deleterious effect.

Cram's experience with his Mitchell was almost identical with that of Carris, and apart from a 3.2 penalty for replacing a defective spark-plug, his road work was faultless. Naturally, the heavy going told more heavily against his little Mitchell than against the big Franklin, but he had to punish his car to reach the night control on almost every leg of the journey.

There was no press car on the run, THE AUTOMOBILE representative securing an observer's appointment in order to keep tabs on the doings. It was a coincidence that on the only days that the Haynes reached a night control before sundown, THE AUTOMOBILE man occupied the observer's seat.

Pilot and acting referee "Doc" Overpeck did the bulk of the driving on the pilot car, Norman Stadiger's Chalmers-Detroit, and with the exception of the first day, when a troublesome clutch delayed the "spaghetti" car so persistently that Overpeck had to transfer his flag to one of the contesting machines, the Chalmers-Detroit performed splendidly throughout the run.

The Quaker City Motor Club carried out the run with the same attention to detail as if there had been thirty instead of five cars on the road, and the loss of upward of $1,000 was borne without a murmur. Lack of cars was the only trouble.

The following schedule shows the distances, times and running schedule for each of the five days of the run. On only one day, Wednesday, was it found advisable to adhere to the previously decided upon 20 miles an hour running time. On all of the other days the 18-mile schedule prevailed.

Day	Route	Running Schedule M. P. H.	Dist.	Total Dist.	Running Time
Monday	Philadelphia to Williamsport	18	191.2 1-2	191.2 1-2	10:39
Tuesday	Williamsport to Johnstown	18	146.2 1-2	337.5	8:08
Wednesday	Johnstown to Pittsburg.	20	74.7	412.2	3:45
Thursday	Pittsburg to Lewistown..	18	170.9	583.1	9.36
Friday	Lewistown to Philadelphia.	18	167.4	750.5	9.20

CLASS A, TOURING CARS OVER $2,000

No.	Car	H.P.	Driver	Time	Penalties Work	Tech.	Total
18	Franklin	42	C. S. Carris...	0	0	21.2	21.2
5	Elmore	85	F. Hardart, Jr.	out	4th day	——	1000.

CLASS C, RUNABOUTS OVER $2,000

4	Haynes	45	Shuttleworth..	2543	115.2	67.	2725.2

CLASS D, RUNABOUTS, $2,000 OR LESS

6	Mitchell	20	Cram	0	3.2	342.9	346.1

DETAILS OF TECHNICAL PENALTIES

Franklin—Loose grease cup, 2; loose muffler, 5; 2 lost body bolts, 1.2; loose body bolt, 1; 6 loose chassis bolts, 1.2; 5 loose push rod bearings, 2.5; loose boot on driving shaft, .2; broken brake support, 3; loose steering connection, 15—total 21.2.

Haynes—Leaky radiator, 3; 2 broken spring leaves, 6; loose spring clip, .2; 2 broken chassis bolts, 2; 2 loose chassis bolts, .4; bent axle, 25; 2 missing screws from commutator shaft, .4; 2 loose steering connections, 30—total, 67.

Mitchell—Broken oil lead, 5.2; loose radiator,3; 3 leaky wster connections, 3; broken spring leaf, 3; broken spring clip, 2; loose muffler, .5; lost body bolt, .6; 9 broken chassis bolts, 9; 6 loose chassis bolts, 1.2; 2 leaky gasoline pet cock connections, .2; leak in gasoline tank, 10; 4 broken and worn-out bearings on front wheels, 200; loose cross member frame, 50; loose dash steering housing and broken bracket, 25; loose ignition connection, .3; 2 loose steering connections, 30—total, 342.9.

Elmore and Palmer & Singer not examined by technical committee.

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

Aug. 5-7.....Chicago, Midsummer Meeting Society of Automobile Engineers.

Nov. 6-13.....Atlanta, Ga., Auditorium-Armory, National Automobile Show.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Decennial International Automobile Show: American Motor Car Manufacturers' Association, with Importers Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.....New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Feb. 5-12.....Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

June 21-26.....Binghamton, N. Y., Fourth Annual Endurance Run, Binghamton Automobile Club.

June 22-28.....Albany, N. Y., Fifth Annual Tour, Bretton Woods, Portsmouth, Boston, Albany Automobile Club.

June 24-26.....Montreal, Blue Bonnets Track, Race Meet. R. M. Jaffray, Manager.

June 25-26.....Philadelphia, 24-Hour Track Race, Quaker City Motor Club.

June 26.....Cincinnati, O., Hill Climb, Cincinnati Automobile Club.

July 3 and 5.....Wildwood, N. J., Straightaway Races, Motor Club of Wildwood.

July 4.....Los Angeles, Cal., Southern California Automobile Dealers' Association. Road races, 250 Miles for Large Cars; 150 Miles for Light Cars.

July 12.....Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.

Aug. 5.....Chicago, Fourth Annual Algonquin Hill Climb, Chicago Motor Club.

Sept. 6-11.....Lowell, Mass., Automobile Carnival, Lowell Automobile Club.

Sept. 15.....Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.

Oct. 7.....Philadelphia, Second Annual Stock Chassis, 200-mile Race, Fairmount Park, Quaker City, M. C.

Dec. 29-30.....Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

LONG ISLAND HAS A MOTOR HUNT

Manager Pardington Instructs a Contestant.

NEW YORK, June 21—Most unique in its idea and more or less aimless in its procedure was the "motor hunt" held on Thursday in connection with the celebration of the opening of the Queensboro bridge. For an entire day, twelve hours, about twenty-five automobiles scurried around the western end of Long Island in a search for blind controls where they might secure marks entitling them to some really valuable prizes. The plan of the event called for a hunt for these stations and for a "quarry" car, and the autoist whose card was punched the greatest number of times at the former, or who met the latter most often, was to be declared the winner. There was a tie. Charles W. Landers, in a Chalmers-Detroit Thirty, and William Allen Kissam, in a six-cylinder Ford, were deadlocked when the cars were examined in the evening, and in addition Mr. Landers won quarry prize by meeting the elusive auto the largest number of times. Mrs. J. N. Cuneo was one of the contestants and will probably get third or fourth place. Some method will be arranged by which the tie for the two trophies, both bronze statues, one valued at $250 and the other at $100, will be decided.

The interest among the participants was such that the machines were kept at work throughout the dozen hours, hunting up real estate offices, hotels, and other certain places, such as garages, where it had been announced the controls would be found, and indicated by a flag. Secrecy had been maintained successfully as to the location of the stations so that little or no hold could be secured by the contestants, and the quarry car kept so well away from the others that the score of the winner, even, was low.

At an "Automobile Blue Book" Station in Jamaica.

Krug's Corner, Famed in Vanderbilt Race Lore.

One of the Blind Checking Stations.

THAT BRIARCLIFF RACE ROAD DEPOSIT

NEW YORK, June 21—An interesting echo of the Briarcliff race has been heard in the decision of Justice Truax, of the Supreme Court, in regard to the money paid to State Engineer Skene, for possible damage to the roads in Westchester county over which the contest was held. Two days before the race, which was run on April 24, 1908, the State official demanded $4,600, as a guarantee against possible injury to the highways and expense to the State of repairing them, threatening to stop the race unless the money was paid. According to the Court, Skene had no legal right to make this demand and therefore must return the full amount, instead of but $582.14, thus bringing up the case. Robert Lee Morrell, the plantiff, had paid the money to Skene.

The decision is based upon the State laws which allow any locality to give over its road for a special race, imposing such conditions as are necessary, but in the case of the Briarcliff there were no conditions made by the officials who gave the permission. There is nothing in the automobile law which makes it necessary to obtain the consent of the State engineer, and the only law under which the latter could have acted is that providing for the improvement and protection of highways, for the disobedience of which a fine of not less than $10, nor more than $100 may be imposed. Therefore it was decided that Engineer Skene might have sued for the penalty, but not the damages. Inasmuch as he had no power to recover the amount of the damages, he had no authority to exact a deposit.

COMPLETING PLANS FOR GLIDDEN TOUR

DETROIT, June 21—There will be "something doing" every minute, from the time the first of the Glidden entrants reaches Detroit until the last car has started out Michigan Avenue on the journey which will end at Kansas City some three weeks later. Local committees having the entertainment of tourists and visitors in charge are planning doings that will leave pleasant memories in the minds of all, for all time, and nothing will be left undone to make those who visit Detroit realize that the hub of the automobile world fully appreciates what such an event as the Glidden tour means. Quick to grasp the import of the occasion, the city, at the suggestion of Mayor Breitmeyer, donated a beautiful trophy, to be awarded the successful contestant in the baby tonneau class, thereby adding to the interest of the event. It has also been officially decreed that motorists will own Detroit from the moment the first of the tourists arrive until it is all over. "Glidden Tour Days" is the title bestowed on

Trophy for Runabouts Offered by Chairman Hower

July 9 to 12 by the local committee appointed by the Detroit Automobile Dealers' Association to arrange for the entertainment of A. A. A. officials, entrants, automobile manufacturers, and others who will be here during that period, and "rare old Glidden tour days" they will be.

Friday evening, July 9, will witness the formal opening of festivities with a banquet for A. A. A. officials and newspapermen, at which Mayor Breitmeyer will turn the keys of the city over to Chairman T. B. Hower, of the committee. Saturday morning the visitors will inspect the local auto plants, starting from the Hotel Pontchartrain. Automobiles will be provided for all and a new understanding of Detroit's position in the industry is bound to follow. Saturday afternoon comes the automobile parade, the big feature of the three days' celebration, which promises to be one of the greatest ever. Not only Detroit motorists, but those from surrounding towns will participate, and prizes will be awarded for the best decorated machines in four divisions—gasoline, electric, commercial, and motorcycle. The parade will start downtown and end at Belle Isle, where there will be an athletic carnival participated in by employes of local automobile factories, with a long list of prizes.

Sunday morning the visitors will board the City of Cleveland, the finest sidewheel passenger steamer in the world, chartered for the occasion by the D. A. D. A., and will be afforded a glimpse of Detroit's water facilities. The boat will proceed down the river, past the world-famous Limekiln Crossing, Bois Blanc, Sugar Island, and other down-river resorts, to Lake Erie; then run up the river across Lake St. Clair, through the St. Clair Flats, the "Venice of America," and back to Detroit, reaching the city early in the evening.

Monday morning, July 12, at 9 o'clock, the Glidden tour will start from in front of the city hall with due éclat. The Maxwell band of the Maxwell-Briscoe Company will be on hand to provide music, and local motorists will be out in force to give the tourists a fitting send-off. Business will be intermingled with pleasure, although neither will be allowed to conflict with the other. The A. L. A. M., the A. M. C. M. A., and the A. A. A. officials will sandwich their annual meetings in between the festivities, which will make it a moderately busy season for all concerned. These gatherings will bring to Detroit practically every prominent automobile manufacturer in the country, and the local committee is bending every energy toward showing the visitors that Detroit is not only the center of a great and growing industry, but that it appreciates what their presence stands for.

Headquarters have been opened by the local committee at the Hotel Fuller, and from now on the pot will be boiling.

The 1909 Hower trophy for runabouts is now being exhibited in the window of an automobile dealer on Broadway, New York. As this trophy is a permanent possession, an entirely new one is put up every season. Last year the trophy was a plaque, handsomely mounted. This year it is a silver loving cup, having three handles and an inscription on each panel between the handles.

Numbers Assigned to Tour Entrants

BUFFALO, N. Y., June 21—Numbers have been allotted to the cars which have entered for the sixth annual tour of the American Automobile Association, and the cars have been sorted into groups according to the trophy for which they will compete. They are as follows:

FOR THE GLIDDEN TROPHY

No. 1	Premier	No. 12	Pierce-Arrow
No. 2	Premier	No. 14	Pierce-Arrow
No. 3	Chalmers-Detroit	No. 15	Glide
No. 4	Marmon	No. 16	Thomas
No. 5	Marmon	No. 17	Midland
No. 6	E-M-F	No. 18	Lexington
No. 7	E-M-F	No. 19	Stoddard-Dayton
No. 8	Maxwell	No. 20	Stoddard-Dayton
No. 9	Maxwell	No. 21	Stoddard-Dayton
No. 10	Maxwell	No. 22	White
No. 11	Jewel		

FOR THE HOWER TROPHY

No. 100	Moline	No. 107	Maxwell
No. 101	Moline	No. 108	Pierce-Arrow
No. 102	Moline	No. 109	Pierce-Arrow
No. 103	Brush	No. 110	McIntyre
No. 104	Brush	No. 111	Stoddard-Dayton
No. 105	Chalmers-Detroit	No. 112	Jewel
No. 106	Hupmobile	No. 114	Mason

FOR THE DETROIT TROPHY

No. 51	American Simplex	No. 53	Premier
No. 52	Chalmers-Detroit		

NON-CONTESTANTS

No. 75	Rapid Truck	No. 77	Diamond Rubber Company
No. 76	"The Automobile" and "Motor Age"		

OFFICIAL CARS

No. 98	Pilot, E-M-F	No. 99	Chairman, Premier

Indians Now Buying Autos—"Lo! the poor Indian" is a forgotten phrase on the Cheyenne River Indian reservation, for the redskins, just to show that they are not poor, as well as to enjoy the pleasures of touring, are investing in automobiles, according to reports from Pierre, South Dakota. The camera and the typewriter are also gaining general use among the redskins.

What the Clubs Are Doing These Days

BALTIMORE HAS ITS "BIGGEST" SUCCESS

BALTIMORE, June 21—Orphans' Day in this city, last Wednesday—a week later than scheduled time—proved a "biggest" success. It required 180 cars, donated by members of the Automobile Club of Maryland and other owners, to take the more than 900 little ones on their annual tour over the best streets of the city, and then to Electric Park, where they were the guests of honor on the shoot-the-chutes, carousel and other attractions until supper time. A substantial meal was then served. The committee of the club in charge, under Chairman E. A. Dolle, had made splendid arrangements, and the result was the most enjoyable of the several outings.

At noon the cars gathered in front of the clubhouse on Mount Royal avenue, and were divided into 16 divisions, each with a marshal, and dispatched to 15 different institutions, to get their happy guests. They returned and at two o'clock started in single file on a parade, amid the yells and whistles of the boys and girls. After covering several blocks of city streets they entered Druid Hill Park, and were reviewed at the Wallace Monument by Mayor Mahool, who was in a six-cylinder Oldsmobile driven by E. L. Leinbach, manager of the Olds branch. Chairman Dolle's committee was composed of: Frank W. Darling, C. Howard Milliken, Joseph M. Zamoiski and Emmanuel Daniel. Mr. Milliken was also chief marshal.

WHEELING ORPHANS HAVE RIDE AND PICNIC

WHEELING, W. VA., June 21—An automobile ride and a picnic featured the local observance of the national orphans' outing on Wednesday. Under the auspices of the Ohio Valley Automobile Club a great many automobiles were secured and gathered on that morning at 10 o'clock. The children were then brought from the various institutions and led by Mayor Schmidt in his car, were taken on a parade over the city streets. After this the cars were driven to Blayney's Grove for a picnic through the afternoon, and the return was made in the evening.

GRAND RAPIDS ORPHANS OPEN CLUB HOUSE

GRAND RAPIDS, MICH., June 21—The third annual Orphans' Day celebration of the local automobile club was combined with the formal opening of the new club house at Cascade Springs on Wednesday. It was the most successful from the point of numbers and enjoyment to the waifs of the city that has yet been held. Although a dearth of cars was expected 70 cars, 20 more than were needed, reported in the morning ready to carry the 200 homeless youngsters to Cascade Springs for their holiday, where they were cared for and feasted by their nurses and members of the club.

A NEW CLUB IN JERSEY—AT PLAINFIELD

PLAINFIELD, N. J., June 21—With nineteen charter members the Plainfield Automobile Club has been formed, and steps will be taken to include in the membership all automobilists in this city and neighborhood. The following officers were selected: President, Dr. F. C. Ard; vice-president, Harry W. Marshall; treasurer, F. O. Ball; secretary, J. H. Rankin.

ALTOONA AUTOISTS FORM AN ORGANIZATION

ALTOONA, PA., June 21—To promote better streets and county roads, owners of automobiles in this city have formed the Altoona Motor Club with the following officers: President, W. L. Hicks; secretary, E. J. Lomnitz; treasurer, W. W. Blake. An active campaign is being outlined and it is planned to join the A. A. A.

JOY FOR THOUSAND ST. LOUIS ORPHANS

ST. LOUIS, June 21—Fourth annual Orphans' Day was celebrated by the Automobile Club of St. Louis by giving 1,090 children a six-hours entertainment. Twelve institutions furnished the quota, of which a careful estimate was made, and in spite of an over-cast sky, and forebodings of a rain that did not occur, the youngsters had a merry time. Each one was provided with an American flag and the privilege of using the voice as loud and long as desired. Members of the club donated cars which were used from 9 a. m. to 3 p. m. and the occupants taken for a long ride. Alden H. Little was grand marshal and he provided each chauffeur with a printed form which may be of value to some other club next year. It read: "Do not exceed the speed limit. Mr. ———'s car. Go at once to ———, located at ———. Take as many children as you safely can and be sure a responsible attendant accompanies you. Give the children a ride of not more than —— hours, and report back to the same place for the next load. In case of trouble which cannot be fixed in 30 minutes, telephone A. H. Little at once, number ———. Please drive with greatest care as the children are not accustomed to automobiles." About fifty machines were used, and some took several loads of youngsters out during the course of the day.

Delegation of St. Louis Orphans Ready to Start

GALVESTON ENTERTAINS ORPHANS WITH A RIDE

GALVESTON, TEX., June 18—Orphans of the various charitable institutions were given their second annual outing by the Galveston Automobile Club on June 8, nearly 200 children being given a long ride by the 50 automobiles donated, and as much ice cream as they could eat furnished by a club member. The run started from the library on Tremont street, in the heart of the city, after the cars had collected the inmates from the homes, and a line formed in which electric autos took the lead. For an hour and a half the ride was around the city, with flags and horns supplied to the little travelers. Lunch and enough ice cream to satisfy the most ravenous youngster were given by one of the members of the club who is an ice cream manufacturer, after which the ride was resumed and the course laid to the seawall boulevard, up and down which the cars sped to the hearts' content of the occupants, and then returned to the institutions from which they had started. Pleasant features of the event to the club were found in the interest shown throughout the city, and by the fact that with 60 members nearly 50 cars were available, in addition, of course, to the enjoyment furnished.

BOSTON AUTOISTS MAY UNITE IN NEW CLUB

BOSTON, June 21—Another attempt to consolidate the Bay State Automobile Association and the Boston Motor Club is being made, and at a recent meeting of the directors of the two organizations terms for a merger were drafted. These have been submitted to the members for action, and it is expected that it will be favorable, thus uniting the bulk of the local autoists. The Boston Motor Club was organized about six months ago by some members of the Bay State Association and others, who secured a charter and elected officers but never had permanent quarters. In its membership are several prominent members of the trade, while others equally prominent remained in the Bay State. Several attempts to bring about a merger have been made but none of them has had any result.

The terms now proposed include the merging of the Bay State Association and the Motor Club in a third organization to be called the Bay State Motor Club; that members of both organizations who have passed their respective membership committees be admitted to the new club; that joint committees from the two organizations prepare a list of officers and a new set of by-laws, and that the assets of both organizations be placed in the treasury of the new club. The Bay State Association has called a special meeting to act on the matter on Wednesday, June 30.—It is thought that the members favor the move.

QUAKERTOWN, PA., AUTOISTS ORGANIZE CLUB

QUAKERTOWN, PA., June 21—So many of the residents of this place and of the surrounding country have purchased automobiles that the owners decided to join hands in order to push good roads and other work in this vicinity. Accordingly the Quakertown Motor Club has been formed with the following officers: President, Fred L. Harley, Quakertown; first vice-president, M. L. Cope, Perkasie; second vice-president, Dr. W. H. Brown, Richlandtown; third vice-president, C. F. Newcomer, Coopersburg; secretary, Howard R. Moyer, Quakertown; treasurer, Charles Stoneback, Coopersburg; solicitor, Harry E. Grim. A committee on by-laws is composed of: John Freed, Richlandtown; J. Howard Ozias and M. T. Free, Quakertown. The membership committee is: Dr. W. H. Brown, Richlandtown; W. O. Haney, Milford Square; Ralph Stauffer, Coopersburg; Mr. Kulp, Perkasie. One of the first acts of the club will be to request a repairing of the pike leading through Richland and Springfield townships to Coopersburg.

CHATTANOOGA AUTOMOBILE CLUB ORGANIZES

CHATTANOOGA, TENN., June 21—The Chattanooga Automobile Club has taken a new lease on life through reorganization, and a vigorous campaign for good roads and other matters of interest to autoists mapped out will be entered upon at once. The membership in the body will be limited to 150, and these must be private owners living within 50 miles of this city. At the recent meeting it was reported that 60 autoists have joined, and that there are 34 more applicants. The following officers have been elected: President, H. S. Probasco; vice-president, C. F. Milburn; secretary, C. E. Kirkpatrick; treasurer, L. W. Llewellyn; directors, B. F. Thomas, H. W. McCallie, Carl Painter, C. A. Raht, R. L. Williams.

KENTON, O., AUTOISTS WOULD BUILD PIKE

KENTON, O., June 21—The Kenton Automobile Club, which has a membership of more than 50 of the leading business men of this city, has made a unique offer to the county commissioners. The club asks permission to select a pike in Hardin county and improve it under the direction and at the expense of the club members, who wish to take a stretch of four miles of pike and entirely reconstruct it, making it a model highway. The club also asks the commissioners to place guide posts at every road crossing in the county, and has sent to Toledo and Columbus for copies of the traffic ordinance with a view of enacting a similar one here.

WARREN COUNTY, N. J., GETS A CLUB

WASHINGTON, N. J., June 21—Automobilists of this city and the surrounding country, more than 90 of them and all owners of cars, on last Wednesday evening met here and organized the Warren County Automobile Club. The members were addressed by F. H. Elliott, of New York, secretary of the American Automobile Association, with which the new body will be affiliated; and by W. C. Crosby, president of the New Jersey Automobile and Motor Club and also president of the Associated Automobile Clubs of New Jersey. The following officers were elected: President, D. M. Perry, Washington; vice-president, R. D. Huff, Hackettstown; secretary, W. H. Rhodes, Phillipsburg; treasurer, J. R. Bryant, Washington. Five directors were chosen, as follows: W. D. Gulick, Washington; J. R. Stires, Penwell; A. Blair Kelsey, Belvidere; Matthew Suttle, Phillipsburg; Dr. L. C. Osmun, Hackettstown. Dr. C. B. Smith, Washington, was elected as a director to the A. A. A., and Dr. W. C. Albertson, to a similar office in the Associated Clubs.

SAVANNAH CLUB TO MARK ROADS

SAVANNAH, GA., June 21—All good roads will lead to Savannah in a few months; at least this is what the Southern traveler will think after the Savannah Automobile Club has carried out plans which have been formulated by Secretary A. W. Solomon.

Mr. Solomon has ordered a large number of steel signs, in shape and color like the Savannah automobile pennant. The red-and-white sign telling the mileage to Savannah will soon be a familiar landmark on every road leading to that city, accessible to motorists. The indicators will be distributed through a territory within a radius of forty or fifty miles, with Savannah as the starting point. Autoists from the North, traversing these roads, will be given a taste of Savannah enterprise long before their arrival here.

BOULDER, COL., NOW HAS A CLUB

BOULDER, COL., June 21—Boulder Motor Club has been organized by the enthusiastic automobilists of this place, about 25 in number, and the following officers have been chosen: President, O. J. Watrous; secretary, C. L. Bennett. The committee on by-laws is composed of Dr. W. Scott, L. B. Overfelt and Louis Herman; and the committee on membership includes O. N. Gilbert, G. W. Blackburn and Ernest Grill. An invitation has been extended to the officers of the Denver Motor Club to meet with the local body to arrange a plan to secure better roads between this city and Denver. Similar work will be undertaken with other automobile organizations in the vicinity in order to have improved highways leading in all directions, especially into the mountains and to the North, toward Cheyenne and other Wyoming points.

HAMILTON, O., AUTOMOBILE CLUB IS FORMED

HAMILTON, O., June 21—With a charter membership of 50 owners of autos, the Hamilton Automobile Club was formed recently in this city. The officers of the old automobile club were adopted as the temporary organization of the new one, as follows: President, C. E. Hemp; secretary, Mark Sohngen; treasurer, Dr. F. M. Barden. It was decided to begin an active campaign for increased membership, and committees were appointed on constitution and by-laws, and on membership.

VICKSBURG, MISS., AUTOISTS ORGANIZE

VICKSBURG, MISS., June 21—Enthusiastic autoists of this city, in order to work together to obtain improved roads and other conditions, have formed the Vicksburg Automobile Club, and have chosen the following officers: President, Dr. R. A. Quin; vice-president, W. L. Nicholson; secretary, Lee Richardson; treasurer, J. J. Lum; directors, Dr. W. H. Penn, J. H. Hempen, P. S. Craig, A. A. Kuhn, G. L. Ryan, W. N. Dupree, J. W. Hayes, Jr., M. Kaufman, T. J. Hays, F. J. Fisher.

GOVERNOR VETOES NEW WISCONSIN LAW

MILWAUKEE, WIS., June 21—Governor Davidson has vetoed the Page bill, a statute to regulate automobiles, which had been passed by the Senate without a speed clause and amended by the House to have eighteen miles an hour in cities and twenty-five in the open country. The veto says in part: "My objection is based upon two propositions, the first of which is that it permits automobiles to be run at a rate of speed not to exceed eighteen miles per hour within the corporate limits of any city or village. . . . The laws of Wisconsin limit the speed of railroad trains running on a defined track, on schedule time, to twelve miles per hour in entering or passing through cities or villages. . . . A speed of eighteen miles per hour means that the vehicle may pass along populous streets twenty-six feet at every tick of the watch. This . . . is highly improper and dangerous." The other objection is that the section relating to penalty refers to sections of a statute previously passed instead of to the entire law, which would make convictions impossible, he says.

This action came as a surprise to those interested in the affair, for it was known that the Legislature was favorable by its actions and the clubs and State association were satisfied, but the Governor threw it out by his veto and sent it back to the Legislature a few minutes before the time set for final adjournment, obviating any chance of passage over the veto. The Owen-Chinnock bill, increasing the registration to $2 and requiring motorcyclists to pay, was signed, and all owners must re-register before October 1. When a car is sold the certificate and license tags have to be returned to the Secretary of State.

MARYLAND LAW RESTS IN DEADLOCK

BALTIMORE, June 21—At a recent conference of a committee from the Automobile Club of Maryland, with Osborne I. Yellott as spokesman, and the State automobile commission, it was impossible for the two sides to get together on the tax and license feature of the bill prepared by Colonel Sherlock Swann, a member of the commission, so that it will be necessary for the next Legislature to settle the differences. The commission held out in favor of the rates fixed some time ago, as follows: Under 20-horsepower, $6; over 20 and including 30-horsepower, $9; over 30 and including 40-horsepower, $18; over 40-horsepower, $24. The commission would have manufacturers and dealers' licenses arranged on a basis of annual business to $10,000, $25; between $10,000 and $25,000, $50; between $25,000 and $50,000, $100.

The autoists, according to Secretary Darling, of the Automoble Club, want the license arranged in this manner: Up to and including 20-horsepower, $6; over 20 and including 30-horsepower, $9; over 30 and including 40-horsepower, $12; over 40-horsepower, $15, provided that a wheel tax is imposed on all other vehicles within the State at the rate of 25 cents per wheel for one-horse pleasure vehicles; 50 cents a wheel for two-horse vehicles, and $1 per wheel for four or more-horse teams; with the further provision that such vehicles shall be required to have lights at night. This wheel-tax feature does not meet with the approval of the auto commission.

FOR ONE YEAR'S AUTO WASHING, $1.20

DETROIT, June 21—Hereafter owners of automobiles will have to pay $1.20 yearly for the water used in washing them. The reason is that the water board needs more money. The horse has been taxed for what it drank. Every truckman has had to pay for the privilege of bathing his vehicle. But to date the automobile has been immune. Now the buzz buggy has been promoted to the same rank as other vehicles. Whether it will appreciate the honor conferred is a question. At all events, it is anticipated that the man able to maintain a machine will manage somehow to scrape up the $1.20 levy imposed by the water commissioners.

Present indications are that ultimately some sort of a compromise may be effected, but the outlook just now is quite indefinite.

SOME OHIO REGISTRATION STATISTICS

COLUMBUS, O., June 21—The report of the State register of automobiles for the year ending June 10 is interesting as indicating the trend of the industry and the number of automobiles registered in the first fiscal year of the present law. During the twelvemonth there was 17,192 autos registered in Ohio, which produced a revenue of $82,406; manufacturers and dealers numbered 366, and the income from them was $3,660; there were 784 certified copies issued, totaling $1,568; altogether 2,741 chauffeurs took out licenses, valued at $5,482, and duplicate tags were issued to the number of 154. Owners' renewals numbered 226, producing $1,534, and the total revenue to the department was $94,835.

Amendments have slightly changed the law, for by the enactments of the last session of the general assembly, all licenses expire on December 31, instead of one year from the date of issuance. Renewal blanks are now being sent 10 days before the expiration of the license, and the renewals, as well as all new licenses, are for the remainder of the calendar year.

CONNECTICUT LAW LARGELY AMENDED

HARTFORD, CONN., June 21—If ever a proposed law was riddled to a record-breaking degree, it was the statute to regulate automobiles in this State, which received thirty-three amendments on Wednesday in the House, not all of which were carried, but a goodly number left their imprint upon the Senate measure. Matters of speed, licensing, and age of the operators were given most serious consideration. It was decided that no one under 18 years of age should be allowed to drive, changing the text from 16, and it was advised that an operator who has his license revoked could not secure another one for two years, instead of six months. The speed maximum stands at 25 miles per hour, with that in congested quarters amended to 10, and in passing trolley cars whch are receiving or discharging passengers 3 miles per hour. The clause requiring that an auto be timed over an eighth of a mile to show its speed remains, and a fine of from $100 to $500 or a sentence of from six months to one year in jail, or both, be applicable when a car injures someone and the driver tries to run away.

OHIO LAW GRATIFIES SECRETARY OF STATE

COLUMBUS, O., June 21—Secretary of State Carmi H. Thompson of Ohio has issued a statement in which he shows the benefits of the Ohio automobile law, which, he claims, has been good for the people and motorists generally. The statement follows: "I believe that the Ohio automobile law, which is comparatively new, having been in force only one year, is as well observed and as well enforced as in any other State, and that the records will show a far less percentage of arrests for non-compliance than in any other State. A great amount of the credit for the rigid enforcement of the statute is due the Columbus, Cleveland, and Cincinnati automobile clubs, all of which are affiliated with the American Automobile Association, and whose work has been in cooperation with the work of this department."

PRO-RATE FEES ACCORDING TO AUTOISTS

COLUMBUS, O., June 19—The bill of Representative Ritter increasing the registration fees for all automobiles in Ohio will not be the only auto bills before the next session of the General Assembly. Senator Cretone of Dayton will again introduce the bill under consideration last session which provides that the fees received from the registration of autos should be pro-rated among the counties of the state in proportion to the number of owners of automobiles in each county. He believes that counties which have none or few automobiles should not receive the same amount of money for their road funds as counties having thousands of cars. While many are of the same belief, they predict impossible difficulties in enforcing such a law.

Why Night Driving Lost Its Terrors for Autoists

NIGHT PHOTOGRAPH FROM THE EARLY DAY

THAT taking photographs of roadside scenes by night is not a recent practice is shown by the accompanying picture taken some years ago, and contributed by Gray & Davis, of Amesbury, Mass. This was taken by Louis Derr, of the Massachusetts Institute of Technology, using two Gray & Davis Bullet lamps, on a Locomobile steam car, and in describing the photograph, Mr. Derr then wrote: "The two bright spots and the smaller one between them, surrounded by circles, are the images of distant Welsbach street lights, the nearest being about 125 feet away, and the two brightest ones being on opposite sides of the street. The very faint spots near the middle of the picture are lights in a house.

"You will notice that the path of light from the car lamps extends up to the street lights, which themselves are not bright enough to light up the roadway sufficiently to show on the print. This gives a basis of comparison of brightness. The picture is not faked in any way."

REGAL 1910 CAR TO CROSS COUNTRY

BUFFALO, June 21—A pleasant little reunion took place in Buffalo on Saturday as an echo of the trip made by the Regal "Snowball Limited" early this spring. Those attending were Mr. and Mrs. Bert Lambert and Mr. and Mrs. Fred. W. Haines, of the Regal Motor Car Co., of Detroit; Mr. and Mrs. Pickard, Mr. and Mrs. Penfield and Mr. Sherman, of the Salisbury Wheel & Manufacturing Company, of Jamestown, N. Y.; Mr. and Mrs. Covert, of the Covert Motor Vehicle Company, of Lockport, N. Y.; R. Harry Croninger, of the Pennsylvania Auto Motor Works, and George D. Wilcox, of the Regal Sales Company, of Syracuse. Mr. Wilcox was the pilot of the "Snowball" on its mid-winter run.

A banquet was served at the Lafayette Hotel, after which the entire party were entertained at the theatre. Announcement was made at this gathering of the proposed trip of the Regal 1910 model, from New York to San Francisco, to leave on July 4. Mr. Wilcox will pilot the car and it will be driven by "Snowball Bill" Smith of the Regal factory. The gathering broke up with the best wishes from all for the success of the proposed trip. The car will be equipped with Empire tires and will carry four passengers.

MAXWELL-BRISCOE BUYS ANOTHER FACTORY

PAWTUCKET, R. I., June 21—The Maxwell-Briscoe Motor Car Company will shortly move from the plant which it has occupied in this place for four years to Auburn, R. I., where it has purchased the works of the Auburn Rubber Boot and Shoe Company. This factory was secured for $200,000 and is being remodeled so that the capacity will be twice as many automobiles as the present situation affords. The output at present is 2,000, employing about three hundred men, but at Auburn it is estimated by the factory officials, fully 4,000 four-cylinder cars will be built annually. The Maxwell output for 1910 will exceed 22,000 cars.

PREDICTS 1910 WILL BE MAGNETO YEAR

"Nineteen hundred and ten will be noted as a magneto year in the motor car calendar," says J. S. Bretz, president of the J. S. Bretz Company, importers of the Unterberg & Helme high tension magnetos. "Not but what magnetos have been largely used heretofore, but because the magneto will come into its own next year, and by this I mean the undisputed possession of the ignition field.

"Next year magnetos will be furnished as the integral part of a complete car, and not offered as an extra, or an option at an additional price, which sometimes means, in the hands of dealers, an increase of price way beyond the original cost of the magneto.

"Abroad nearly all the popular and well-known makes of motor cars are sold with the magneto as the sole source of ignition, up to at least 30-horsepower and hence it is expected that we will not much longer continue, excepting in big motors, which are hard to start, the idea of having a double set of ignition, which means two complete sets of plugs, wiring, etc., or the dual system of ignition, which really means a set and one-half.

"The sole advantage that both the double and dual systems have over the magneto system alone is the added ease of starting on the spark. On the U. & H. magneto, for large and small four and six-cylinder motors, and which we have been building for some years, we have added three important, well tried out improvements, which easily rank them first among high-tension magnetos which use batteries for starting purposes.

"The first of these improvements is the U. & H. interrupter, which is so designed that wear is really abolished, and as it permits of no adjustment, it is permanently set at the factory, hence after that there is no possibility of false adjustment. The second improvement is the locating of the high class battery timer in the magneto, at the end of the distributor shaft, the timer being advanced and retarded with the interrupter. The third, and not least of these improvements, is the construction of the distributor, which is designed with the idea of preventing the insulation being burned by the high tension spark when the engine is started on the battery switch. The distributor segments are set in a floating ring, which follows the spark advance and retard, but when retarded for starting the brush always touches the right segment."

WHAT IS GOING ON AMONG THE GARAGES

Pittsburg, Pa.—The Standard Automobile Company, through its president, W. N. Murray, has secured property in the East End, on which it will construct automobile salesrooms and garages. One lot is at Baum and Beatty streets, 100 feet on the former, 142 feet on the latter, and was purchased for $30,000. It is said that another lot has been bought by the same concern for about the same price on Baum street, with a frontage of 89 feet and a depth of 119 feet on its longest line, being fan-shaped. These are near several other garages.

Wellington, Kan.—Joe Fetters and Charles Lovingfoss will erect a garage at Eight and Washington streets, 50 by 140 feet in size, with two floors, the lower one to be used as a space for the automobiles, and the upper will be for an auditorium. The building will be constructed of stone.

Anniston, Ala.—Erection of a brick garage on Benson street, between Peoples and Tolly streets, has been commenced by J. S. Fowler. The building will be constructed of brick with a concrete floor and tin roof, 35 by 80 feet in size, and will cost about $1,000.

Kansas City, Mo.—Permits have been granted for the erection of a garage and warehouse at 1521 and 1523 Grand avenue. The building will have a frontage of 50 feet and a depth of 117 feet, two stories high. The estimated cost is $22,000.

Clarinda, Ia.—J. B. Eastman has just taken possession of his new automobile garage, which is one of the largest and best equipped in southwestern Iowa. It is 40 by 140 feet in size, with two stories and a basement.

Factory of the Nordyke & Marmon Company, at Indianapolis, Ind.

ENLARGING HOME OF MARMON

INDIANAPOLIS, IND., June 21—Extensive enlargements are now being made in the factory of Nordyke & Marmon Company, Indianapolis, the home of the Marmon car. The Marmon plant is already a very large factory, occupying eleven acres of ground, with a total floor space of 280,000 square feet, and employing 800 to 900 men. Several new buildings have been added in the last few years—two of these are not shown in the accompanying picture. Another building is now to be erected at the extreme rear of the plant, with floor space of 7,500 square feet. This latest addition will house the testing and repair departments, and the space formerly occupied by these departments will be used for enlarging the machine shops and final assembly floors.

In addition to the motor car product, Nordyke & Marmon Co. is also the world's largest manufacturers of flour and cereal mill machinery, the business having been established in 1851. Many parts of the big factory's equipment—such as forge shops, foundries, sheet metal and woodworking departments—are used for all the company's products.

Tires, lamps, gas tanks, Bosch magnetos, Hess-Bright ball bearings and similar equipment for Marmon cars are, of course, purchased outright by the company, but nearly everything else about the car is manufactured in this factory. Aluminum, bronze, brass and iron castings, sheet metal work, bodies, engines, transmissions, axles, steering gears—in short, about everything is manufactured from the raw material. One department is devoted exclusively to the preparation of tools, jigs, patterns, etc., so that the interchangeable parts for almost any piece of machinery ever produced by the company can be duplicated accurately and with promptness.

All the buildings are well ventilated and lighted and contain an elaborate system of overhead and surface tracks. Shipping facilities are unexcelled.

The enlargements now being made and additional equipment being installed will permit a greatly increased output of Marmon "thirty-twos" for 1910.

The 1910 output will be confined exclusively to the "thirty-two" in five-passenger touring car, four-passenger short-coupled car and roadster. Since no changes of consequence over the 1909 will be made, the company will be able to complete the 1910 production early. Deliveries will begin in August.

GENERAL ITEMS OF INTEREST

Few Changes in New Banker Wind Shield—To keep the pace with the automobile manufacturers, the Banker Wind Shield Company has arranged to place its 1910 models upon the market very shortly, and will make early deliveries. George A. Banker has taken up the management, in the place occupied by Arthur L. Banker until recently, and states that the new types will present few changes in design or appearance, the principal one being in a new and improved telescoping rod which is constructed to permit of raising or lowering the glass without the driver's leaving the seat. This feature is obtained by means of an expanding and contracting cone, placed inside the telescoping tube and fitted at the end with a small knurled wheel that tightens or releases the tension as desired. This improvement does away with the nut used heretofore and obviates the necessity of getting out of the car and using the wrench.

Firestone's Record in Trans-Continental—With three cars in the endurance contest from New York to Seattle equipped with the Firestone tires, the Firestone Tire & Rubber Company is keeping close tabs upon their behavior. When the cars started it was noticed that neither of the Fords carried spare shoes, and when this was remarked upon Mr. Ford said: "The car is light enough, and the tires good enough to go through without the use of extra tires." At Denver, H. B. Harper, advertising manager of the Ford company, telegraphed that Ford No. 1 had two and Ford No. 2 had three of the Firestone tires filled with original air. Salzman, in the Acme, reported from Denver with three of the original Firestones in perfect condition, although six pairs of chains had been worn out. From Rawlings, Wyo., he telegraphed that his mileage was 2,674 and the tires still looked like new.

Niagara Power for Franklin Factory—The falls of Niagara, over 150 miles away, are furnishing electric power with which to run the plant in Syracuse, N. Y., in which the Franklin automobiles are made. Niagara power has run the trolley cars and lighted the streets of Syracuse for a year or two, and the H. H. Franklin Mfg. Co. has for some time had available a partial use of cataract power for emergency service. This it has now doubled, making provision sufficiently for its entire factory. This does not mean that the factory will be dependent upon or always use the Niagara electric current. Its own power plant will be used through the winter and most of the year, but in the summer, when power alone, without heating is wanted, the electricity generated at the falls will turn the factory's machinery.

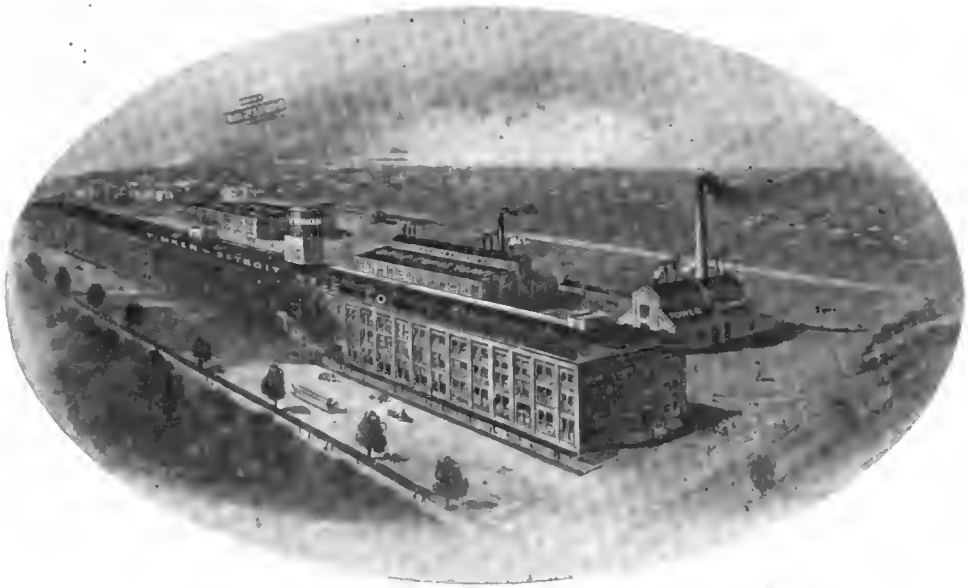
Morgan Truck Waters Dead Horse Hill—In the recent hill climbing contest at Worcester on the Dead Horse Hill it was planned to sprinkle the course between every two events with a 40-horsepower Morgan Trade Motocar, carrying a temporary tank and sprinkling device. The rain, however, had laid the dust so well that it was not needed. Just to show that it was able to do so, if necessary, the big machine covered the entire distance in less than 15 minutes, including stops, the day before the contest. The contest committee of the Worcester Automobile Club decided that the use of one automobile would be better and quicker than eight horses, with one or more tank wagons. In making the climb the Morgan truck had no extra weight on board, but it had no difficulty in keeping traction.

Remarkable Empire Tire Record—The Empire Tire Company, of Trenton, N. J., has found considerable satisfaction in the record of its tires upon cars in recent endurance contests. The latest perfect performance was in the Catskill-Berkshire tour of 350 miles, in which a Thomas taxicab and a Columbia touring car each finished with perfect scores, mechanical and tire. In six different contests, therefore, Empire tires have been used without a single puncture, as follows: Motor Club of Harrisburg, 690 miles, two cars; Norristown Automobile Club, 374 miles, two cars; New Jersey Automobile and Motor Club, 193 miles, one car; Delaware Valley endurance run, 158 miles, nine cars; run-off of Delaware Valley tie, three cars; Catskill-Berkshire tour, two cars.

Locomobile Wins Hill Climb Abroad—It is always gratifying to Americans to learn of instances where American cars beat foreign made machines in competition on the latter's own soil. At the Call d'Aspin Mountain climb in the Pyrenees, France, on June 3, a distance of 93 kilometers, nearly 60 miles, Z. K. Graham of Los Angeles, Cal., who is touring Europe in his Locomobile "40," won a signal victory, beating his nearest competitor by more than 20 minutes. Among the contenders were a Mercedes, two Panhards, a Wolseley, Hotchkiss, Renault and Gladiator. Mr. Graham's car was the only American contender.

"The Q M S Company" a Simplified Name—In order to simplify details in connection with correspondence, telephoning, etc., the Quincy, Manchester, Sargent Company, Plainfield, N. J., has changed its name, and hereafter will operate under the corporate name of the "The Q M S Co.' This change has been under consideration for some time, many friends and customers practically demanding it, one great objection to the old name being the inconvenience and time consumed in pronouncing the full name over the telephone, according to factory officials.

KisselKars in Demand—This season's sales of KisselKars, according to the Kissel Motor Car Company, have been so far ahead of the best expectations that additional manufacturing space has become necessary, and some increases have already been made. The selling territory has been greatly expanded, new agencies arranged, and the factory has



How the Timken-Detroit Plant will Look When Doubled in Size

been rushed to supply the demand. One telegram is given as coming from a California agent, as follows: "Ship by carloads as fast as possible until told to stop." The company engineers are busy planning the 1910 models and predict some interesting announcements.

Atwater-Kent Again Enlarges—The Atwater-Kent Manufacturing Works, Philadelphia, maker of the well-known Atwater-Kent Spark Generator and Unisparker, is again doubling its capacity, this being the second expansion which this concern has undergone in eight months. The change was made necessary by the fact that the Atwater-Kent Manufacturing Works will supply twelve new concerns this year with ignition goods as standard equipment, and it became imperative to secure quarters for more workmen and more machinery.

Standard Sales Company Introduces New Plug—To introduce its new spark plug, which is suitable for either magneto or battery, the Standard Sales Company, Broadway and Fifty-seventh street, New York, has arranged to send a sample plug to any address for 25 cents. The concern takes this method in order to get the plugs into the hands of the owners, and it is necessary for the sender to give the name of his supply house and also to state the thread desired.

Regal Company Erects Addition—The Regal Motor Car Company, of Detroit, is constructing a large increase to its plant at Beaubien and Trombly streets, so that its capacity for 1910 will be 3,000 cars. The concern has recently been incorporated.

Georgia Buggy Company to Build Autos—The Dublin Buggy Company, Dublin, Ga., has increased its stock by $50,000, and will add the manufacture of automobiles. A one-story brick building, 80 by 200 feet in size, will be erected.

Will Manufacture Automobile Wheels—The West Chester Wheel Works, of Chester, Pa., is to add another department to its plant and will manufacture automobile wheels in it, beginning in about a month.

TIMKEN-DETROIT AXLE CO.

CANTON, O., June 21—For the fifth time in seven years the business of the Timken Roller Bearing Axle Company has doubled, and this time the greatest move in the history of the concern has been made. By dividing the manufacturing of roller bearings from that of making automobile and other axles, an enlarged output in both branches has been secured. The Timken-Detroit Axle Company has been formed and capitalized at $1,000,000 to manufacture the axles in Detroit, while the plant in this city will hereafter be known as the Timken Roller Bearing Company, and will produce roller bearings exclusively. Machinery is now being installed in the local factory which will just double its present capacity.

In Detroit, large and modern buildings on Clark avenue and the Pere Marquette Railroad were secured some months ago and prepared for occupancy. The drop-forge plant was increased and other improvements made so that the output of axles will be one of the largest in the country. Ample facilities and capital are at hand, and a great deal of business has been booked for 1910. The officers of the Detroit company are: President, W. R. Timken; first vice-president, H. H. Timken; second vice-president and factory manager, A. R. Demory; secretary and treasurer, E. W. Lewis; chief engineer, H. W. Alden; assistant secretary, F. C. Gilbert; purchasing agent, W. H. H. Hutton, Jr. The active management will be in the hands of Messrs. Demory, Lewis and Alden. Operations have already commenced, and in July the full product of the concern will be coming through.

SHANKS A REAL ESTATER

Considerable surprise has been expressed in automobile circles by the announcement of Charles B. Shanks, one of the most successful men in the advertising and sales ends of the industry, of his intention of entering the real estate business in Spokane, Wash., in connection with Fred A. Jacobs, the largest operator in that section of the country, the firm to be called the Jacobs-Shanks Company. Mr. Shanks is at present sales and advertising manager of the F. B. Stearns Company, Cleveland, and he will leave that concern about August 1. He entered the automobile business ten years ago as publicity and advertising manager of the Winton Motor Carriage Company, later being advanced to the sales managership, and one year ago resigned to organize a company to retail automobiles in Cleveland. When that was well under way he transferred the management and took up his present position with the Stearns Company.

PERSONAL TRADE MENTION

Charles Stein, of the Stein Double Cushion Tire Company, Akron, O., is now taking full charge of the pneumatic tire department of his company, and will hereafter spend the greater portion of his time in placing agencies throughout the country. Mr. Stein is the inventor of the Stein tires as well as a number of improvements in the construction of solid tires, and is known as an expert in the rubber business.

E. LeRoy Pelletier, one of the most prolific producers of live copy in the automobile world, and whose energies of late have been directed toward exploiting the E-M-F car has, under the new arrangement whereby the Studebaker Company takes over the E-M-F product, been made assistant to the general manager of the Studebaker Company and also director of sales and advertising manager.

B. E. Brown, of Pittsburgh, has been appointed district manager of the Helios Manufacturing Company branch in that city. The Helios company, of Philadelphia, is the manufacturer of storage batteries for ignition and electrical vehicle purposes, and in a Woods car made a run of 152 miles on one charge to Atlantic City and back.

J. J. Evans has resigned the general sales agency of the automobile department of Abendroth & Root Manufacturing Company, of Newburgh, N. Y., the makers of Frontenac cars.

TAXICAB AND TRANSIT

Another Auto Line to Gettysburg, Pa.—With which to establish an automobile line between Thurmont, Md., and Gettysburg, Pa., two large autos have been received at the former town, each of 30 horsepower and with seats for 12 passengers. One car will be run between Thurmont, where it will connect with the Washington, Frederick and Gettysburg railroad, and Emmitsburg. The other car will run between Emmitsburg and Gettysburg, the two machines meeting in the former town.

Baton Rouge, La.—It is likely that a line of automobiles will be put on by the Baton Rouge & Hammond Railroad, connecting Covington, Hammond and Baton Rouge. At present the only train is a mixed freight and passenger, which is slow and unsatisfactory, but the company claims that the cost would prohibit running another train for passengers only and is considering the establishment of a motor-driven train, or automobiles mounted upon railroad wheels.

Pittsburgh, Pa.—The Wells Fargo Express Company is about to try automobile truck service in this city, and if its success is proved, will extend it to every city in which the concern has an office. The American Express Company, which has been using trucks in some places, has not tried them here because of the heavy grades. It admits, however, that the horse must soon go because of the increasing business.

Boston—The Malden Auto Express Company has bought the business of the Benjamin & Vaughn Express, which has been running an express business between Boston and Malden. Five trips a day will be made by the machines and wagons of the new company, and a local car will be used in Malden. J. Frank Vaughn, of the older concern, is senior member of the new one.

Great Western Taxicabs in Chicago—The Model Automobile Company has entered into an agreement with its Chicago dealers to place Great Western cars in taxicab service in that city.

IN AND ABOUT THE AGENCIES

Firestone, Seattle, Wash.—The Firestone Tire & Rubber Company will open a direct Seattle factory branch on July 1, to care for a greatly increasing trade in the Northwest. The establishment will be at 918 East Pike street, and is the tenth branch to be opened. The Firestone company also has 25 general distrubuting agencies for Firestone tires and demountable rims.

Packard, Philadelphia—Plans have been prepared for the Keystone Motor Car Company for the addition of three stories to its four-story building on North Broad street. When this is completed the Quaker City agent for the Packard will have one of the largest local automobile establishments in the world.

Peerless and Pope-Hartford, Detroit—The J. H. Brady Auto Company, agent for the Peerless and Pope-Hartford automobiles, has removed to its new building at Jefferson avenue and Beaubien street. This company has secured the agency for the Hudson cars.

Regal, Detroit—The Regal Motor Sales Company has moved to its new garage at Alexandrine and Woodward avenues. It has recently been incorporated.

NEW AGENCIES ESTABLISHED

Chalmers-Detroit: Fort Worth, Tex.—Runnels Auto Company, Second and Throckmorton streets.

Great Western: St. Louis, Mo.—The Albert Sterne Motor Car Company, 4130 Olive street.

Interstate: St. Louis—Lindsay Motor Car Company, 419 North Euclid avenue.

Rider-Lewis: Bellefontaine, O.—M. E. LeSourd, 300 Columbus avenue, east.

Mitchell: Waycross, Ga.—Gilbert M. Younglove, LaGrande building.

Rider-Lewis: Savannah, Ga.—Hazzard & Brocket, 320 Broughton street.

Pope-Hartford: Chicago.—Joseph Deibler, for the State of Illinois.

Rider-Lewis: Hackettstown, N. J.—J. W. Dalrymple.

Middleby: Newark, N. J.—M. and M. Auto Company.

Moon: Tampa, Fla.—Wilson, Trawick & Denham.

Lozier: Pittsburgh, Pa.—Banker Brothers.

RECENT INCORPORATIONS

Tribe Automatic Headlight Company, Worcester, Mass.—Capital $200,000. To manufacture and sell headlights for automobiles, locomotives and street cars. President, Charles F. Pharaoh; treasurer, George T. Tribe; clerk, Edmund R. Cummins.

K. E. Auto & Electric Company, Birmingham, Ala.—Capital $10,000. To deal in automobiles and electrical supplies, and to do repair work. Officers: President, Kyle Elliott; vice-president, T. G. Erwin; secretary and general manager, L. C. Kyle.

Consumers' Auto Supply Company, Pittsburgh, Pa.—Capital $25,000. To manufacture, sell, and deal in all kinds of supplies for automobiles. Incorporators: E. C. Neagley, M. L. McKain, B. L. Sionecker. Delaware corporation.

Philip C. Traver Manufacturing Company, Far Rockaway, N. Y.—Capital $50,000. To manufacture accessories for automobiles, bicycles and carriages. Incorporators: Philip C. Traver, Lewis Pearsall, George Breng.

Memphis Taxicab Company, Memphis, Tenn.—Capital $100,000. To operate taxicabs and other automobiles. Incorporators: S. M. Neely, N. C. Perkins, E. B. Le Master, G. G. Albon, S. H. Trezevant.

Plainfield Auto Bus Company, Plainfield, N. J.—Capital $50,000. To operate autobuses and other automobiles. Incorporators: A. R. Force, A. Tepper, M. Mendel, F. C. G. Martin.

Custead Motor Vehicle Company, New York.—Capital $100,000. To manufacture automobiles, etc. Incorporators: William D. Custead, Charles F. Di Dion, Arthur M. Von.

Carthage Automobile Company, Carthage, Miss.—Capital $10,000. To operate an automobile line between Canton and Carthage. Incorporators: R. L. Jordan, J. A. Walker.

New York & Queens Auto Truck Company, New York City—Capital $10,000. To operate buses and trucks. Incorporators: E. J. Forham, H. H. Browne, J. J. Harper.

E. R. Thomas Motor-Branch, Buffalo, N. Y.—Capital $100,000. To deal in automobiles. Incorporators: Edwin L. Thomas, J. M. Edsall, M. E. Dirnberger, Jr.

Regal Motor Car Company, Detroit—Capital $100,000. To manufacture automobiles. Incorporators: Charles E. Lambert, John E. Lambert.

Maxwell-Briscoe Motor Company, Detroit—Capital $1,500,000.

NEW TRADE PUBLICATIONS

Electric Welding Products Company, Cleveland—Two booklets have been issued by the Electric Welding Products Company illustrating their finished steel bolts and screws, and their valve stems and other electrically welded materials. These books are handsomely gotten up, with fine typography and clear cuts, and thus altogether attractive. They treat of the methods of welding the products, as well as the reasons for using these in preference to cutting down bolts, etc., from solid stock. Valves may be made by this process with nickel steel heads and carbon steel stems, and brake or gear shifting levers of steel with brass or bronze handles. The books are intended for the automobile trade, dealing with products used in the construction of the cars.

Continental Caoutchouc Company, New York City—Buff-colored folders, containing five photographs showing the different operations necessary in removing and replacing a deflated tire on a Continental demountable rim, have been issued by the Continental Caoutchouc Company. These are being sent to every automobile club in the country, and are artistically and neatly gotten up.

PARTRIDGE BEEFSTEAK DINNER

NEW YORK, June 21—As a farewell dinner before starting upon a vacation tour to Europe, E. S. Partridge, of the firm of Wyckoff, Church & Partridge, last Thursday evening gave a genuine "beefsteak" repast to more than a score of prominent New Yorkers. The gathering was at Lüchow's in true Bohemian fashion, and with white aprons and hats on the host and guests, the steaks were served upon big kegs instead of the conventional tables. Those present were: E. S. Partridge, Judge Loren Zeller, Percy Yalden, J. E. Demar, B. F. Nathan, J. P. Goodwin, August Luchow, G. T. Stockham, E. Gibbs Murphy, George Rector, George Johnson, A. Weiss, James Chism, I. H. Manning, C. W. Wurster, H. M. Swetland, Oscar Warner, Arthur Lesser, C. G. Drum, Howard Drakely, G. H. Gantert, Alex. Dow, Morris Rothchild, A. W. Church, Arthur Hildebrand, Guy Vaughn, S. C. Carrie, H. E. Wagner and A. J. Pickard. As a mark of their esteem, the W. C. P. force presented Mr. Partridge with a fully equipped and very handsome traveling case.

Mr. Partridge sailed on Saturday and will be away about six weeks. He took with him a Stearns touring car equipped with Continental tires and a new model of the Warner instrument. With the car he will tour in England and upon the Continent and may establish agencies in London, Paris and Berlin, in answer to many queries received from Europe during the past year as to the Stearns product. One of the interesting news items which appeared at the dinner was that the third 1909 series of Stearns cars will contain some real surprises, and that the first will be ready for delivery by August 1, at which time Mr. Partridge will be back to supervise the distribution of the fall and winter allotment. During the past year the company has sold in this city and the East more than twice as many cars as it did the previous year and would like to have had more cars to sell. During the coming year, however, the firm has determined not to be caught napping and has already placed blanket orders to ship as many Stearns cars as the big Cleveland factory can produce for the eastern territory. The new yellow taxicabs have been very satisfactory.

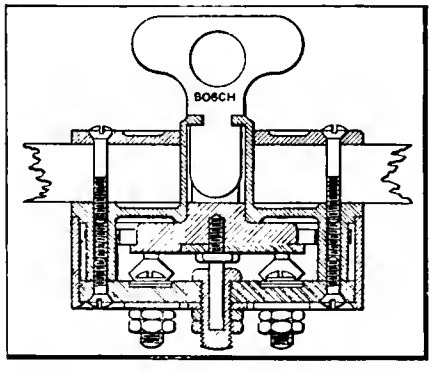
When the Guests Surrounded the Festal Board at the Recent Partridge Beefsteak Dinner

Information for Auto Users

Grade Percentage Indicator—There is but one standard for the measurement of grades, the rise in 100 feet, which, of course, is also the per cent. Every grade meter should read in terms of this, so that different slopes may be compared intelligently, although it is a fact that many of them do not. A new measuring instrument, known as a gradometer, has this as the principal feature. Not only does this new instrument measure and indicate the percentage of the grade, but it indicates to fractions of 1 per cent. just as delicately as the higher amounts. The exterior form of the instrument is very pleasing, and, to prevent cheap copies being made, the makers have registered the shape. It is of highly polished brass, measuring 7 inches in height, with a 2½-inch dial. The latter is silvered to make the letters read more plainly. The method of attaching it to the dashboard, the only place for such a handy and handsome instrument, is by means of screws, three being necessary. It is made abroad and sold in this country by Samuel Buckley & Company, 225 Fifth avenue, New York City.

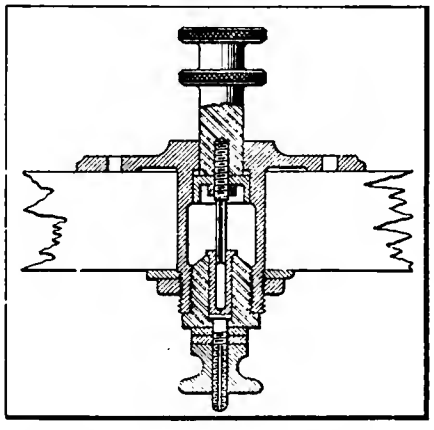
KIPLING GRADOMETER

A New Ignition Lock—The name of Bosch has always been associated with articles of merit, and the latest products of the Bosch factory are no exception to this rule. In the key switch designed for use with dual ignition, is found something to fill a long-felt want. This is provided with a large, flat key, which may only be withdrawn when it is perpendicular. In this position the magneto windings are connected to the ground, while the battery circuit is opened. In this way it is impossible to operate the engine. With the key in position, a turn to the left puts the magneto back into business, or a turn to the right allows the use of the battery system. The key is spring-held in any one of the positions, which are regulated as well by stop pins abutting against the posts, to which holding screws are fitted.



BOSCH IGNITION LOCKING SWITCH

A second new product is the dashboard switch. This consists of a large diameter plate, from the under side of which projects a hub. The latter houses the mechanism of the switch and protects it from dirt, dust and injury. Arranged to just project through a one-inch dashboard, this mechanism is very simple. A hard rubber handle is attached to a ferrule, which makes the contact with the body of the switch when the handle is pulled out. At the same time, the cable attached to the inside end of the ferrule is grounded. Both devices are sold in this country by the Bosch Magneto Company, 223-225 West Forty-sixth street, New York City.

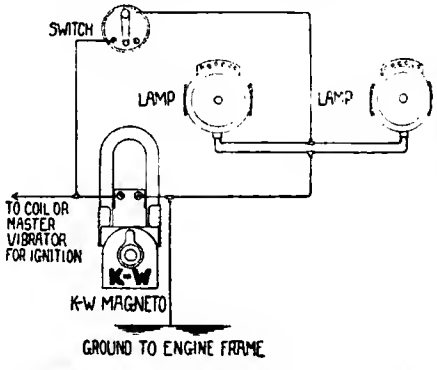


BOSCH DASH SWITCH IN SECTION

Koen's Folding Table and Chairs—For the use of automobilists, campers, boatmen and others, where a portable chair or table is desired, the Buffalo General Manufacturing Company, Buffalo, N. Y., is marketing the Koen patent folding chairs and table. The chairs are of the revolving, as well as folding type, suitable for tonneau seats or for use in a motor boat. Four kinds are made, with the price depending upon the upholstery or general finish; and one is so designed as to fold up against the side of the car or boat; another to have the back fold upon the seat, mounted upon a pedestal. The table is applicable for places where light lunch is served, for office work and more especially for traveling or camping. It lends itself to ready adjustment and packing.

The Autoist's Rabbit Foot—Strange as it may seem in a non-superstitious people, there is at present an unprecedented demand for good luck emblems. To meet this demand all of the leading dealers are laying in large stocks of the various lucky charms now made. The Motor Car Equipment Company, 1727 Broadway, New York City, is going into this line very extensively, and in addition to Gobbo, "The God of Good Luck," is making up a number of emblems of different fraternal orders in various s and suitable for radiator caps. include the emblems of the Masonic ternity, Elks, Woodmen, Knights of lumbus, and many others. They are out in all finishes, 24-karat gold, sil and antique brass.

K-W Magnetos to Supply Electric Lights—Automobilists are always glad to hear of a simple method of lighting their lamps by electricity, especially from a source which does not add complications. The K-W Ignition Company, Cleveland, O., manufacturers of the K-W magneto, announces that after extended experiments the K-W magneto has proven itself suitable for ignition and lighting purposes at the same time. Connections are made, as shown in the illustration, to electric bulbs in the searchlights, and the switch is located wherever convenient, but the lighting system is entirely distinct from that furnishing ignition. The company states that the tests failed to show any depreciation of the ignition current when the lights were turned on, and that the lights are also of ample power for use in the large searchlamps. In discussing the new system J. A. Williams, president of the company, says: "We have known that the K-W magneto would run lights successfully, in addition to ignition, but we have been conservative, and have made lengthy tests which have satisfied us that a combination is practical and we guarantee it. There is ample current to furnish both lights and ignition at the same time, and when the electric light is placed in a parabolic reflector the rays are thrown straight ahead and concentrated, so as to light objects several hundred feet away. When the motor is slowed down there is a slight variation in the light due to the change of speed, but it is very slight, and not enough to figure. The lights, on the other hand, do not have any effect upon the ignition, provided that the proper lamps are used. Another feature of the magneto is that the nature of the alternating current with the principle of the armature reaction keeps the voltage within very close limits. Six-volt tungsten lamps of a capacity that will draw about five amperes as a total load are the best. If one lamp is used it should draw not more than five amperes; if two lamps are used, we suggest that they should be two and one-half ampere lamps; while for motorboats we would advise the use of one two-ampere lamp and three one-ampere lamps. The lamps should in any case be tungsten types, which give three or more times as much candle power as the ordinary carbon lights."



K-W MAGNETO ELECTRIC LIGHTING SYSTEM

STROMBERG CARBURETORS

THREE REASONS WHY STROMBERG CARBURETORS ARE THE BEST

Power

A perfect mixture at all speeds is absolutely necessary in order that a motor may develop its maximum horse-power. On account of the design and control of the auxiliary air valve in a STROMBERG CARBURETOR, a perfect mixture is certain on any speed. For this reason the motor will give excellent service, equally well on low, intermediate or high speeds.

Speed

The design of the STROMBERG CARBURETOR compels it to automatically clear itself, and never allows it to become choked or filled when properly adjusted. This one thing alone means greater speed than any other; not only ability to retain high speed, but to speed up quickly after being slowed down.

Simplicity

There is only one absolute adjustment on a STROMBERG CARBURETOR, and that is to set the auxiliary air valve first for low speed with the knurled adjusting nut underneath, then for high speed with the nut above the valve. After a STROMBERG CARBURETOR is once adjusted it needs no further attention. Adjustments are self-locked.

The justly CELEBRATED 8-Day, High-Grade

"CHELSEA" AUTO CLOCK (Trade Mark)

Clocks built with a view to stand the jars and jolts and rough riding of Automobiles. Reputation the highest. Used by parties demanding the BEST.

ALL SIZES STATED ARE THE APPROXIMATE DIAMETERS OF THE DIALS.

All are 8-day High-Grade. All are in DUPLEX (patent applied for) polished cast brass cases, the most thoroughly water-proof case on the market. The "SPECIAL" clocks show dial on an angle; the inner cased clock when removed from outer (locked) case is excellent for use on mantels, bureaus, etc., when touring; its outer case is screwed to dashboard by hidden screws. The "SPECIAL" clocks are in large demand from dealers for owners of finest cars.

The MOTOR CLOCK has the same clock movement which for years we have supplied for the hard use on Locomotives, Steam Fire Engines, etc.; its dial is of same appearance as the AUTO Clock dial, but the Auto Clock movement has a somewhat finer train.

The 3 1-2 MOTOR "OFFSET" is likely to prove a quick, ready seller. Very attractive.

——PRICE LIST——

Size	"Round"	"Offset"	"Special"	"Limousine"

AUTOMOBILES of all kinds bought and sold. Largest New England dealers. Braley & Myers, 66 Berkley St., Boston, Mass.

AUTO BARGAINS!

The Times Square Automobile Company announces the opening of their St. Louis branch house, 18th and Pine Sts., St. Louis, Mo., where, as has been our policy for nearly ten years in New York, and now in our third year in Chicago, it is our purpose to buy high-grade used cars from owners wanting quick cash, and in time sell these cars to the general public on but a small margin of profit, relying for our remuneration on quick sales and the volume of business, rather than large individual profits. With our vast experience we can judge good cars, and give our customers the benefit of our best efforts. We are the largest dealers in new and used cars in the world; no matter what car you want, we have it. We have at present on the floors of our various buildings an exceptionally large and good line of popular makes and reliable automobiles. If the saving of money is an object, you will do well to communicate with us either in person or by mail. The Times Square Auto Bulletin will prove valuable and interesting to you whether you are an owner or a prospective buyer. It contains 48 pages of live auto matter and describes 300 cars, giving particulars and prices. Single copies free. Deal with a responsible concern. The Times Square Automobile Co., 215 and 217 W. 48th St., New York; 1332 and 1334 Michigan Ave., Chicago, Ill.; corner 18th and Pine Sts., St. Louis, Mo.

AUBURN 1908 Touring Car, full equipment, top; run 1,760 miles; guaranteed perfect; want smaller car. A. F. Klett, Rexmont, Pa.

AUTOMOBILE BARGAIN.—$1,000 will buy good as new $5,000 touring car. "S. S.," care The Automobile.

BUGGY AUTO.—"Kiblingen," practically new; cost $400, sell $125; not good on our sandy roads; first check gets it. S. Parker, Pine Town, N. C.

CADILLAC one-cylinder touring cars, with gas lamps and tops; one 1906, in good condition; one 1907, overhauled, every worn part replaced, a guaranteed job, running boards, newly painted. Harry M. Eastman, Melrose, Mass.

CADILLAC—Light touring car, new, 24-H.P., two-cylinder engine; all the working parts are new; five tires, six tubes, in good shape; lamp, generator, etc.; car as good as new; $550. Address Lock Box 136, East Palestine, Ohio.

COLUMBIA touring car, 2-cylinder, 18-H.P.; cape top, wind shield; good running order. 2923 N. 9th St., Philadelphia, Pa.

COLUMBIA Electric Victoria, 44-cell Exide battery; cost $4,000, 1907; will sell for $1,000. Mrs. Edw. Ellis, 215 Union St., Schenectady, N. Y.

CORBIN touring cars and runabouts, $800 and up. Thoroughly overhauled by us and guaranteed. Corbin Motor Vehicle Cop'n of N. Y., 1888 Broadway, near 62d St., New York City.

EXCEPTIONAL BARGAIN! 1909 six-cylinder, Model H Franklin, seven-passenger touring car; absolutely new; with special blue-striped show body; tires not soiled; regular equipment, including seat covers, top, glass front, etc. Immediate response necessary; will consider exchange for Lozier or gilt-edge securities. Westcott Garage Company, Utica, N. Y.

FASTEST car in the world for sale, 120-H.P. Address A. Hoh, 340 Willoughby Ave., Brooklyn, N. Y.

FIVE and seven-passenger high-grade touring cars. Factory overhauled and refinished. A better proposition by far than a cheap new one. Also many other desirable cars at prices that will surely interest you. E. R. Thomas Motor Co., Dept. S. H., 1200 Niagara St., Buffalo, N. Y.

LOOK AUTO OWNERS, BEGINNERS, CHAUFEURS!!
MASTER THE AUTOMOBILE
Study during spare time at home.
Dyke's Course of Auto Instruction only $10.00 now.

This Course is not one of theories, but rather a practical application of theories. I know it is the most practical and Comprehensive Correspondence Course in existence on the subject of the Automobile Construction. But this did not content me. I wanted a system of instruction that would surpass the training given by resident as well as other Correspondence Schools. The addition of the Working Models gives the Course unquestionable supremacy.

Different From a Book.

"Your Course of instruction on the Automobile purchased by me recently was beyond my expectations. I have read several Automobile Books, but this Course I find is different from matter obtained from reading a book. I find the instruction books prepared are so simple and plain that anyone can learn all about the Automobile with very little effort.

The Working Models are helpful in picturing the details and further simplify the subject.

The entire Course is interesting and instructive and the amount I paid you has been well invested. Yours truly, C. B. CARTON.

NOW ON SALE

AUTOMOBILE CATECHISM

For the Use of Owners and Drivers of Cars Fitted with Internal Combustion Motors

By

FORREST R. JONES, M.E.

President of the Manhattan Automobile School

THIS is the most practical, up-to-date work on the subject in the English language. It is published in pocket-book form, with high grade leather cover, and printed on especially tough paper, as it is intended to be the inseparable companion of the autoist when on tour. Not a line is wasted on obsolete constructions or descriptions of unfamiliar apparatus. It treats of the automobile in modern form and of all the troubles that may arise in the course of ordinary use and that may be remedied by the driver himself. It is written in plain language and is the most helpful, authoritative and comprehensive manual that has yet appeared. The subject-matter is in the form of question and answer, and an exhaustive cross index makes immediate reference possible in any particular case.

Size, 4 1-2 by 7 inches. Pages, 134. With Drawings.

Price in genuine Morocco Cover, gilt edges,

$2.00

Including postage.

Only the WARNER Auto-Meter is Trusted on the Thomas Pathfinder's Terrific New York to Seattle Trip

NOTE THE CONDITION OF THE ROADS

Because absolute accuracy was demanded at all speeds and under all conditions, The Warner Auto-Meter was selected for use on the New York to Seattle Thomas Pathfinder on its **Grueling Trip**. You will see by the accompanying illustration how terrific are the conditions met with. That the Auto-Meter, notwithstanding the obstacles, remains wholly **trustworthy** is only another proof of its unfailing reliability.

Auto-Meter Model M 1909

The Warner Auto-Meter Accurate At All Speeds

In all tests of endurance, in every kind of usage, the Warner Auto-Meter is the only speed indicator that can be trusted. It alone is *accurate at all speeds* and will remain accurate as long as you have a car to use it on.

The Warner Auto-Meter correctly indicates the slightest forward movement of the car and with equal accuracy *every range of speed* up to as fast as you dare to drive.

The Warner Auto-Meter, because of the Magnetic Induction principle upon which it works, is made so sturdy and strong, and with such refinements of construction, that practical tests have shown that it will withstand a MILLION MILES of the hardest kind of driving without appreciable wear or departing from absolute accuracy more than 10 *feet to the mile.*

We urge comparative tests.

Let us send you our Book, free, which tells about speed measuring instruments.

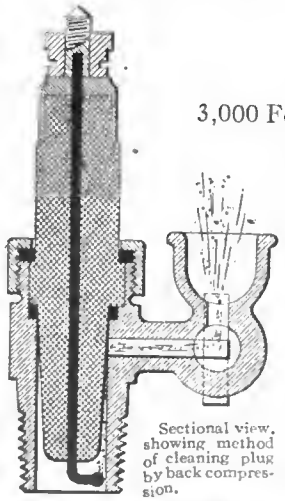
"ALL-IN-ONE" SPARK PLUG

Your motor is no better than the spark plug that makes the ignition—if the spark plug is good the motor is good—if the spark plug is bad the motor is bad, every time. So it behooves you to get a spark plug that is known to be right, that has its reputation already, that is making good 24 hours daily, 365 days in a year. **That** is the only kind of a spark plug you can afford to have.

This one spark plug, the one that has its reputation back of it instead of before it, is the

"ALL-IN-ONE"



Sectional view, showing method of cleaning plug by back compression.

3,000 Ford car owners use this spark plug and they are 3,000 "ALL-IN-ONE" enthusiasts. Any high-speed engine of any kind will be a better and more dependable engine by using these spark plugs.

The fastest motor boats in the United States use "ALL-IN-ONE" Plugs.

"ALL-IN-ONE" Spark Plugs are to be put on your motors and forgotten; they'll never need constant tinkering and adjustment, they'll take care of themselves. Put them on and leave them alone.

There is an "ALL-IN-ONE" Spark Plug for every spark plug purpose and they can be had from all dealers or from us direct **at $1.50** each.

To avoid delay kindly send money order or check with order.

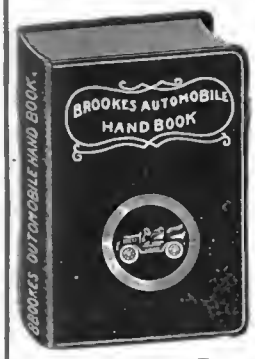
The AUTOMOBILE HAND-BOOK



By L. Elliott Brookes. 470 pages and over 180 illustrations. New 1909 enlarged edition. Popular edition, full leather limp, $1.50, postpaid.

A work of practical information for the use of Owners, Operators and Automobile Mechanics, giving full and concise information on all questions relating to the construction, care and operation of gasoline and electric automobiles, including Road Troubles, Motor Troubles, Carbureter Troubles, Ignition Troubles, Battery Troubles, Clutch Troubles, Starting Troubles. With numerous tables, useful rules and formulas, wiring diagrams and over 180 illustrations.

The perusal of this work for a few minutes when troubles occur, will often not only save time, money and worry, but give greater confidence in the car, with regard to its going qualities on the road, when properly and intelligently cared for.

It may be stated that at the present time nearly all automobile troubles or breakdowns may, in almost every case, be traced to the lack of knowledge or carelessness of the owner or operator of the car, rather than to the car itself.

The Class Journal Company, 231-241 W. 39th St. New York

The Practical Gas Engineer What To Do and How To Do It.
A book of 150 pages neatly bound in cloth. Sent postpaid for $1. Address Book Department, The Automobile, 231-241 W. 39th St., New York.

PRICE AUTO GLOVES

lead all auto gloves in style, dress and appearance, as well as sterling wearing qualities. They are made entirely from the best quality of selected, washable, horsehide leather, tanned by our special process under our own supervision. Every seam is sewed with the best quality of stout linen thread, making these gloves as nearly rip-proof as it is possible for gloves to be made. Price Auto Gloves are made to wear and they do wear.

Dealers interested in KASAN goods will find our line the best made anywhere, the dressiest and most durable. Blacks and Tans, short and gauntlet styles. Full out-seam gauntlets leather-bound.

On request, we will be glad to send our catalogue showing the complete line, in Horsehides and KASANS.

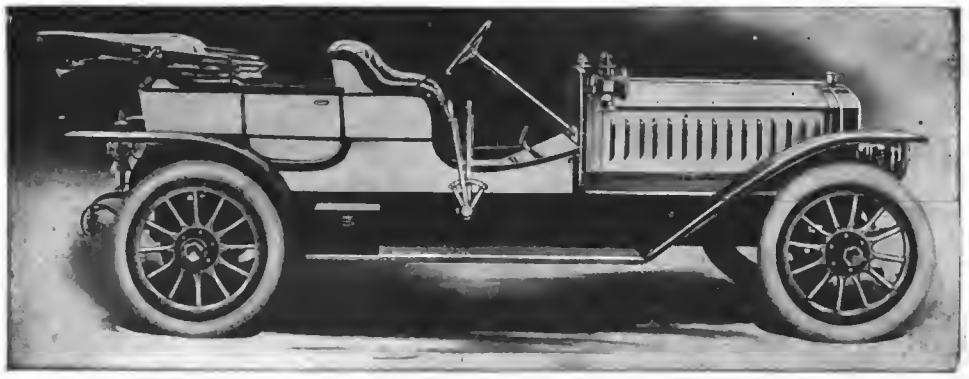
Chicago, 1720 Michigan Ave. New York, 875 7th Ave.

"The car that just suits everybody" has got to be a good car—a very good car—and there is no other that does this quite as well as the AUSTIN does. This pleasing condition didn't happen; it is the result of a firm, deliberate, predetermined intention to accomplish this very desirable end, and it has taken time and cash to bring it about. The AUSTIN is a car that squarely fills the need for as good a car as can be made at any price—yet in constructing AUSTIN cars manufacturing conditions exist that cheapen cost to the minimum without lessening quality one iota.

AUSTIN cars are no higher in price than the high-class American and foreign built cars, but even a casual examination will show them far greater value and far superior in every feature than any car built.

AUSTIN cars are for people who want quality—luxuriousness, style and perfect and easy operation, yet withal moderation in the matter of price. AUSTIN cars fulfill these conditions precisely, and if you contemplate buying a car, investigate "AUSTIN" cars carefully, and you'll find they are by far the "Cheapest" investment you can make. Seemingly a little high in first cost—but FIRST cost is all the cost—no endless expense in repairing this and replacing that, as in the low-grade cars.

At least get AUSTIN literature; it will greatly interest you, whether you buy or not.



Model 45, $3.000

Model 45, 45-50 H. P., 6-cylinder, 5-passenger Touring Car.....$3,000.00
Model 50, 50-60 H. P., 4-cylinder, 7-passenger Touring Car..... 4,000.00

Do You Belong to the "Maxwell" Family?

MAXWELL owners are a contented lot—for their's is a car to ride in, not to tinker over.

An owner's verdict is the final analysis of the value of an automobile. Since there are 14,600 satisfied MAXWELL owners it would be an easy matter for you to get an unprejudiced opinion.

The tour of the Maxwell Briscoe Motor Club is an indication of the confidence MAXWELL owners place in their cars.

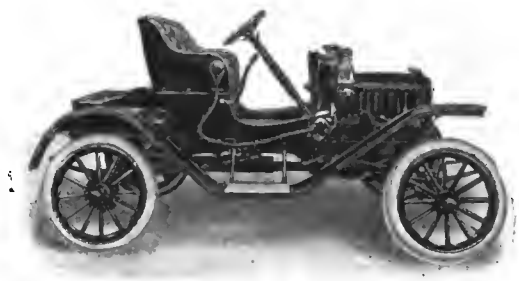
Over 30 MAXWELLS assembled at Columbus Circle on June 14th for a week's tour through the Berkshire Hills of Massachusetts, and over the roads of New York, Connecticut, Pennsylvania and New Jersey—a thousand miles in all.

MAXWELL owners feel the spirit of co-operation extended them by the men who make the MAXWELL.

Why don't you join the MAXWELL Family? Let me send you our catalog and other literature.

Yours very truly,

Benj. Briscoe President

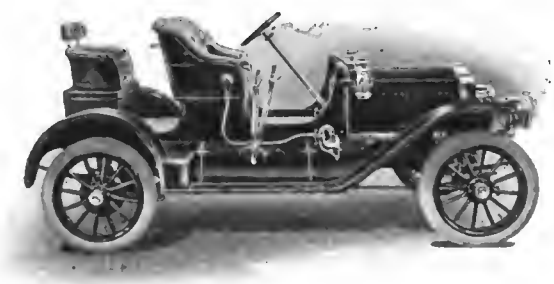


Model A—2 Cyl. 10 H.P.—$550

This standard American runabout costs only $550. It incorporates all the MAXWELL principles that have made these cars famous the world over. Equipped as per illustration with long fenders and running boards, oil lamps, etc.

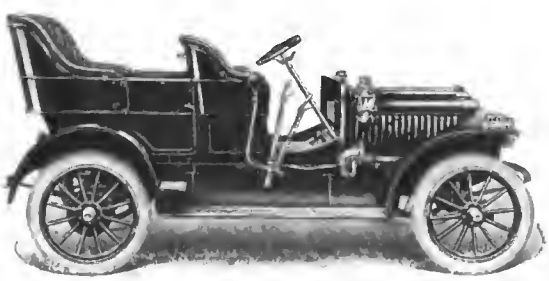
Maxwell Junior, $500

Equipped with plain mud guards only, oil lights, etc.



Model K. A.—4 Cyl. 30 H. P.—$1,750

A gentleman's roadster of "class," equipped with gas lamps, generator and magneto. Same chassis as famous 10,000 mile Non Stop car.



Model D. A.—4 Cyl. 30 H. P.—$1,750

A powerful five-passenger touring car, combining MAXWELL reliability with speed and comfort. Duplicate of the world's record holding 10,000 mile Non-Stop MAXWELL. Equipped with gas lamps, generator and magneto.

MAXWELLS range in price from $500 to $1,750. From 2-cylinder, 10 H. P. runabout to a big 4-cylinder 30 H. P. touring car or roadster. One of our six models will solve your automobile problem.

Quality Lamps

We have never, in all of our experience of thirty-five years in lamp making, found it desirable or business-like to make cheap, flimsy lamps to meet competition in price. The watchword has been *quality* regardless of price, but always under most favorable manufacturing conditions for cheapening cost. No material has ever been too high priced to be of use if it would enhance the quality of our output; no skimping has been done to save a few cents and endanger this quality; no workmanship deviating in the least from the very best has ever been allowed.

Every Atwood-Castle Lamp that has gone forth from our factory has been as good a lamp as the best brains, capital, facilities and experience can make it.

This strict adherence to *quality* has been the means of making us a reputation as lamp builders held by no other lamp-making concern on earth. We're proud of our line of lamps—*there are none better.* We say this without qualification of any kind. For whatever purpose you may need a lamp on your ear, there is an ATWOOD-CASTLE Lamp to fill the need, and it will fill the need better than any other lamp of any kind made by anyone.
